The part now before me (No. 5) contains two papers, one by Dr. Moritz Hoernes and the other by Mr. Josef Szombathy, both officials in the prehistoric department of the K.K. Naturhist. Hofsmuseum in Vienna. Dr. Hoernes describes five different groups of antiquities from the vicinity of Vukovar, on the south side of the Danube and not far from the great bend which the river makes in changing its course from south to east. One group consists of the débris of a settlement of the Stone Age, two—one being a hoard—are of the Bronze Age, while the remaining two are respectively interments of the Hallstatt period and of Slavish times (eleventh or twelfth century). The first station, which bears the name Vučedol, is considered of some importance inasmuch as its relics, especially the pottery, illustrate the evolution of ornament; and so the author discusses at some length the points of resemblance and difference between them and those of a number of other analogous stations, such as Butmir (Bosnia), Tordos (Transylvania), Sarvas, near Essegg (Slavonia), the lake-dwellings of Laibach Moor, &c. But as Dr. Hoernes' opinions on these matters are already known, or at any rate accessible, to archæologists through his great work on the history of prehistoric art in Europe ("Urgeschichte der bildenden Kunst in Europa," Wien, 1898). I shall pass on to the next paper, which, having an important bearing on the development of the early Iron Age in Europe, is of some consequence to British archæologists who may be desirous to trace the late Celtic remains of their own country to their proper source.

Mr. Szombathy's valuable monograph, "Das Grabfeld zu Idria bei Bača," takes the form of a report on excavations made, in 1886 and 1887, in forty-seven graves discovered in the valley of the Idria in the Julian Alps. The little cemetery, occupying an area of 5 to 10 metres in breadth and 30 metres in length, is situated on the right bank of the river some 20 metres above the river-bed and about an hour's walk to the south-east of the great necropolis of Santa Lucia—one of the most famous landmarks of the Hallstatt period in Europe. These graves had, on the average, a depth of one metre and a breadth and length of 50 to 80 centimetres; and all of them, with the exception of two, contained interments after cremation. They are numbered in the order in which they were excavated, but in the report they are described in chronological sequence beginning with the oldest, *i.e.* the middle Hallstatt period (about 600 B.C.). As this sequence comes down to late Roman times we have in the contents of the cemetery of Idria a remarkable evolutionary series of remains, extending over a period of nearly 1000 years. The successive stages of civilisation disclosed by the investigation, together with the number of graves assigned to each, are as follows:—Middle Hallstatt represented by 1 grave, late Hallstatt by 13, early La Tène by 2, middle La Tène by 13, late La Tène by 7, early Roman by 8, and late Roman by 2.

Mr. Szombathy's description of the relics, with 212 illustrations in the text, is a model of precision and brevity, without any lack of essential details, and therefore admits of no curtailment. The following remarks will, however, give readers some idea of their salient features.

Ornaments.—Among this class the fibulæ are the most interesting. One or two, of the boat-shaped type, having a long, straight foot, belong to the middle Hallstatt period. The Certosa fibula and its contemporary the cross-bow fibula are respectively represented by fourteen and three specimens. The La Tène fibulæ—early, middle and late forms—are numerous, and well worth careful study by those who have not acquired precise notions of the progressive stages thus designated. Five hinge fibulæ, peculiar to Roman remains, complete the list. Among the early La Tène group there are two very remarkable, if not unique, specimens. These are ornamented with amber beads placed in pairs on five pins projecting from the upper surface of the bow and attached to a bronze wire which, in a succession of small, graceful coils, follows the curve of the bow from head to foot. The middle La Tène specimens have the recurved foot ending in a circular expansion, which appears to have contained a setting of some kind of enamel. Iron fibulæ are scarce. The other objects of personal ornament consist of earrings, studs, finger-rings (one with three twists), bracelets with one or more coils, glass beads and torques.

Vessels.—Bronze caldrons and situlæ with movable handles, round or flat bottoms, and bulging, slanting or upright sides, are well represented. Two bronze dishes, one of the milk-plate type ($5\frac{1}{2}$ inches wide and $3\frac{3}{4}$ inches deep) and the other a small bowl with a ring-handle, have *graffiti* inscriptions on the outside of their rims, said to be in Venetic or old North Etruscan alphabet. A small bronze colander is perforated in such a manner as to form a geometrical pattern consisting of a central rosette surrounded by a fret border. Pottery is not abundant, and only a shallow dish, one or two jars with handles, and a conical vase with expanded base and slightly contracted mouth are figured.

Military Accoutrements.—A bronze helmet, with a projecting rim and central ridge, has an inscription in Roman characters scratched on it which reads *Protemus.*—There are also two iron helmets said to be of Roman workmanship. Among the weapons are a characteristic La Tène sword and sheath, both made of iron. Two other iron blades, also with their sheaths, are supposed to be like the Roman gladius. The iron blade in both specimens is separated from the grip (only the long tang of which now remains) by a circular guard of bronze. The sheaths were imperfect, but they appear to have been made of an iron frame, with panels of bronze and some non-durable material probably wood. There are also several spearheads, a knife-dagger still in its iron sheath and some fragments of shields showing conical bosses—all made of iron.

Industrial remains.—In this category are to be placed a

[1] "Mittheilungen der Prähistorischen Commission der K. Akademie der Wissenschaften in Wien." (Band i., No. 5, 1901.)

varied assortment of iron objects, such as knives, chisels, axes with flanges on one or both sides, axe-hammers with transverse sockets, scythes and sickles very similar to those from Oppidum La Tène, buckles, shears, shovels, ploughshares and coulters, the central portion of a bridle-bit, &c.

A bronze statuette.—One of the late Hallstatt graves contained a bronze figure of a beardless man, 12 centimetres in height. The body is clad in a closely-fitting tunic with a prominent girdle, leaving the neck, forearms and legs exposed. On the left arm is an armlet, on the left leg an anklet, and on the head a helmet. The bare feet rest on a small round pedestal. The gaze is directed to the palm of the upraised right hand, while the left arm is bent sidewards as if the half-closed fist were grasping the handle of an upright spear.

One of the most novel features of the cemetery was the proportionately large number of agricultural and domestic implements which it contained. While analogous cemeteries in other localities, such as the neighbouring necropolis of Santa Lucia, have yielded an endless array of objects of personal adornment, as well as others intended exclusively for votive purposes, here at Idria the grave-goods consisted of utensils, implements, weapons, tools and ornaments actually used in everyday life. Mr. Szombathy, however, observes that this peculiarity was more noticeable in the interments of the later half of the period during which the cemetery was in use.

Another equally noteworthy feature was that objects of different periods were not unfrequently found in the same grave—a fact accounted for by the tendency to continue old customs in secluded mountain valleys, such as that of Idria. This overlapping of different culture periods complicates, to some extent, the task of delineating the successive phases of the early Iron Age civilisation.

As to the racial question, Mr. Szombathy speaks by no means dogmatically. The earlier grave-goods indicate a civilisation so like that of Santa Lucia that its founders were probably of the Illyrian stock; but whether the same people continued in the Idria valley during the intrusion into it of the later Celtic and Roman culture-elements there is no evidence to show. Possibly the deciphering of the inscriptions on the bronzes, of which there are three or four, may help to solve the problem.

The frequency with which the generic expressions "Hallstatt" and "La Tène" are now used in the archæological literature of Europe renders it essential for British antiquaries to acquire precise ideas of the culture-elements represented by them. For the origin of the word "Hallstatt" we have to go back to the investigation of a cemetery in a small valley of the Noric Alps in the vicinity of Lake Hallstatt, and for that of "La Tène" to the well-known station of that name at the north end of Lake Neuchâtel. Subsequently these terms were used to designate similar remains found in widely-separated districts, just in the same way as the term "Mycenæan" is no longer restricted to the discoveries at Mycenæ. Practical researches have now greatly extended the culture-elements, both in number and types, which have to be classified under Hallstatt and La Tène, and it has often been mooted whether a better nomenclature could not be devised. I do not think it would now be advisable to make any change in this respect. What, however, is urgently required with regard to these terminal links in the development of the Iron Age in Europe is an authoritative work dealing with the essential characteristics of the relics discovered within their respective archæological areas. For records of the rich finds made in Central Europe since the appearance of "Das Grabfeld von Hallstatt" by v. Sacken, and in the cemeteries of Glasinac and Jezerine in Bosnia, as well as in those of the Istrian peninsula and the valley of the Po, we have to hunt in the *Transactions* of so many societies that they are, practically, inaccessible to all but a few specialists. Knowing the competency of Austrian archæologists for executing such a work, and the ample resources, by way of illustrations, at their command, I trust this suggestion will not remain fruitless.

ROBERT MUNRO.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE difficulty in connection with Mr. Carnegie's offer to found a National University (see p. 164) has been solved by the donor's arranging to convert into Government bonds the ten million dollars' worth of United States Steel Corporation bonds, the acceptance of which was an obstacle to the adoption of the scheme.

OUR national deficiencies in regard to provision for higher scientific and technical education are obvious to all who take the trouble to inquire into the matter. For many years men of science have been watching with a feeling akin to envy the opportunities provided for scientific instruction and investigation by foreign nations, and comparing them with the elementary efforts at technical education here. The facts which have been given in these columns week after week have made our readers familiar with existing conditions of technical education; and it is impossible not to be dismayed at the country's prospects in the industrial wars of the future when the inadequate way in which our industrial leaders are trained is understood. A pamphlet just published by the Association of Technical Institutions, giving a comparison of technical education at home and abroad, again brings the subject before the attention of the public. In the matter of buildings and equipment for the highest kinds of technical work we are still far behind Germany, Switzerland and America. Two diagrams published in Nature in 1898 (vol. lviii. p. 54) show clearly how Continental institutions for instruction and research work in technical or applied science are provided on a scale which vastly exceeds ours both as regards areas of sites and areas of buildings. Both these diagrams are reproduced in the pamphlet just mentioned, and also those which

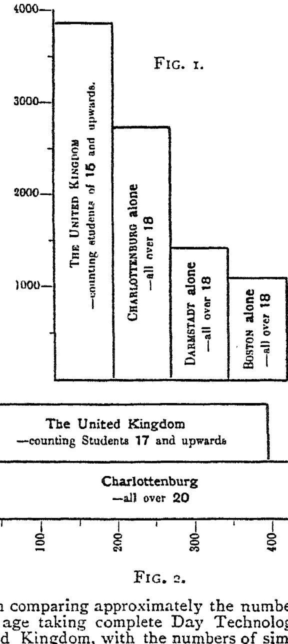

FIG. 1.

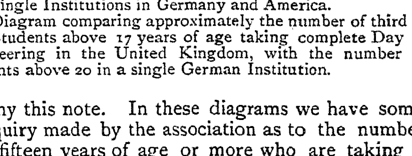

FIG. 2.

FIG. 1.—Diagram comparing approximately the number of Students above 15 years of age taking complete Day Technological Courses in the whole United Kingdom, with the numbers of similar Students above 18 in single Institutions in Germany and America.

FIG. 2.—Diagram comparing approximately the number of third and fourth year Students above 17 years of age taking complete Day Courses in Engineering in the United Kingdom, with the number of similar Students above 20 in a single German Institution.

accompany this note. In these diagrams we have some results of an inquiry made by the association as to the number of day students fifteen years of age or more who are taking complete regular day technological courses of not less than twenty hours a week. Statistics were obtained from Universities, University Colleges, technical schools and all similar institutions where day technological courses are given. The results of the inquiry show that in comparison with other countries our attempts at technical education are utterly futile. In the whole country there are only 555 third-year students of technology satisfying the conditions described, and 113 fourth-year students. The total number of third-year students in engineering is only 347, and of fourth-year students 52, and this number is only obtained by counting students who begin their studies at the immature age of fifteen. As the accompanying diagram (Fig. 1) shows, there are more than two-thirds as many regular day students above eighteen years of age at the Charlottenburg Technical High School, Berlin, as there are above fifteen years of age taking

complete day technological courses in the whole of the United Kingdom. If only day students of technology more than eighteen years of age are considered, there are less in our country than in any large technical institution in Germany or America, as indicated in Fig. 2. With facts like these to consider, the future of our country cannot be contemplated without misgiving. When will our political leaders take up the subject of secondary and technical education seriously, and insist upon proper provision being made for it by greatly increased funds from national and local sources? The apathy displayed in regard to technical training by both employers and employed is largely due to the drifting policy of the Government and the sacrifice of future interests to present expediency.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 5, 1901.—"Preliminary Account of the Prothallium of Phylloglossum." By A. P. W. Thomas, M.A., F.L.S., University College, Auckland, N.Z. Communicated by Prof. G. B. Howes, F.R.S.

The sporophyte generation of *P. Drummondii* is a small plant, growing from a tuber, which forms a tuft of a few cylindrical tapering leaves. The tuber is apparently comparable to the protocorm of *Lycopodium cernuum*, except that it is repeated annually on the formation of a new protocorm. The prothallia have been obtained amongst the parent plants, and very special conditions, which are not of regular annual occurrence, are necessary for germination of the spores, the most important being the presence of a fungus with which the prothallium lives symbiotically, like that of the Lycopods. One of the simplest prothallia observed consisted of an oval tuber below, with a simple cylindrical shaft with rounded apex, akin to that of the oldest prothallium of *L. cernuum* described by Treub. In older prothallia the crown is commonly separated by a slight constriction from the much enlarged body, which bears the embryo on one side. Below this swollen part the body contracts to a cylindrical shaft, which passes downwards and swells out again to terminate in the primary tubercle, from which more especially rhizoids are produced.

The prothallia are monœcious, and the archegonial necks, which vary from two to twenty in number, are a conspicuous feature of the crown. The oosphere lies at a little depth below the surface layer, and the antheridia are sunk in the crown, with their enclosed cavities elongated at right-angles to the surface. The sex-organs would seem to resemble those of *L. cernuum* more closely than those of any other species of Lycopodium.

Studied by means of microtomic sections, the development appears to be also much like that of *L. cernuum*. The embryo grows obliquely downwards and outwards, the part near the archegonial venter is the foot, and at the opposite end are the stem-apex and leaf, the tip of the leaf being the first part of the embryo to appear outside the prothallium. Immediately on escaping from the prothallium the embryo forms a protocorm, apparently in the same manner that the adult plant forms its annual tuber. The pedicel of the tuber elongates downwards until the latter is placed at a safe depth. In the meantime the leaf grows up, and although no root-formation has been observed during the first year, rhizoids may be developed on the pedicel and protocorm. The leaf becomes green even before it escapes from the prothallium, and as soon as it reaches a little above the soil stomata are formed, and a slender strand of tracheids in the centre. The first protophyll has the structure of a small leaf as produced in later years, and the later development of the sporophyte appears to be slow, the plant coming up in many cases a second and a third year with only a single leaf. A young prothallium was found quite colourless, except for a yellow tinge at the upper end, while two others still without sex-organs bore but scanty chloroplasts. But never was there a fully developed prothallium which was not green above. The prothallium is distinctly of Lycopod type, on the whole most nearly resembling that of *L. cernuum*, except that it lacks the leaf-like assimilatory lobes of this, and the simplicity of structure favours the view that Phylloglossum is a primitive form of Lycopod. It is recognised as a permanently embryonic form, but the simplicity of structure of the mature saprophyte does not necessarily prove it to be a primitive form of the Lycopodiaceous phylum.

Branching occurs in two ways. The spike or strobilus occasionally branches, and the branching always takes place above the lowest sporophyll, sometimes at the base of the spike or even near the apex of the strobilus. Even when the strobilus forks there is no transition of form between sporophyll and protophyll, and such leaves as have been observed on the peduncle some distance below the rest of the strobilus have always been of sporophyll type. Twenty was the largest number of protophylls found on a plant, but there is never a transition between protophylls and sporophylls. The view is entertained that the former may have arisen from the differentiation of the lower region of a sporogonium or its homologue, in which this region had acquired sterilised tissues, and that the sporophylls arose from the upper fertile region of the sporogonium. There appears to be no connection between the number of protophylls and reproduction by spores. The formation of two new tubers is common, and these may be found on opposite sides of the plant in a manner favourable to dispersion.

Phylloglossum is not semi-aquatic. It may grow upon a hill-top and as well upon a slope, and it was never found in actual swamp. There is little evidence that it owes its simplicity to reduction, and it is regarded as possibly the most primitive of existing Pteridophytes, while the simple character of the gametophyte and comparison of the mature sporophyte with the embryo of *Lycopodium cernuum* favour the view that it is the most primitive of existing Lycopodinæ.

The author has finished and despatched to London an elaborate and fully illustrated memoir upon this most important organism.

December 12, 1901.—"Contributions to the Chemistry of Chlorophyll. No VIII. Changes undergone by Chlorophyll in passing through the Bodies of Animals." By Edward Schunck, F.R.S.

The conclusions to which the experiments described lead are summarised as follows:—

(1) The fæces of animals supplied with green vegetable food only—such at least as have so far been examined—contain no chlorophyll, but in its place substances which must be supposed to be derivatives of chlorophyll, formed partly by the action of acids on the chlorophyll of the food, partly by some agency to which the latter is subjected in its passage through the body.

(2) Of these substances, one seems to be identical with phylloxanthin, a well-known product of decomposition of chlorophyll. Another is a substance of well-marked properties, nearly resembling, but not identical with, phyllocyanin. It has not, so far as the author's experience goes, been hitherto observed as a result of any process of decomposition to which chlorophyll has been subjected outside the animal body. He considers it as a body *sui generis*, characterised by its fine purplish-blue colour and its brilliant metallic lustre. The existence of other products in addition to these two is possible. On one occasion, indeed, a definite crystalline substance was obtained, which seemed to be peculiar, but that it was in any way connected with chlorophyll could not with certainty be maintained.

Royal Astronomical Society, December 13, 1901.—Dr. J. W. L. Glaisher, president, in the chair.—The secretary read a paper, by Prof. S. C. Chandler, on Sir G. Airy's reflex zenith tube. The history of this instrument had passed through various phases—in the beginning of great hopes, later of grievous perplexity, and finally of severe disappointment. All attempts to obtain parallax or the constant of aberration produced quite discordant results, and the observations had at last been practically abandoned. But Dr. Chandler now showed that these anomalous results were due to the relative motions of the earth's axes of rotation and figure discovered by him some ten years ago, and that the zenith-tube observations, so far from being useless, had provided us with an invaluable record of these phenomena. An analytical proof of these statements was given in the paper.—Prof. R. A. Sampson gave an account of the original MSS. of the late J. C. Adams on the perturbations of Uranus between the dates 1841 and 1846. It was shown that Adams made no less than six different solutions of the problem in this period, and that the first, completed in 1843, was much more complete than had been supposed.—Prof. Turner read a paper on a simple method of accurate surveying with an ordinary camera, in which he showed that results of great accuracy could be rapidly obtained by the photographic method.—Mr. Hinks gave a paper on the accuracy of measures on photographs,

especially in reference to recent papers on the subject by M. Lœwy and Mr. H. C. Plummer.—Other papers were taken as read.

Zoological Society, December 17, 1901.—Prof. G. B. Howes, F.R.S., vice-president, in the chair.—A communication was read from Mr. G. Metcalfe, M.A., of New South Wales, concerning the reproduction of the duckbill (*Ornithorhynchus anatinus*). The author stated that he was of opinion, after many years' observation of the animal, that the duckbill was viviparous and that the young were not, as was generally supposed, hatched from the eggs after they had been deposited.—Dr. C. I. Forsyth Major exhibited the skull of a fossil aquatic musteline animal, *Enhydrictis galictodes*, gen. et sp. nov., from the Pleistocene ossiferous breccia of the island of Sardinia, which he stated had affinities with both the neotropical Galictis and with the genus Trochictis from the Middle Miocene of European deposits.—Mr. J. S. Budgett read a paper (illustrated with lantern slides) on the structure of the larval Polypterus. His observations confirmed the belief that the Crossopterygians were a very generalised group of vertebrata, and he concluded that the particulars of structure in which other more recent groups agreed with these ancient types were probably of a primitive rather than of a secondary nature.—Mr. L. A. Borradaile read a paper on the spawn and young of a polychæte worm of the genus Marphysa from Ceylon, allied to, or identical with, *Marphysa teretiuscula*, Schmarda.—Dr. P. Chalmers Mitchell read a paper on the anatomy of gruiform birds, with special reference to the correlation of anatomical characters. The communication was based on dissections of birds belonging to the Rallidæ, Gruinæ, Araminæ, Psophiinæ, Dicholophidæ, Otididæ, Rhinochetidæ, Eurypygidæ and Heliornithidæ, the material consisting chiefly of birds that had lived in the Society's gardens.—Prof. F. G. Parsons read the first portion of a paper, prepared by himself and Prof. B. C. A. Windle, F.R.S., on the muscles of the Ungulata. This part dealt with the muscles of the head, neck and fore-limbs of these mammals.—Mr. F. E. Beddard, F.R.S., gave an account of the minute structures in the spermatophores of the earthworms of the genus Benhamia.—Mr. G. A. Boulenger, F.R.S., read some further notes on the African batrachians which he had recently described under the names *Trichobatrachus robustus* and *Gampsosteonyx batesi*. A communication was read from Dr. A. G. Butler consisting of a list of thirty species of butterflies of which specimens were contained in a collection sent home by Major A. H. Cowie, R.E., from St. Lucia, West Indies. One of the species was new to science, and was described under the name of *Cystineura cowiana*.

PARIS.

Academy of Sciences, December 23, 1901.—M. Fouqué in the chair.—On the periods of double integrals, by M. Émile Picard.—On the cultivation of clover on soils deprived of lime, by MM. P. P. Dehérain and E. Demoussy. The experiments described furnish two interesting examples of the influence of inoculation and of the medium on the growth of Leguminosæ; the clover grows in the soil of Brittany whenever lime and phosphates are used, that is, as soon as the medium becomes favourable to its vegetation; it remains poor, on the other hand, in a heath soil, in spite of the creation of a favourable medium, because garden earth does not carry the necessary bacteria.—Remarks by M. Bouquet de la Grye on the work done by the third general conference of weights and measures.—Remarks by M. E. Guyou on the annual of the Bureau des Longitudes for 1902.—On the measurement of the meridian of France by Méchain at the end of the eighteenth century, by M. G. Bigourdan. If to the measurements of Méchain, which formed the basis of the metric system, the corrections of Delambre are applied, the results are brought more nearly into line with the recent observations of Perrier.—On the observation of the annular eclipse of the sun of November 11, 1901, by M. A. de la Baume-Pluvinel. The observations, which were partly photographic and partly ocular, were made in Lower Egypt. Owing to the early hour at which the eclipse took place the ocular observations were the most satisfactory. One point to which especial attention was directed was the examination of the spectrum of the sun in the neighbourhood of the edge of the moon. A thickening of some of the Fraunhofer lines here would indicate the existence round the moon of a gaseous atmosphere capable of producing a sensible absorption. But no evidence of such a thickening could be obtained either from the negatives or from the direct observations, thus confirming the absence of a sensible atmosphere round the moon.—Remarks on the note of M. de la Baume-Pluvinel, by M. J. Janssen.—The calculation of real roots of equations, by M. A. Pellet.—The progressive calculation of the integrals of certain differential systems, by M. Riquier.—On the separation and calculation of the real roots of equations, by M. Raoul Perrin.—On the numbers e and π and transcendental equations, by M. Edmond Maillet.—On the most general motion of a solid body which possesses two degrees of freedom round a fixed point, by M. René de Saussure.—The laws of electrical energy, by M. E. Carvallo. A criticism of the two laws enunciated by Maxwell.—On a new application of optical observations to the study of diffusion, by M. J. Thovert. The two solutions are superposed in a plane-sided box and the deviation of a horizontal light ray measured. The deviation is proportional to the rate of change of the concentration with the vertical ordinate. The diffusion of a solution of sodium chloride into water was measured by this method and the results were found to be in accord with the theoretical expression.—Contribution to the study of Geissler tubes in a magnetic field, by M. H. Pellat.—The cooling power and conductivity of air, by M. P. Compan. An experimental determination of the velocity of cooling of a blackened copper ball in dry air at different pressures. The velocity of cooling could be expressed by the formula of Dulong and Petit for pressures between 760 mm. and 15 mm.; for pressures below this the rate of cooling falls off much more rapidly than would correspond to this formula.—Observation of an antisolar corona on the Puy de Dôme, by M. Bernard Brunhes.—On a petroleum ether thermometer, by M. L. Baudin. By the use of a light petroleum ether possessing a density of 0·647 at 15° C., a thermometer can be constructed which does not solidify at the temperature of liquid air, and which can be used to measure temperatures down to that point. It was graduated at four fixed points, the boiling points of oxygen, nitrous oxide, methyl chloride and the melting point of ice.—On the dilution constant of saline solutions, by M. Albert Colson.—On metallic strontium and its hydride, by M. Guntz. Strontium can be prepared by the electrolysis of an aqueous solution of strontium chloride with a mercury kathode and then driving off the mercury from the amalgam by very cautious heating. Heated in hydrogen at a moderately high temperature it forms a hydride, fusible at a red heat of the composition SrH_2. The properties of strontium resemble those of barium, except that strontium does not appear to form an ammonium compound with liquid ammonia.—On the plurality of the blue oxides of molybdenum, by M. G. Bailhache.—On methylene chlorobenzoate and dibenzoate, by M. Marcel Descudé. These two compounds are obtained simultaneously by the action of benzoyl chloride upon trioxymethylene in the presence of zinc chloride.—On the hyposulphites of the aromatic amines, by M. A. Wahl.—Some new reactions of the organo-metallic derivatives. Synthesis of ketones, by M. E. E. Blaise. Magnesium organo-derivatives react with nitriles to form compounds immediately decomposable by water with the formation of ketones. The reaction appears to be gen.ral, and details are given of the preparation of ethyl-*o*-tolyl ketone, benzyl-*n*-propyl ketone, benzylisoamyl ketone, *o*-methyldesoxybenzoin, *n*-butyl-*p*-tolyl ketone, *n*-propyl-*p*-tolyl ketone, *n*-propylisoamyl ketone, ethyl-propyl ketone and ethylphenyl ketone. The semicarbazides of these ketones were also prepared, and their melting points are given.—On the basic properties of oxygen and its quadrivalency in the xanthene series, by M. R. Fosse.—The action of normal propyl and butyl alcohols upon their sodio-derivatives; the synthesis of dipropyl and dibutyl alcohols, by M. Marcel Guerbet.—The study of fermentation amyl alcohol, by M. G. Bemont. Fermentation amyl alcohol boils at 131° and gives on oxidation a valeric acid boiling at 175°, probably methyl-ethylacetic acid.—On the variation of the kidney and its excretion in fowls fed with meat, by M. F. Houssay. Under a meat diet the urea excreted is nearly three times the amount with a grain diet, and the kidney would also appear to increase in weight by about one-third.—A new contribution to the search for the typhoid bacillus, by M. R. Cambier. The author has shown in a previous note that the typhoid bacillus can make its way fairly readily through the walls of a porcelain filter immersed in a nutrient broth. The *Bacillus coli communis*, which is also very mobile, can grow through the walls in a

similar manner. In the present paper an account is given of an attempt to diminish the mobility of the latter bacillus by the addition of alkali and common salt. Particulars are given of an application of these facts to the determination of the presence of the typhoid bacillus in drinking water.—Study of the variations of the organic matter during germination, by M. G. André.—A method for separating glutamic acid and leucine by means of hydrochloric acid gas, by M. A. Étard.—On the bluing of certain fungi, by M. Gabriel Bertrand. On breaking certain fungi of the genus Boletus, the tissue exposed to the air takes on a fine transient blue colour. It is shown that this effect depends on six different factors: the substance boletol, the oxygen of the air, laccase, manganese, water and a metal belonging to the series of the alkalis or alkaline earths.—On the root of Iboga and ibogine, by MM. Lambert and Heckel. A physiological study of the active principle of Iboga. The alkaloid ibogine possesses anæsthetic properties resembling those of cocaine.—An attempt at the measurement of cytological activity, by M. Rémy Saint-Loup.—Observations on the root nodosities in the Leguminosæ, by M. Émil Laurent.—The causes of sterility in peaty soils, by M. J. Dumont.—A new case of variation in the vine following mixed grafting, by M. A. Jurie.—On the aging of the embryo in the Graminaceæ, by M. Edmond Gain.—On the refracting globules of the chlorophyllian parenchyma of leaves, by M. Louis Petit.—Considerations on the sexuality of certain yeasts, by M. A. Guilliermond.—Proof of the existence of the Trias in Greece. The stratigraphical position of the Cheli limestone, by MM. L. Cayeux and Ed. Ardaillon.—Observations on the synclinal of Amilie-les-Bains, by MM. Léon Bertrand and O. Mengel. The dislocation in the quartz at Éveaux and at Saint-Maurice (Creuse), by M. L. de Launay.—On a new Miocene layer in the interior of Corsica, by M. E. Maury.—Some new proofs relating to the contamination of the springs in the chalk in France, by M. Martel. The case is considered of streams which flow above ground for some distance and become polluted and then disappear into fissures of the chalk, and after undergoing a certain amount of filtration reappear in the form of springs. Confirmation is given of the possibility of danger from this source.—On the project of crossing the Sahara by balloon, by M. Deburaux.

NEW SOUTH WALES.

Royal Society, November 6, 1901.—Mr. H. C. Russell, C.M.G., F.R.S., president, in the chair.—The following gentlemen were elected hon. members of the Society:—Prof. J. W. Judd, C.B., F.R.S., Prof. Simon Newcomb, and Sir Benjamin Baker, K.C.M.G., F.R.S.—The Clarke memorial medal for 1901 was awarded to Mr. Edward John Eyre, Walreddon Manor, Tavistock, England, for his exploring work.—The Thurrawal language, by Mr. R. H. Mathews. In this paper the author describes the structure of the native speech of the aborigines of the region between Jervis Bay and Port Hacking. An appendix exhibits the elements of some other dialects adjoining the Thurrawal tribes on the north and west, the whole concluding with an extensive vocabulary.—Note on the sesquiterpene of Eucalyptus oils, by Mr. Henry G. Smith. In this paper the author showed that a sesquiterpene occurs in many Eucalyptus oils and that it is this constituent that gives the pink coloration to Eucalyptus oil when testing for eucalyptol with phosphoric acid.—Current papers, No. 6, by Mr. H. C. Russell, C.M.G., F.R.S. In the year November 1900 to November 1901, 130 current papers were received, and these form the basis of the present paper. In this list there was a marked increase on the tracks Sydney to Canada and United States. Previously very little was known of the drift of bottle papers in that sea; but during this year an appreciable increase of interest has been manifested in the current papers found amongst the islands. These show very clearly the presence of a very rapid current near the equator, somewhat similar to that in the Indian Ocean. For instance, current paper 598 made daily a drift near Fiji of 11·1 miles per day; near Gilbert Island, No. 671 travelled at the rate of 19·5 miles per day; and near Phœnix Island the current paper No. 674 travelled 16·8 miles per day; and so on. At first it seemed that current papers aggregate in certain months, but upon the monthly papers which have been received in five years there is not much to support the idea. But there is good reason to believe that the current paper is affected by the wind as well as by the currents, and that strong persistent winds alter the landing places of current papers.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 2.

RÖNTGEN SOCIETY, at 8.30.—On the Function of an Auxiliary Electrode in X-Ray Bulbs: C. E. S. Phillips.—On Radiography applied to Dental Surgery: Prosper H. Marsden.—Mr. H. W. Cox will demonstrate a New Method he has devised for exciting Several Tubes simultaneously from One Coil.

FRIDAY, JANUARY 3.

ANALYSIS OF MEMORY.

Memory: an Inductive Study. By F. W. Colegrove, Ph.D., D.D., Professor of Philosophy in the University of Washington. With an introduction by G. Stanley Hall, LL.D. Pp. xi + 369. (London: G. Bell and Sons. New York: Henry Holt and Co., 1901.) Price 6*s.* net.

THE title of this book—"An Inductive Study"—leads us to expect an exposition of fundamental and derivative generalities based on a logical arrangement of thoroughly criticised facts. Facts and generalities there are in plenty, but the criticism is not adequate, neither is the arrangement conspicuously logical. The result is that, in spite of Dr. Stanley Hall's commendation, the book as a whole leaves on one an impression of chapters loaded with detail yet not adding much to the scientific study of memory. Prof. Colegrove has taken great pains, but he has attempted too much in a small book, and his standpoint is neither frankly scientific nor frankly popular. In Chapter i.—"Historical Orientation"—he makes a rapid sweep from the Greeks to the moderns, indicating the transit from the unsystematic *aperçus* of the earlier schools to the positive methods of the later. The conception is good, but the space available makes even a tolerable sketch impossible. Even the characterisations given are sometimes more than doubtful. It is quite inaccurate, for instance, to say that in contrast with Kant's "masterly analysis of mind," "Reid, Stewart and Hamilton are wholly metaphysical" (p. 10). Then, the account of Bain's formula for the nervous seat of reproduced feelings—"the renewed feeling occupies the very same parts, and in the same manner, as the original feeling, and no other parts, nor in any other assignable manner"—becomes "mental impressions depend upon the renewal of the feeling which accompanies the same part and in the same manner as the original feeling" (p. 14), which is practically unintelligible. Badly done summaries are worse than none, and the above—which involves a fundamental doctrine—does not alone suffer by the compression. The references, however, are, as a rule, given; the student will therefore not be misled, but the general reader also would prefer accuracy in his "orientation."

In Chapter ii.—"Biological Orientation"—we have a mass of facts, partly anecdotal, about animal intelligence generally, instincts, habits, natural selection, memory and some other things. The purpose is to lead up to the general theory of "organic memory" (Hering) and "racial memory" (p. 89). We are left without any clear conception as to whether "racial memory" implies (*a*) cumulative use-inheritance (Spencer), or (*b*) selected variations (Weismann). The difference is said to be "in part a war of words" (p. 87). Possibly, but the words are of Sibylline importance. "Organic memories refer to the ability to conserve racial experiences by a congenital modification of the organism" (p. 90) leaves the question very much an open one, even if the wording were unexceptionable. The use made of "racial memory" and "organic memory" elsewhere makes one long to have Locke's onslaught on "innate ideas" written up to date.

In Chapter iii.—"Diseases of Memory"—Prof. Colegrove recapitulates familiar clinical facts regarding word-blindness, word-deafness and other forms of aphasia. He adds one or two striking records of traumatic loss of memory with gradual recovery (pp. 126 *et sqq.*), and illustrates the theory of "inhibition" amnesia. His general conclusion that Ribot's "law of regression" demands modification, if, indeed, it holds at all, is not borne out by the cases he records. There is as much difference between the physiological sequence in normal memory decay and the shattering due to gross lesions like cerebral hæmorrhage as there is between progressive muscular atrophy and a broken leg. To make the sporadic dissociations correlated with hæmorrhage illustrate the normal sub-involution of progressive senility requires much more minute evaluation of clinical facts than we get here. The work of M. Pierre Janet would have assisted Prof. Colegrove to what we mean, but he nowhere refers to Janet.

The next chapter—"Brain and Mind"—could not, perhaps, be avoided, but it should have been reduced. Prof. Colegrove, however, takes the "correct" attitude towards the metaphysical theories he mentions, namely, that they are not in the province of psychology. The formula of "genetic parallelism," which simply means that mind and body emerge together and develop together, and "functional interaction," which means that now the physical, now the psychical, is uppermost, may be accepted as a variant on the "double-faced unity" or "parallelism" theory; but in Chapter v. the mode of expounding this relationship frequently lapses, verbally if not in content, from its presuppositions. On p. 176, where it is held that (*a*) the "neural discharge" and (*b*) the "conscious element" may, each on occasion, "take the initiative," the language seems to imply that the "conscious element" is wholly divorced from any "neural discharge." This transit in terminology from physical to psychical and *vice versâ* is made again and again. The general result of the chapter is that there are "memories," not a "memory" (p. 198). This, however, is only to say that the various grades of the nervous system have each their appropriate variety of retentiveness and reproduction. In his exposition the author plays off "organic memory" against the more limited psychological "memory." He does not maintain much order in his sequence of "memories." Nor is his language always exact. That "muscular memories depend *chiefly* upon the nervous system" (p. 198) suggests a question that is not solved by the following sentence:—

> "By exercise a muscle acquires new power, which is due in part to a change in the muscles themselves, but such memories are associated with the nervous system. This is possible because the motor nerve terminates in the centre of the muscles and throws off branches in all directions" (p. 199).

There is not much "orientation" here. Prof. Colegrove would have profited by a more intensive study of the good "psychologies," which would have enabled him to use the matter of this chapter to more purpose.

In Chapter vi.—"Individual Memories"—we have the

only "inductive" effort in the book. The chapter contains a large number of moderately well-sifted facts. The author's *questionnaire* included 1658 persons of various ages and races. Some of the facts are valuable, but they are not so arranged as to elicit any striking generality. They are, indeed, like the "facts" of many other *questionnaires*, apt to be the bad observations of untrained observers. The minute study of a few cases would have been more fruitful of "inductions" than these somewhat content-less percentages of commonplace recollections. One reasonably looks for more from an "inductive" study than this on the question of "taking notes":—"There is a wide diversity of opinion as to how full notes a student should take, and almost all degrees of copiousness are indicated" (p. 270). The true inference is that most students are poor psychologists. The extremely varied suggestions for teaching a "boy to remember things *on time*" (p. 271) only show that practical pedagogy in America, as elsewhere, is more ready to punish the boy than to study his mind—punishment being as effective, on the average, as it is useless in some particular cases.

Chapter vii.—"Apperception and Association"—includes sections on recognition times, attention and interest. This chapter is one of the best in the book. The essence of Chapter viii.—"Pedagogical Applications"—is that good memory depends on attention and the attentive multiplication of associations. There is not much novelty.

Of the book as a whole, it must be said that it suffers, in every chapter, from a want of clear definition of terms and a clear analysis of the phenomena to be investigated. The references, however, are valuable and the bibliography is good. W. LESLIE MACKENZIE.

A LUNAR ROMANCE.

The First Men in the Moon. By H. G. Wells. Pp. 312. (London: George Newnes, 1901.) Price 6*s.*

IT is many years now since Jules Verne wrote his imaginary account of a journey to the moon. He supposed a party of three men enclosed in a projectile shot by a huge gun towards the moon, which they never reached; they fell back to earth and escaped in a marvellous manner to tell the tale. The work was imaginative enough to hold the attention, but full of scientific blunders and improbabilities of the most glaring character. Mr. Wells has produced a book of a very different character; he has made himself master of the little we know about the moon, and thought out the possibilities with the greatest care, and the result is a narrative which we will venture to say is not only as exciting to the average reader as Jules Verne's, but is full of interest to the scientific man. We do not mean that the astronomer is likely to learn any new facts from this *résumé*, for which he himself furnished the material; but he will be astonished to find how different the few scientific facts with which he is familiar look in the dress in which a skilful and imaginative writer can clothe them, and it is worth reading the book with minute care to see if one cannot catch Mr. Wells in any little scientific slip. Some writers are so easy to catch that the game is not worth playing; but Mr. Wells is a worthy opponent, and we are glad to see that his scientific rank has been recognised by the Royal Institution, who have invited him to lecture on January 24.

The visit to the moon is made possible by the discovery of a substance (cavorite) impervious to gravitation. This interesting property comes to cavorite only at a critical temperature (60° F.), after "the paste has been heated to a dull red glow in a stream of helium," and the suddenness with which the imperviousness arrives causes interesting events at first. When the new conditions are better realised, a glass sphere is built and covered with cavorite blinds which can be put up or down. When all are down the sphere is entirely free from attraction, and when any particular blind is up it is only attracted by the stars or planets seen in that direction. It is obvious that in these circumstances a comfortable voyage through space is manageable. The two occupants of the sphere journey to the moon and land upon it near the terminator, on a snow drift of frozen air. With sunrise they find that the air melts and evaporates, and there is enough for them to breathe, so that they emerge from the sphere. They find their weight a trivial matter and leap twenty or thirty yards at a step, and a wonderful fungus vegetation springs up before their eyes. In the exhilaration of exploring they lose their sphere and are thus thrown on their own resources. Presently they come across the Selenites, who emerge from the interior of the moon, where they have been spending the lunar night. The first to emerge are those herding the moon calves—great beasts 200 feet long, that browse in a vividly described and rather disgusting manner ("like stupendous slugs") on a speckled green mossy plant. The cowherd was a "mere ant" by comparison, and the intelligent Selenites generally turn out to be a sort of insect, varied physically in a grotesque manner at will. After various adventures in and on the moon, one of the voyagers recovers the sphere and gets back to earth; the other stays in the moon and sends messages by ethereal telegraphy describing it more fully; and the interest never flags throughout. Following similar writings, Mr. Wells sometimes allows himself a sly hint at terrestrial matters in describing lunar affairs. He describes a lunar artist thus (p. 302):—

"Love draw. No other thing. Hate all who not draw like him. Angry. Hate all who draw like him better. Hate most people. Hate all who not think all world for to draw."

And two pages on there is a similar burlesque description of a mathematician. It is even easier to see the point than to find the pun in the following:—

"And since the density of the moon is only three-fifths that of the earth, there can be nothing for it but that she is hollowed out by a great system of caverns. There was no necessity, said Sir Jabez Flap, F.R.S., that most entertaining exponent of the facetious side of the stars, that we should ever have gone to the moon to find out such easy inferences, and points the pun with an allusion to Gruyère . . ."

Of a book so full of unfamiliar things it is impossible to give a complete account. We will conclude this notice by heartily recommending the book to readers both scientific and unscientific, and by giving, with a triumph

not free from trepidation, an instance where we think Mr. Wells has been caught napping. When the cavorite blinds are closed and the sphere starts on its journey, he describes the curious effects of the absence of external gravitational attraction—all the material occupants of the sphere slowly collect in the interior by their *mutual* attractions, and there is no "up" or "down." Then a window is opened towards the moon and promptly everything gravitates towards the moon—the direction towards the moon is *down*wards, though the attraction is slight. Surely this is a slip? With bodies moving freely in space only the *differential* attraction would be felt, and this would be negligible compared with the mutual attraction of the occupants of the sphere. Even if it were not so small it could not act in the manner specified; its tendency would be to *separate* bodies (as in the case of the tides), not to bring them together, and thus a man near a "floor" would not fall towards it but would rise from it. But Mr. Wells is so wonderfully careful in general that we make this criticism with far less confidence than we should have felt in another case; we have an uneasy feeling that he may dexterously transfer the supposed slip from his account to ours.

A POPULAR WORK ON FISHES.

The Story of Fish Life. By W. P. Pycraft. Pp. 210. (London: G. Newnes, Ltd., 1901.) Price 1s.

THIS book, which is one of the shilling series published by Messrs. Newnes, is divided into fourteen chapters and illustrated by seventeen text figures and a frontispiece. Its contents are generally interesting and well arranged, but there is recognisable throughout its pages a leaning towards the racy and sensationally attractive, as, for example, in the method of dealing with the habits of the sword-fish and the feeding process generally. The mode of treatment is mainly physiological, the consideration of function preponderating over that of structure and development. Migration and "transformation" are in turn dealt with, the latter with a commendable emphasis of the part played in Nature's operations by "substitution."

Much attention is given to the skeletal organs and especially the teeth, and the author loses no opportunity of forcing home the lesson of the tooth-scale homology. The effort, however, is somewhat weakened by the assertion that, while fish-scales are (p. 29) typically "horny plates," they are (p. 31) in "the most primitive form" bony. The statement that the bony fin supports (p. 68) have been formed by the fusion of clusters of original "hair-like" rays is equally misleading; and in dealing with the terms expressive of types of tails, the author falls into the prevailing fallacy of applying them to the fins and not to the fishes themselves. In declaring that in the typical fish the dorsal fins are two in number, the fact that there may be three dorsals is ignored, it being implied (p. 58) that the codfish has but two. And error is further evident in the assertion that the adipose fin is "without supporting structures."

The mode of description is in places none too well chosen. Such declarations as that the "beauty" of the Cestracion's teeth is "entirely an accidental feature" and that in deglutition the "touch" of the swallowed food "signals" through the closed-up gullet to the nerves, are to be deprecated in a book of this kind; while a greater regard for the facts of morphology would have been in places acceptable, as in the mode of treatment of the types of so-called external gills. The existence of these in the Teleostei is denied; but while we excuse the non-allusion to those said to occur in the loaches, we consider it strange that, on a later page, the author incidentally refers to the African fishes obtained by Budgett, in which they have been proved to be abundantly present, without mentioning them. Nor is he more fortunate with his treatment of the internal gills and respiration, for nowhere in the book are the numerical limitations of the former even stated, nor is there mention of the "breathing valves," to which attention has but recently been redrawn.

In the aforenamed and other equally important matters, which, under the scheme adopted, should have found recognition in the book, the author is not up to date, as, for example, in his declaration that nothing is known of the chimæroid development. In the organological sections of the book sufficient use is never made of extremes of modification, such, for example, as those which render clear the real differences in the composition of the gills of the bony fishes and elasmobranchs, expressed in the terms pectino- and cysto-branchiæ. Particularly is this the case with the alleged distinctions between the two chief groups into which the author would divide the fishes as a whole. He gives, for this purpose, a classification, which is neither that of the author to whom he ascribes it nor an accurate statement of Huxley's observations, upon which it is based. "Hyostylic" and "autostylic" are the terms which denote the distinctive characters of his two great "branches," but the former is wrongly construed. Neither the author of the present work nor he whom he names acknowledge the condition termed by Huxley the *amphistylic*; and the author himself does not even mention the Notidanidæ, of which, alone among living fishes, it is diagnostic. These and the Port Jackson shark (which exhibits a marvellously transitional condition of the parts in question, for which alone a distinctive term might well be introduced) are not typically hyostylic. They are lower than those fishes which are. Without recognition of them and the amphistylic state Huxley's system cannot be adequately set forth. So important is this morphologically that advantage might be gained by associating the Notidanidæ with at least the Hydodonts and Pleuracanths among fossil forms, in a distinct order, in preference to the retention of the name "Ichthyotomi" for the latter alone. In the present case, in the non-recognition of these amphistylic forms and the absence of all reference to the hyomandibular element, the essential point is lost. In the spread of scientific knowledge, the more elementary that imparted the more precise should be the diagnoses employed.

There is a closing chapter on palæichthyology, of a very cursory type.

The present book is the second which the author has contributed to the series to which it belongs. The first, on "The Story of Bird Life," was in every way a success and as a popular treatise exemplary. Comparison shows that the striking differences between the two books are due to the fact that with the first of them alone the

author's knowledge was based on a thoroughly practical acquaintance with the animals with which he dealt. While we fully admit the difficulties of the task of compilation of the second, the present work, we regret we cannot recommend it with the confidence extended to its predecessor.

THE PROBLEM OF TRUTH.

Das Wahrheitsproblem unter Kulturphilosophischem Gesichtspunkt—Eine philosophische Skizze. Von Dr. Hermann Leser. Pp. iv + 90. (Leipzig: Dürr'sche Buchhandlung, 1901.) Price 2 marks.

THE author of this work is not a "jesting Pilate." His book contains rather a thorough discussion of the problem of truth in some of its widest issues. The standpoint is essentially Kantian, but with a difference. The question raised in the "Critique of Pure Reason" was, How are pure mathematical science and pure natural science possible?—in other words, on what principles can it be maintained that the ordinary experience of man *quâ* intellectual gives him truth? Dr. Leser contends that the problem should be stated more widely in the form, How is truth in general possible, the truth of all the higher spiritual life of man, of religion, morality, art, as well as science? And it is claimed for the work before us that, as compared with Kant's, it is more concrete in treatment, that it goes nearer the heart of things, and that while including and remaining true to Kant's results it gives a more satisfactory basis for future development.

The first part deals with a deepened idea of experience, for which the author employs the term "Kulturhistorische Erfahrung." By this he appears to mean the higher spiritual experience of the race as exhibited by history in such things as institutions, codes, systems, standards of judgment. In the development of this view, naturalism is subjected to some telling criticism. Finding nothing anywhere but "bare results, finer complications of natural process," naturalism would exclude all facts which do not coincide with, or cannot be reduced to, the facts of ordinary natural science. In dealing with the institutions in which the spiritual life has found expression, naturalism pays regard only to the crystallised form, not to the spiritual potencies which have been at work. It attaches exclusive value to what is genetically original, and denies, for example, the characteristic distinction between good and bad by deriving it from the distinction between the useful and the harmful. Such a psychogenetic method can never get beyond brutal actuality to norms or standards of judgment; it is only a transcendental method (the author maintains) which can disclose the organisation of "rulers and subjects," for example, the subordination of what is first in time to what is ideally fundamental.

The latter part of the book is concerned with the problem of truth from the new standpoint thus gained. It is pointed out that Kant replaced the old objectivity (supposed to exist entirely out of relation to a subject) by transcendental-subjectivity, than which no more secure objectivity can be found. This means that truth is to be found by "turning to one's own depths"; but if it is to be depths and not shallows, to be *transcendental*-subjectivity in the right sense and not bare subjectivity in the wrong sense, we must have recourse to "Kulturhistorische Erfahrung." It is only as experience is writ thus large that the potencies at work can be discovered. One of the chief of these potencies is personality. Personality Dr. Leser opposes on the one hand to bare individualism, and on the other to the equally bare disregard of the personal factor. The great man is neither the heaven-sent hero dear to the soul of a Carlyle nor the hollow pipe through which the "Zeitgeist" pours such music as it listeth. Or, as our author puts the latter point: "The man is more than the product of his time; planting himself on the original truth which he has found within him, it is he who first makes a new height attainable."

The work is not unnecessarily stiff. At times, perhaps, a little vagueness is felt, and the technical terms, as usual, can rarely be translated by single words. But his readers will doubtless welcome another book from this careful and suggestive writer. R. G. N.

OUR BOOK SHELF.

Catalogue of the Lepidoptera Phalaenae in the British Museum. Vol. iii. "Catalogue of the Arctiadæ (Arctianæ) and Agaristidæ in the Collection of the British Museum." By Sir George F. Hampson, Bart. Pp. xix + 690. Plates xxxvi–liv. (London: Printed by Order of the Trustees, 1901.)

FOR a long time after the study of exotic butterflies began to grow popular in England, that of moths continued to be much neglected, though moths, taken as a whole, are equally beautiful and far more numerous than the butterflies. But after the pathway had been smoothed by the useful, though much abused, catalogue of Walker, the works of Moore, Butler and Druce, and especially by Kirby's "Catalogue of Lepidoptera Heterocera: Sphinges and Bombyces," published in 1892, the Trustees of the British Museum decided to issue a general descriptive catalogue of the moths of the world, which bids fair to become one of the largest and most profusely illustrated of all their publications on natural history.

The work was entrusted to Sir George F. Hampson, and three thick volumes have already been issued. According to the table of families in vol. i. the author admits fifty-two, which, deducting seven for the butterflies, leaves forty-five for the moths, of which only the first three are monographed in the portion of the work already published, so that little more than the fringe of the subject has yet been touched. Of course some of these families only include a few species; but, on the other hand, there are several very much more extensive than the Arctiadæ, which alone fill up the greater part of vols. ii. and iii. The plates are published separately, and can be bought separately, a useful arrangement which will enable students who require an additional copy of the book for working purposes to purchase it without the additional and unnecessary cost of a duplicate set of coloured plates. In addition to these coloured plates, drawn by Mr. Horace Knight and chromolithographed by West, Newman and Co., the book is further illustrated by text-illustrations of types of genera, showing both the pattern and the most important generic details, and of these compound figures there are no less than 294 in vol. iii., in which 946 Arctianæ and 225 Agaristidæ are described, of which a considerable number are new species. At the end of the volume is a short list of species which the author has not been able to identify from the published descriptions. Should further information respecting these be forthcoming, we presume that

these, and any other casual omissions, will ultimately be dealt with in an appendix.

The next family to be monographed, if the author continues to follow the arrangement prefixed to his first volume, will be the extensive family of Noctuidæ, which alone may be expected to occupy several volumes.

To the technical portion of the book we can scarcely refer here in detail. It is a work that appeals mainly to specialists, and only specialists will be able to appreciate the time and labour involved in its production at their full value.

Psychology Normal ana Morbid. By C. A. Mercier, M.B. Pp. xvi+578. (London: Swan Sonnenschein and Co., Ltd., 1901.) Price 15*s*.

MR. MERCIER'S "morbid" psychology is, as one would naturally expect, the best part of his book, and almost as good is the general discussion of the questions raised by pleasure-pain and by emotion. The author dissents from Prof. James's "back-wave" theory of emotion on much the same grounds which have led to its rejection by Stout and other contemporary psychologists, and, like Stout, rightly insists that the dependence of emotion upon an object beneficial or injurious to the organism must be the starting-point of any theory of its nature. An interesting feature of the discussion of pleasure-pain is the writer's belief that there are no reproduced ideas of pleasure and pain. The present reviewer is inclined to agree with him, but the question is a difficult one. In his general theorising Mr. Mercier is far too ready to accept associationist views which are virtually dead in the scientific psychology of to-day. This is specially true of his account of perception, which is identical with Spencer's, but quite at variance with the doctrine (which pathological cases as well as the study of animals seem to demand) that "ideas" are subsequent to precepts.

The weakest part of the book is the long section on logic, which is also, strictly speaking, irrelevant in a treatise on psychology. The axiom formulated on p. 86 would justify the inference, "Solomon is the son of David, and David the son of Jesse, therefore Solomon is the son of Jesse." The furious attack upon the mathematical doctrine of probability also rests largely upon the pure misconception that the statement of chances is put forward by mathematicians as a measure of the actual strength of our belief. A. E. T.

A Record of the Progress of the Zoological Society of London during the Nineteenth Century. Edited by the Secretary. Pp. 248. (London: Clowes and Sons, Ltd., 1901.)

UNDER the auspices of a committee consisting of Mr. Sclater, Dr. Smith Woodward, Prof. Howes and Mr. Beddard, Mr. Scherren has prepared an excellent account of the principal doings of the Zoological Society since its foundation in 1826. The statements made are partly financial and partly relate to the number of the public who have availed themselves of the opportunity of entering the gardens, as well as to the papers read before the Society and to the lectures delivered in the gardens. It is curious to note the gradual growth of the popularity of the Zoological Gardens as a place of resort, a growth which is not altogether *pari passu* with the increasing population of the country. Thus from 1872 to the present day the number of visitors has always exceeded 600,000, and in two notable years, viz. 1876, when His Majesty the King, then Prince of Wales, deposited the animals brought back by him from India, and again in 1882, the year of the "Jumbo-mania," exceeded the usual maximum by a hundred or two hundred thousand. From 1864 to 1871 the numbers were 500,000 and upward, while in earlier years the average number was not more than 300,000 to 400,000, with the exception of the phenomenal years 1851 and 1863, when the admissions rose to more than 600,000. The earliest year in which these numbers are recorded is 1829, when only 98,605 persons visited the gardens. The numbers then rose and again fell during the 'forties. During these seventy-four years there have been eight presidents, seven secretaries and three vice-secretaries. The late Earl of Derby and the late Sir William Flower held their office of president for the longest period, viz. twenty years, and next in order of tenure come the Prince Consort and the Marquess of Tweeddale, who occupied the chair for ten years each. This volume contains also a list of the present Fellows of the Society and the charter and bye-laws.

Leitfaden der Landschafts-Photographie. By Fritz Loescher. Pp. v + 162. (Berlin: Gustav Schmidt, 1901.) Price Mk. 4·50.

WITH so many books in the English language on the subject of landscape photography, the amateur or professional may not think it worth while to read any new German work on the subject. This, however, should not be the case, for from such a volume as the one under notice it is possible, not only to obtain useful hints familiar on the Continent and unknown here, but at the same time to acquire facility in reading a foreign language.

The reader will certainly not be disappointed when he spends a few hours in becoming acquainted with what Herr Loescher has to say in these 162 pages, for although the author goes, for the main part, over familiar ground, yet here and there a subject or object is seen from a new point of view.

The book is logically divided into three parts, namely, before the exposure, the exposure and after the exposure. The first deals with the apparatus generally employed in tripod and hand-camera photography, touching on the use and determination of the speed of shutters, perspective as produced by the objective, various kinds of and uses for photographic plates, and useful hints as regards packing, &c., for those who make long tours with cameras.

The second portion is restricted to the choice of the subject and the best way to photograph it, the author here giving some valuable suggestions on the consideration of distance, foreground, trees, sky, illumination and minor accessories to the picture. In the third and last portion of the book the treatment and after treatment of the exposed plate are described, the latter including all such manipulations as intensifying, retouching, copying, mounting, framing, enlarging and lantern-slide making.

Accompanying the text are twenty-four autotype reproductions from the author's own negatives.

Inductive Sociology. By F. H. Giddings, Ph.D., LL.D., Professor in Columbia University, New York. Pp. xviii+302. (London: Macmillan and Co., Ltd., 1901.) Price 8*s*. 6*d*. net.

THE object of this book, in the words of the author, is "to present a scheme of inductive method, a somewhat detailed analysis and classification of social facts, and a tentative formulation of the more obvious laws of social activity." It is not in any way a mere discussion of the possibilities of census taking, but an attempt to formulate a general scheme for the statistical, or quasi-statistical, description of a nation or "society," using materials from every available source. Thus the description covers the features of the area inhabited, the nature and sources of the food supply, the density, multiplication, migration, &c., of the population, and its racial composition; the political activity, cooperation for social ends, and general organisation of the society; its social security and administration of justice; wealth and its distribution; education; vitality and morality. The work is prefaced by four introductory chapters on the study of sociology and the inductive methods to be used.

It is gratifying to find a writer on sociology acquainted with modern mathematical methods of statistics, and one who clearly recognises the value of such methods, but the definitions given in Chapter iii. of the introduction require some rewording. The word "number" on p. 21 is apparently used in the sense of "magnitude of the variable" instead of in the more natural sense of "frequency," but even in this sense it would not be correct to define the median as "the number midway between the lowest and highest"; it is correctly defined by the statement that magnitudes greater and less than the median occur with equal frequency, so that the median will not in general coincide with the middle of the observed range. Again, it is hardly correct to speak of a measure of variation as the "*mode* of the deviation"; mode is used in the sense of "most frequent value," and the most frequent deviations in the case of symmetrical distributions will be those approximating to zero. The term "standard deviation" was defined by Prof. Pearson, its introducer, in the sense of root-mean-square deviation, and it is apt to lead to misunderstanding if used in a vague sense, as in the text. The section on the "law of sympathy," pp. 108–110, would also be the better for, at least, some additional explanation; it is from its curtness almost incomprehensible as it stands, and some of the symbols used appear to be only defined in the appendix.

The book is suggestive of many possible lines of research by means of indirect statistical index-numbers, but we cannot help feeling that the author has tried to cover ground too wide for a single volume. The work as it stands is so abstract that it is almost impossible to estimate the practical value of the author's ideas, and such abstractness alienates the sympathy of the statistician. A much more liberal discussion of examples in the text would be both valuable and refreshing.

G. U. Y.

Optical Lanterns and Accessories. Edited by Paul N. Hasluck. Pp. 160. (London: Cassell and Co., Ltd., 1901.)

THIS handbook forms one of a series of practical manuals, and it brings together the more important and useful information in relation to the construction and management of optical lanterns. For the main part the editor has utilised material which has been published from time to time in the weekly journal *Work*, and has coordinated it in such a form that it will be found very serviceable to those who have much to do with lanterns. There are also chapters on the making of ordinary photographic, coloured and mechanical lantern slides, and some useful hints regarding the management of kinematographs. The book is well illustrated and should be found very handy.

Plane Geometrical Drawing, including numerous Exercises and Army Examination Papers, with Solutions. By R. C. Fawdry, M.A. Pp. xi+185. (London: E. and F. N. Spon, Ltd., 1901.) Price 6*s*. net.

THIS is a work of quite an elementary character, and very well suited to candidates for admission to Woolwich and Sandhurst. A good feature of the book is that it either gives a proof for each construction or refers to the particular proposition of Euclid on which the construction is founded. In addition to constructions relating to right lines, triangles, polygons and circles, there is a short chapter on the ellipse, which, in a second edition, might very well include a treatment of the parabola, inasmuch as the parabola is at once one of the simplest and the most useful of curves in the applications of mathematics. There are two good chapters on the use and construction of scales, and the book concludes with several specimens of papers set in the subject at the Woolwich and Sandhurst examinations, together with the solutions of the questions.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The "Chestnuts" of the Horse.

THESE structures are well known and have been variously interpreted. But I believe that a suggestion as to their nature which I shall now put forward has not yet been made. Some months since I called attention in this Journal (vol. lxii. p. 523) to the general prevalence among mammals that use their fore limbs as grasping or climbing organs—in fact, in all other ways excepting as mere organs of progression—of a tuft of long hairs upon the wrist. I have since that time examined a large number of mammals, and find these vibrissæ in a considerable number of genera belonging to the orders Marsupialia, Rodentia, Carnivora, Lemuroidea (in which latter group the vibrissæ in question were first noted by Mr. Bland Sutton). They are absent from the Ungulata with the exception of hyrax, an admittedly ancient type of ungulate. Usually, but not always, a stout branch of the radial nerve of short extent ends in this patch of integument which bears the vibrissæ. The vibrissæ are quite similar to those found upon the head of the same mammals, for example the "whiskers" of the cat. The general occurrence of this carpal tactile (?) organ makes it, at least on *a priori* grounds, reasonable to suppose that traces might be met with in the ungulates, other than hyrax, where it unquestionably exists. There might not at first sight appear to be much in common between the callous pad, such as is the "chestnut" of the horses and asses, and this tuft of vibrissæ; but the conditions which I found to obtain in an armadillo (*Dasypus villosus*) suggested the comparison. In that animal the carpal tuft of vibrissæ is present; but instead of being a closely compacted tuft of about six hairs, as is usually the case, the hairs in the armadillo are not much larger than those of the skin generally, and are spread over a patch of integument of about half an inch in length and are more numerous. The patch of skin which bears them is thickened. If this were to proceed further the more strongly cornified epidermis would cease to bear vibrissæ, which would be, so to speak, driven into a corner beyond the specially thickened tract of skin. This stage, moreover, is not hypothetical; for in *Lemur catta* precisely this state of affairs exists, *i.e.*, a callous tract of skin close to which is a tuft of vibrissæ. If the latter were lost we should have the "chestnut" of the horse. The chestnuts on the fore feet, be it observed, occupy the right position, a little above the wrist.

FRANK E. BEDDARD.

Frost Patterns.

AS I was responsible for opening the discussion in these columns in 1892 and as I am able to confirm Dr. Catherine Raisin's observation as to the recent recurrence of the phenomenon on December 15, I am glad of the present opportunity of sending a few lines on the same subject in order to rectify an omission. In 1873 Prof. Joseph Henry, of the Smithsonian Institution, Washington, forwarded to Prof. Tyndall on behalf of Prof. Lockett, of the Louisiana State University, a beautiful photograph of "plumes produced by the crystallisation of water," the said pattern having been formed in the coloured sediment in the bottom of a basin in which the water had frozen during the night. This photograph is reproduced as a plate in Tyndall's "Lectures on Light" (I have only the second edition, 1875). It escaped my notice during the correspondence in 1892 or I should certainly have called attention to it.

R. MELDOLA.

Roads and National Welfare.

IN NATURE of December 19, 1901 (p. 149) is given a criticism of a work, in which some essential points in the making and maintenance of roads are strongly insisted on. At p. 156 of the same number there appears an excellent commentary on Mr. Balfour's speech to the students of the Goldsmiths' Institute at New Cross on December 12. With your comments I am in thorough sympathy, and would beg leave to point out that the two subjects are far more closely connected than might at first appear. Excellence and superiority

in manufactures and commerce depends on very many elements, as you know, one of the most important of which is the "item" "carriage or transport." British superiority in many manufactures and markets has depended, and will henceforth largely depend, on that one item principally (take the case of iron ores), and to maintain superiority it must receive in the immediate future more careful attention and scientific treatment. Roads in their different forms enter largely as factors into the general question of "transport," and if trade superiority is to be maintained they must be looked after and treated, all over these countries, in a more scientific and skilled manner than that now prevalent in the United Kingdom. For that end there must be attained, as soon as possible, uniformity of make, treatment and control, and the highest efficiency as regards care and maintenance, and to ensure these results they should be placed under the charge of a body of trained engineers, such as those of the "ponts et chaussées" of France. The question to a certain extent resembles that of the currency of the realm, and as there is a perfectly uniform coinage for every part of it, so should the make and use of the roads be of one standard all over the kingdom, in the best interests of all who travel or convey goods. The Board of Trade controls the railways, why not a Board or Department for the roads? and thus obviate the many absurd and scandalous practices which exist and are allowed to prevail, to the great discomfort and loss of the community. Allow me to give my experience of what is taking place in the township of Pembroke (Dublin). The road "metal" mostly in use is simply the coarser riddlings from the drift gravel so abundantly and cheaply worked in the neighbourhood of the Town Hall. The stones, perfectly rounded, incapable of taking bond and largely composed of entirely rotten elements, are loosely thrown here and there, where prominent holes appear. Mr. Beete Jukes, the former head of the Geological Survey of Ireland, remarked when he saw the material used, that boiled potatoes might as well be employed, and the rapid wear fully bears out the correctness of this judgment, and hence a large staff of scavengers and carts, discomfort for all classes of road-users, and steady increase of rates. In a southern county I have seen the road surface worn into the form of the section of an inverted arch, and was informed by a competent authority that the county surveyor, a Whitworth scholar, secured the place as the result of a Civil Service examination, the pay being about 800*l.* per annum, and thus secured, proceeded to develop a private practice as civil engineer, leaving the roads to attend to themselves. Many other examples of this nature might be given. As to the importance of good roads from a military point of view, it should be unnecessary for me to refer to it. I see from time to time the Dublin garrison companies and battalions out on marching exercise and notice the draggled appearance in which the men come home when the weather is in any way moist or rainy, and reasonably associate this condition with the bad state of the roads about Dublin. The Romans certainly knew better on this branch of military engineering, and might still be copied. As for agriculture, the Americans have gone thoroughly and systematically into the question, and are taking effective measures to put their road systems into a proper working state, and to have them kept up to it. I trust, Sir, that you will excuse these rather extended observations and that you will see your way to urging the pressing importance of a uniform and general system of road making and maintenance for the kingdom on the grounds of high State utility, commercial importance and agricultural necessity.

J. P. O'REILLY.

Dublin, December 28, 1901.

Preoccupied Names in Zoology.

THIS afternoon I spent a lttle more than half an hour over the "Zoological Record" for 1899, looking for preoccupied generic names proposed in that year. The result was as follows:—

Baris, Loos, for a plathelminth in the alimentary canal of Chelonia is untenable because of Baris, Germ., a genus of beetles.

Astia, Loos, for a worm in gut of Tetrodon; *nec* Astia, Koch, an arachnid.

Brotella, Roverto, new name for Acrostoma, which was preoccupied; *nec* Brotella, Kaup, in fishes.

Cumopsis, Roverto, new name for Cuma, Humph., preoccupied; *nec* Cumopsis, Sars, Crustacea.

Eichwaldia, Smitt, new subgenus of Gobius; *nec* Eichwaldia, Bill., Mollusca.

Goniopsis, Melichar, new genus of Fulgoridæ; *nec* Goniopsis, Haan, Crustacea.

Halticella, Jacoby, new genus of beetles; *nec* Halticella, Spinola, Hymenoptera.

Xenus, Péringuey, new genus of beetles; *nec* Xenus, Kaup, in birds.

I left off with the feeling that by taking time such instances could be multiplied almost indefinitely!

This is a condition of affairs which is becoming intolerable. None of the authors of the above names had even taken the trouble to consult the "Nomenclator Zoologicus." Such names become current for a number of years, until someone happens to discover that they have been used before. The result is an inconvenient though necessary change and a useless synonym. Sometimes authors will not even correct these errors of nomenclature when their attention is directed to them, and if they do propose a substitute there is no telling whether it will be valid.

Would it be practicable for some representative body, such, for instance, as the staff of contributors to the "Zoological Record," to examine every new generic name proposed and issue from time to time a list of substitutes for names found untenable? Or, if it were preferred, the author in each case could be asked to propose a substitute, and then all the substituted names could be given in an appendix to the "Zoological Record." Whatever is done, it seems necessary that these errors should be promptly corrected, and equally plain that this cannot be left to the unaided intelligence of authors.

East Las Vegas, New Mexico, U.S.A., December 16, 1901.

A Luminous Centipede.

MR. R. I. POCOCK, to whom I sent the subjoined extract from notes made by me on June 5, 1897, has suggested that the observation would be of interest to readers of NATURE. He remarks: "The two new facts you have observed—namely, the defensive purpose of the substance and its irritating properties—are, I think, sufficiently important to put upon record." The notes are as follows:—

"Under the entrance gate, in the gravel, I saw a light of a brilliant greenish-bluish tint; it moved forward, leaving behind a trail of light which, gradually separating, became a scattered mass of brilliant points. The leading light had the form of a living, curving thread. A lighted match soon showed what the scattered points of light in its trail were, a dozen or so of red ants pursuing the Geophilus; one was clinging to it, each ant shone like a spark in the gravel, the centipede had discharged its fluid over them. I picked up the centipede and dropped it into a tumbler, where it splashed out a mass of light. Hurriedly placing my hand over the tumbler to prevent the insect from escaping, I felt suddenly a strange prickly sensation such as is caused by a slight contact with electricity, so that I hastily removed my hand, calling to a friend who, placing her hand over the tumbler, felt the same thing.

"I lit another match and watched the Geophilus writhe the light out of its body in blue-green flashes. It soon ceased to shine, having probably exhausted all the luminosity on its enemies.

"Defence seems certainly to be one of the uses of this secretion, attributed by some authors merely to purposes of attraction.

The New Planetoid.

THE note on Prof. Pickering's announcement of the discovery of a new planetoid moving in a very elliptic orbit, in the Astronomical Column of your issue of December 19, 1901, was read by me with much interest.

I should, however, like to point out that the orbit of the new planetoid is not the most elliptic yet known, that place being held, I believe, by Æthra (132), for which ϕ amounts to 22° 32′ (Watson's orbit), while for the new planetoid ϕ is 22° 8′.

Andromache (175) might also be included among those for which ϕ exceeds 20°, in addition to the two named in the note, Eva and Istria, its excentricity being 0·348 (Watson).

Prospect Road, Barrow-in-Furness.

SCIENTIFIC BALLOONING.

THE exploration of the upper air has become increasingly attractive as a branch of meteorological inquiry, and the soundings of the ocean of air, to use Mr. Rotch's expression, may be held to include observations at high-level stations, records obtained from instruments carried by kites or unmanned balloons, as well as observations made by travellers in free balloons. Of these the last mentioned offer most attractions for the adventurous, and they form an essential part of scientific inquiry, because eye observations can be taken of clouds and other atmospheric phenomena from a point of view not otherwise attainable, and experiments that throw light upon the working of various instruments can be carried out under conditions which cannot be exactly imitated on the earth's surface. For meteorological purposes the usefulness of a free balloon is, however, to a certain extent limited by the fact that the balloon is an aërostat; it is carried with the stratum of air supporting it and the only motion relative to the atmosphere is a vertical one. Wind as understood at the surface is therefore beyond the scope of observation of the balloonist, and all meteorological observations that are dependent upon the motion of air are not primarily suitable for the car of a balloon, where the air is calm and still even in a rapidly moving atmosphere.

The traveller can in clear weather estimate the rate at which he is borne along by noting the places over which he passes, and he can obtain permanent records of his voyages by photographs taken from his car, which suggest a curious reminiscence of old-fashioned maps. A photographic camera is indeed the first and most natural item in the equipment of a balloonist, whether the aim of his voyage be scientific inquiry or merely adventure. One of the most novel and successful departments of the Paris exhibition of 1900 was the aëronautical section, which gave full opportunity for the display of the powers of aërial navigation. During the exhibition fourteen competitions were held, in which a hundred and fifty-six ascents were made. The competitions were of four kinds; for altitude, for duration of voyage, for distance and for descent at a specified spot. The competitors were exclusively French; the greatest height reached was 8417 metres, the longest voyage in time lasted 35·45 hours and covered also the longest distance, namely, 1925 kilometres; the nearest approach to a given point was within 400 metres, after a voyage of 32 kilometres. Of the 156 voyages, 137 were completed within France, ten extended to Germany, three to Belgium and three to Holland, while three were not terminated until the Russian frontier was passed. It is satisfactory to note that all were conducted without accident either to aëronaut or spectator. Among the many interesting photographs obtained during these expeditions is one of the neighbourhood of the Panthéon, Paris, taken from a height of 500 metres and reproduced (Fig. 1) from an article by Commandant Renard in the *Bulletin* of the Société d'Encouragement pour l'Industrie Nationale. For the purpose of comparison, a photograph of Berlin from a height of 2000 metres, taken in 1893 on one of the voyages of the ill-fated balloon *Humboldt*, is also reproduced (Fig. 2). It shows the Belle Alliance Platz in the centre, but the scale is evidently very small. A slightly larger view (Fig. 3) of the central portion, taken on another occasion, is here reproduced from the frontispiece of Prof. Assmann's memoir, "Die Modernen Methoden zur Erforschung der Atmosphäre mittels des Luft-ballons und Drachen," which appeared in the March and April numbers of *Himmel und Erde* last year.

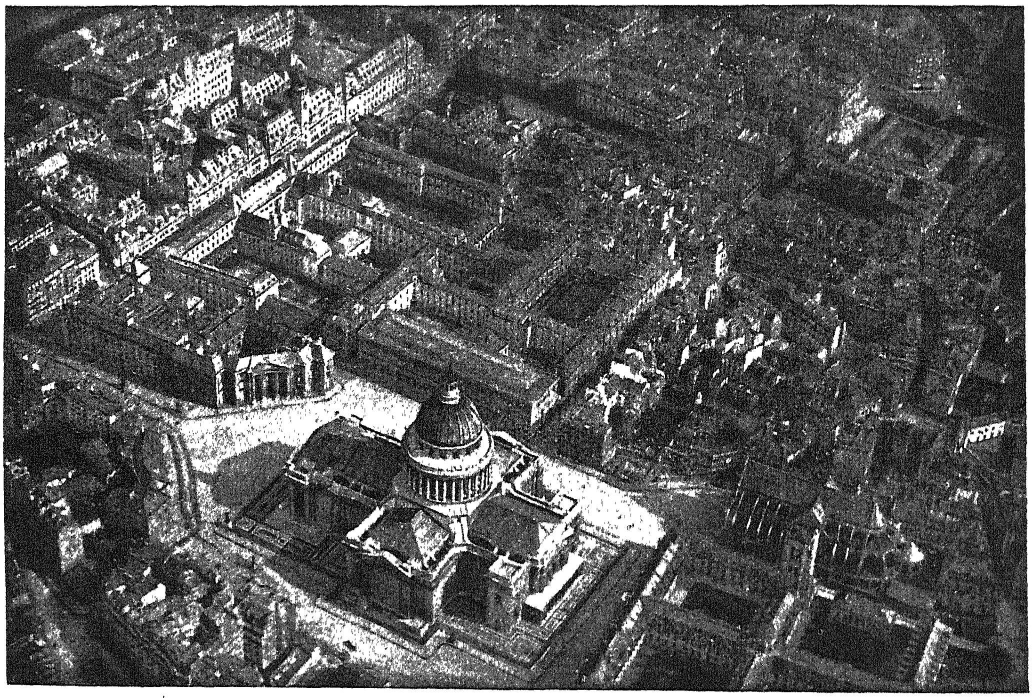

FIG. 1.—Neighbourhood of the Panthéon, Paris, photographed from an altitude of 500 metres.

Among the best known establishments for exploring the upper air are those of M. Teisserenc de Bort at Trappes for "ballon sondes" and kites and Mr. Lawrence Rotch for kites at Blue Hill, Massachusetts; but the general use of balloons for scientific purposes has been carried out most effectively at Berlin. By means of funds supplied

by the Emperor William, a very complete establishment for the exploration of the upper air has been installed there. The first balloon acquired was the *Humboldt*, which made its first voyage on March 1, 1893. It was fired by

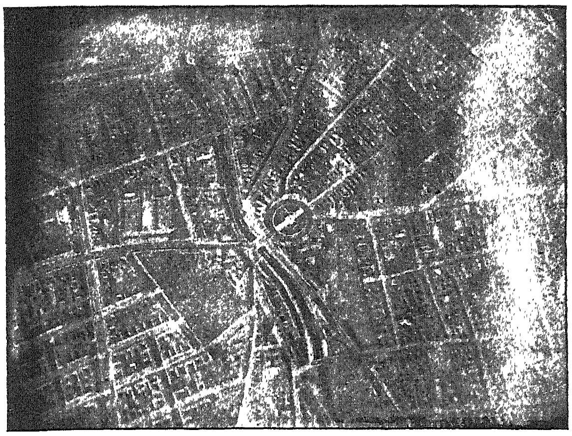

FIG. 2.—South-west Berlin (Belle Alliance Platz), photographed from an altitude of 2000 metres.

an electric spark and destroyed on landing after its sixth voyage. Through the Emperor's generosity it was replaced by the *Phönix*. Prof. Assmann, in the work already referred to, gives some particulars of the arrangements and results, but the subject is more fully dealt with in a work consisting of three handsome volumes published last autumn and entitled "Wissenschaftliche Luftfahrten ausgeführt vom Deutschen Verein zur Förderung der Luftschiffahrt in Berlin" (Braunschweig: F. Vieweg und Sohn). This contains the account of seventy-five voyages and a number of flights of unmanned balloons, together with the material collected in the course of the expeditions, maps of the regions traversed and a volume of results. The meteorological interest of these voyages is very great, but the work is too elaborate for brief summary. A single example may give some idea of the possibilities of investigation of this kind. On July 6, 1894, the *Phönix* started from Berlin at 6.32 p.m. and travelled north-west to Jutland in nineteen hours; the unmanned balloon *Cirrus* was started at the same time from the same place and was carried by an upper current to Bosnia.

The primary meteorological question to be determined by balloon ascents is the rate of variation of temperature with height. For some time after Glaisher's celebrated voyage of 1862, which concluded his balloon work, the matter was regarded as settled. The Berlin work has reopened it on the ground that the thermometers used by Glaisher were not sufficiently ventilated or screened from radiation. Glaisher was aware of the necessity for precautions, although he discarded special apparatus for ventilation, and his immense experience in the use of thermometers might enable him to obtain results, as, for example, with Daniell's hygrometer, where others of less skill and experience would fail. In the balloon investigations by Berson, Assmann's ventilation thermometer, with special mounting to avoid the car's interference, was used, and every precaution was taken to make the circumstances otherwise comparable with those under which Glaisher made his memorable ascent from the Crystal Palace. M. Berson carried these precautions even to the length of making an ascent from the Crystal Palace itself on September 15, 1898, while a simultaneous ascent was made at Berlin, to make sure that the observed differences were not due to climatic differences between the air over Germany and over England. The day was remarkably hot in England, the temperature being 10° C. above that of Berlin, but the zero isotherm was found within a few hundred metres of 6000 metres at each station. Further trial was made by reproducing Glaisher's arrangement from his description and comparing its readings with the Berlin arrangements. The results were only accepted as conclusive after careful consideration of all the measurements of temperature obtained from the numerous flights of manned and unmanned balloons. In the end Berson was satisfied that the difference of the observations was to be laid to the account of instrumental errors in Glaisher's observations.

The comparison of Glaisher's and Berson's results for the rate of fall of temperature with height, as given by Assmann, is as follows:—

Height in metres.	Rate of fall in Centigrade degrees per thousand metres.	
	Glaisher.	Berson.
0–1000	7·5	5·0
1000–2000	6·5	5·0
2000–3000	5·0	5·4
3000–4000	4·2	5·3
4000–5000	3·8	6·4
5000–6000	3·2	6·9
6000–7000	3·0	6·6
7000–8000	2·0	7·0
8000–9000	1·8	9·0

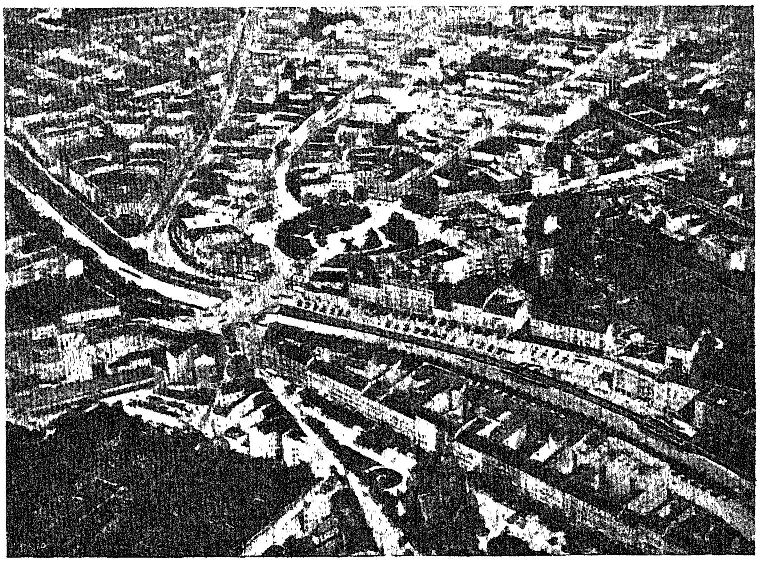

FIG. 3.—Neighbourhood of the Belle Alliance Platz, Berlin, photographed from a balloon.

It will be noticed that whereas Glaisher's observations lead to the conclusion that a constant temperature is indicated at no very great height, Berson's numbers show increasing rate of fall with height, so that the difference

in the results is one of fundamental importance. Berson's numbers clearly do not go to the end of the matter, for with a little play of the imagination in the region of extrapolation, his results bring absolute zero within sight at the very moderate height of some thirty miles, whereas $-68°$ C. is the lowest temperature recorded in the flight of the unmanned balloon *Cirrus* from Berlin, which is reported to have reached a height of 18,000 metres. This, by a curious coincidence, is identical with the lowest temperature recorded at the earth's surface. It was registered at Werchojansk, in Siberia, on January 15, 1885; a still lower temperature, $-70°$ C., is given in the *Meteorologische Zeitschrift* for June as registered by the apparatus of an unmanned balloon started from Vienna on January 10 of last year. Kite observations also afford information as to the rate of fall of temperature under varied meteorological conditions. But the height which they can attain does not give them a final voice in the determination of the question of the lowest limit of atmospheric temperature.

Another quantity for the determination of which balloon observations are specially appropriate is the constant of solar radiation, but the results are not yet final and the subject is too wide for this occasion.

It would be a matter for congratulation if Glaisher's exploration of the upper air could be continued by his own countrymen. Investigations have, indeed, been made recently by the Rev. J. M. Bacon, and, under the auspices of the Aëro Club, by the Hon. C. S. Rolls. But for the use of balloons on any considerable scale these islands are not very suitable. It will hardly yet be forgotten that some years ago an attempt to pursue scientific investigation in this manner resulted in the loss of a valuable life. Work with kites even is not without its dangers, but it is satisfactory to note that the Royal Meteorological Society has taken up this mode of investigating the upper atmosphere, and has not only moved the British Association to devote a sum of money for the purpose, but has secured the active interest of the president of the Society, Mr. W. H. Dines, in the undertaking. The British Isles occupy such an exceptional position with regard to the passage of weather changes from the Atlantic Ocean that the results of a properly directed inquiry of this character can scarcely fail to throw important light on many meteorological questions.

One of the results of the Congress of Meteorologists at Paris in 1900 was an international arrangement for the simultaneous exploration of the upper air in the various countries of Europe by means of unmanned balloons carrying self-recording instruments. An ascent was to be made on a fixed day in the first week of each month. Prof. Hergesell, of Strassburg, chairman of the Aëronautical Committee of the International Conference, undertook the collection and the working out of the results. The ascents have been regularly carried out and brief reports have appeared in the *Meteorologische Zeitschrift*. In this country Mr. P. Y. Alexander, of Bath, has carried out ascents of unmanned balloons on some of the appointed days, and has made provision for observations in manned balloons by Mr. Spencer. With the balloon observations are associated observations of clouds. We have no system of systematic measurement of cloud movements, but in connection with the balloon ascents the following observatories have furnished eye observations of the form and motion of clouds on the days of the ascents and the preceding and following days, viz. Greenwich, Kew, Oxford, Bidston, Stonyhurst, Rousden, Falmouth, Glasgow, Aberdeen and Valencia. The returns have been sent to the Meteorological Office to be forwarded to Prof. Hergesell. The details of the ascents of November 8, 1900 (the tenth of the whole series of international ascents) have already been published, and they show in a very effective manner the initial increase of temperature with height in the region of the anticyclone which covered the continental stations, Paris, Strassburg, Berlin, Vienna and St. Petersburg, at which ascents took place. Inversions of temperature are also very marked in the discussion of the Vienna observations for the ascent of January 10 by J. Valentin in the *Meteorologische Zeitschrift* for June.

For meteorological purposes balloons will be much more serviceable when the means for converting them from aërostats into airships are perfected. It is fifteen years since Commandant Renard, who with his brother has been so active in all that concerns military ballooning in France, published his lecture, "Sur la Navigation Aérienne," before the Société de Secours des Amis des Sciences, in which he lays down with true French clearness the dynamical conditions for the airship as distinguished from the aërostat. The publication is illustrated with a picture of an airship corresponding very closely with those of the airship of M. Santos Dumont that have attracted so much public attention within the last few months. At present airships are at best fair-weather vessels, and fair weather is a dull subject for meteorologists.

W. N. SHAW.

GUN-SIGHTS FOR LARGE AND SMALL ORDNANCE.

UP to quite recent times but little has been done by those interested in gunnery to improve in a really practical way the method of aiming either a rifle or gun. The usual method of aiming is much the same as that employed long ago in using the mediæval crossbow. The object aimed at, the fore-sight and the back-sight, are brought into line by the eye of the marksman, always with this defect, viz., that the eye is out of focus with respect to two of the points mentioned when focussed on the third. We know well that, if we fix our attention on a distant object, our eye will automatically focus itself on that distant object; and only an indistinct image of the foresight will be present. Again, should we focus the eye on the fore-sight, then the object aimed at will not be clearly seen. This is also true in an accentuated manner with respect to the back-sight, since it is nearer to the eye than the fore-sight. The operation of thus aiming, even in the best circumstances of light, is obviously unsatisfactory.

The gun-sight problem has been attacked by several leading experimentalists, and in the majority of cases some apparatus in which lenses are employed has been used. An early form of optical gun-sight consisted of a small telescope attached to the gun, the telescope being furnished with an eye-piece and cross-lines or webs, similar to those used in the surveyor's level or theodolite. This telescope is attached to the rifle by a joint at one end, the other end being raised or depressed to suit the range by means of a milled headed micrometer screw. The telescope-sight has been applied to field and other guns, and to it has been added an inclinometer, so that an angle inclination either above or below the horizontal line can be given to the gun.

Objections have been raised to the telescope-sight, and it has been urged that the field is limited, so that it is not easy to "pick up" the object to be hit, and that the object appears to be moving with a speed greater than its real one, also that when heavy charges of gunpowder are used, and the recoil is considerable, there is a risk of the eye of the marksman being injured by the cap of the eye-piece when it is driven back, and also that the adjustment of the telescope may be thrown out, by the concussion on firing the piece. With respect to the first objection, in the case of a man with short sight, the telescope-sight is of great use since it enables him to see the object as clearly as a man with normal vision. When the telescopic method is used for laying field guns, the

sight is placed in a geometric bracket for aiming and removed immediately before the gun is fired, as otherwise it would be injured by concussion.

The gun-sight invented by Sir Howard Grubb, F.R.S., is free from imperfections inherent in the old form of telescope-sights used on rifles. The new instrument is called by him the "Collimating-telescope Gun-sight," and a paper on the subject in the *Transactions* of the Royal Dublin Society (March 20, 1901) at once shows what considerations led up to the invention of the new form of gun-sight. In it the inventor pictures an ideal sighting arrangement thus:—He imagines a ring or cross to be carried on a very long, weightless and rigid rod forming a prolongation of the gun-barrel, so that the ring or cross would always be situated in the prolongation of the axis of the gun, and each shot, if the trajectory were quite flat, would pass through the ring. The inventor goes on to show that such an ideal rod might be realised by using a fine beam of light, which might be projected on to the object and indicate the direction of the axis of the gun. This end is in practice obtained by projecting a "virtual" image upon the object on which the gun is aimed. By means of the gun-sight now to be described a "virtual" image of a small bright cross or circle is projected on to the object aimed at. The earliest form

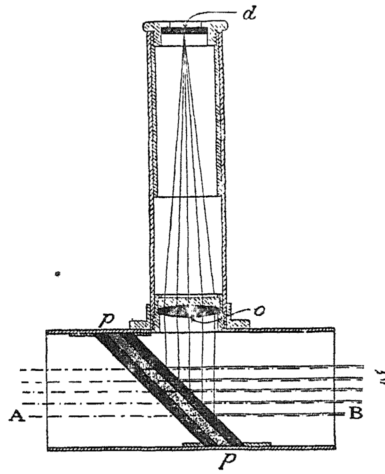

FIG. 1.

in which the gun-sight was made is shown in Fig. 1, in which the object aimed at is viewed through a piece of tube of square section AB, open at each end, a piece of parallel glass, *pp*, being fixed at an angle of 45° to the axis of the tube. In another tube at right angles to the former a diaphragm *d* is fixed, made of glass coated with an opaque substance, through which fine lines are scratched in the pattern of a cross or star or circle. *o* is an achromatic lens, and the distance between the cross and the lens equals the principal focus of the lens; so that rays of light passing through the cross, on reaching the lens, are by it made parallel, they are then reflected by the plates *pp* as parallel rays to the observer's eye, and the observer sees a "virtual" image of the cross coinciding with the object aimed at, and apparently at the same distance as the object. This optical device causes the cross to be seen sharply defined, with the same focussing of the eye required for viewing the distant object, and all straining of the eye, as is the case in the old system, vanishes; also there is no parallax, and therefore the eye need not be kept in one position. This "virtual" image of the cross, forms a fore-sight projected to a long distance in front of the rifle, as if it were carried upon an invisible, imponderable and inflexible prolongation of the barrel. This form of apparatus not being of convenient shape for practical use, the gun-sight eventually assumed the form shown in Fig. 2, in which *d* is the cross, which is reflected by the mirror C, on to a curved glass surface *rr*, coated with a very thin layer of galena, the ray is reflected as a parallel beam to the eye, and at the same time the

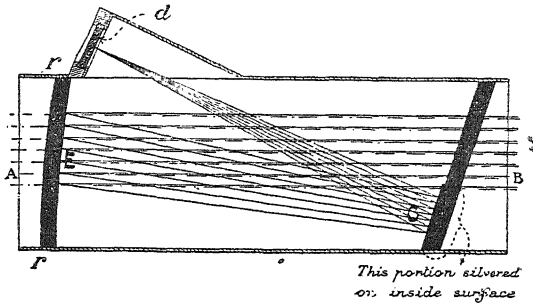

FIG. 2.

object is seen through the coated surface. The radius of curvature of *rr* equals twice the distances *d*C and CE. When the eye is placed anywhere near the axis of the gun-sight the bright cross is seen superposed on the object, and the usual effort required in the attempt to focus two objects not at the same distance is entirely avoided. The photograph (Fig. 3), taken by a camera

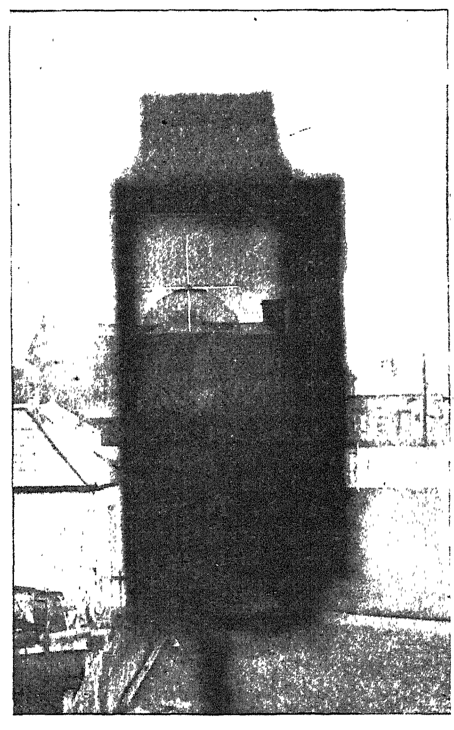

FIG. 3.

placed behind the gun-sight and focussed on the dome of a building, shows how perfectly the cross coincides with the object, both the object and cross being in perfect focus.

The gun-sight is mounted on a graduated metal arc attached to the rifle, by means of which it is adjusted for various ranges. The sight may be used either with or without a telescope or monocular, since the same focus

suits both the object and the image of the cross; also by cutting divided scales on the diaphragm glass, useful estimates may be made of both distance and windage.

In an experiment made on a gun-sight, kindly lent to the writer of this article by Sir Howard Grubb, good shooting was made on a white target when it was dusk, and an ordinary fore-sight could not be seen, by illuminating the cross, by a minute reflected side-light, entirely shielded from view from the locality of the target. This form of gun-sight could thus be used, in certain circumstances, long after the ordinary fore-sight had become invisible.

A very small diminution of light coming from the object is produced by the deposit of galena on the mirror, but it is so minute, that it practically causes no inconvenience to the marksman when aiming a rifle at a distant object.

NOTES.

PROF. ALBERT GAUDRY has been elected vice-president of the Paris Academy of Sciences for the year 1902.

THE Symons Gold Medal of the Royal Meteorological Society will be presented to Dr. A. Buchan, F.R.S., at the annual meeting of the Society to be held on Wednesday, January 15.

WE regret to see that Prof. Virchow met with an accident on Saturday evening while alighting from an electric tramway car in Berlin. The injuries are described as a wrench to the hip joint and various contusions on the legs, in consequence of which Prof. Virchow will for a long time be confined to his room.

THE Commissioners of the Northern Lighthouses have decided to adopt wireless telegraphy as a means of establishing communication between the mainland and certain of their lighthouses. The first installation will be at the Flannan Islands, which are situated about sixteen miles outside the west coast of Lewis. The installation, which will be made in conjunction with Lloyd's shipping agency, will be on the Marconi system.

THE New York *Electrical Review* for December 21, 1901, contains some interesting particulars concerning Mr. Marconi's recent success in transmitting signals across the Atlantic by wireless telegraphy. It appears that before leaving England Mr. Marconi made arrangements for having the letter "S" signalled repeatedly at frequent intervals for three hours daily from his transmitting station at Poldhu. The power of the transmitting arrangements in Cornwall had been increased considerably since Mr. Marconi had succeeded in bridging a distance of 200 miles. At St. John's there was only a temporary station, the aërial wire being suspended from a kite at an altitude of about 400 feet. The transmitting and receiving arrangements were carefully tuned, the receiver being of a new type recently developed. On December 14 a succession of "S's" was received with unmistakable distinctness, and a similar series was received on the next day, but this time not quite so distinctly. Mr. Marconi attributes the variability partly to fluctuations in the height of the kite, bad weather prevailing at the time, and partly to the fact that the receiver had to be extremely sensitive and required constant adjustment. The erection of a permanent station in America and the increase in the power of the transmitters should remedy these two defects. It is now almost exactly 150 years since Franklin's classical experiment with a kite, which now, therefore, figures for a second time as important in the history of electrical development.

THE following news from Baron Toll's Arctic Expedition was received by the chief of the Central Meteorological Observatory at St. Petersburg, in a telegram, dated Yakutsk, December 4/17:—"On September 11/24 caught by winter in Nerpichiya Bay, 75° 22′ N. and 137° 16′ (E. longitude). From November 1 have opened meteorological station, with hourly observations. All right, all well. Sending greetings to Central Observatory. *Zarya*, October 25 (November 7), 1901." It will be remembered that the expedition started last summer on board the steamer *Zarya* with the intention of wintering somewhere on the Arctic coast of Siberia, so as to begin in the spring the exploration of the New Siberia Islands.

THE Russian newspapers publish the following official telegram, dated Yakutsk, December 28:—"The expedition which was sent out by the Academy of Sciences, under the zoologist Hertz, to examine the mammoth remains discovered in the district of Kolymsk, has reached Sredne Kolymsk, after a very difficult journey, bringing the mammoth with it. The animal was a male and apparently middle-aged. Its skeleton and skin have been preserved nearly intact. The tail was short and covered with long hair. In the stomach, between the teeth and on the tongue, remains of undigested food were found. The different parts of the mammoth have been conveyed to St. Petersburg in a frozen condition."

THE eleventh Congress of Russian Naturalists and Physicians was opened at St. Petersburg on January 2 by the Grand Duke Alexander of Oldenburg. The number of people anxious to take part in the Congress was very large, more than 3250 members' tickets having been taken on the day of opening. The Minister of Public Instruction has given a sum of 500*l.* to defray the expenses of the Congress, and both the Municipality of St. Petersburg and the University have contributed large sums for the same purpose. At the first general meeting of the Congress, the president (Prof. Menschutkin) spoke about the foundation of a Russian Association for the Advancement of Science, which would hold regular congresses every year. This proposal was accepted by a congress held eleven years ago; but the Ministry of Public Instruction was hostile to the idea, and only now the new Minister, General Vannovsky, has agreed not to oppose it. At the same general meeting Prof. S. M. Lukianoff delivered an address on the limits of cytological research under normal and pathological conditions, in which he endeavoured to establish the limits of psycho-physiology; and Prof. N. A. Umoff delivered a brilliant address on a physico-mechanical model of living matter.

THREE pleasure cruises have been arranged by our contemporary the *Revue générale des Sciences* to take place this year. At Easter there will be an excursion to Greece and the Greek Isles, in charge of M. C. Homolle, director of the French School at Athens, and M. G. Fougères, of the University of Paris. At the end of September there will be a trip to Syria and Palestine, directed by M. C. Diehl, and in November an excursion will be made to Egypt, up to the second cataract, under the direction of a well-qualified Egyptologist.

ON Tuesday next, January 14, Prof. A. Macfadyen will deliver at the Royal Institution the first of a course of six lectures on "The Cell, its means of Offence and Defence, Immunity." On Thursday, January 16, Dr. A. S. Murray will begin a course of three lectures on "Recent Excavations at Delphi and in the Greek Islands." The Friday evening discourse on January 17 will be delivered by Lord Rayleigh, his subject being "Interference of Sound." On January 24 Mr. H. G. Wells will give a discourse on "The Discovery of the Future," and on January 31 Prof. A. Crum Brown one on the "Ions of Electrolysis."

THE Decimal Association has sent us a list of 172 members of Parliament who have notified their approval of the compulsory adoption of the metric system of weights and measures into Great

Britain, and have promised to give their support to any measure brought forward with this end in view. The Association points out that, in the interests of our foreign trade, it is most desirable that we should at once carry this reform into effect, as the constantly reiterated statements of British consuls prove that much trade is lost because our weights and measures are not understood in countries where the metric system is in force. In Australia, Canada and Cape Colony the change would be welcomed; and seeing how easily so serious an impediment to commerce can be removed, it is hoped that the Government will give more attention to the subject in the coming session of Parliament than it has so far done.

IT is announced that a large sum of money—about 200,000*l*.—has been placed at the disposal of His Majesty the King for charitable or utilitarian purposes by Sir Ernest Cassel. This money, by the King's direction, is to be devoted to the erection of a sanatorium for tuberculous patients in England. For the carrying out of this purpose His Majesty has appointed an advisory committee consisting of Sir William Broadbent, Sir Richard Douglas Powell, Sir Francis Laking, Sir Felix Semon, Sir Hermann Weber and Dr. C. Theodore Williams, with Dr. Horton-Smith and Dr. John Broadbent as honorary secretaries. The institution is to accommodate 100 patients, and will be fully equipped with all requirements for scientific research. In fact, it is intended to construct the sanatorium on the best lines which past experience and original thought can suggest, and in order to obtain the most valuable opinions a sum of 800*l*. will be awarded in prizes for the best essays and plans upon the subject. Medical men of all nationalities may compete. The papers may either be the work of a medical man or the joint production of a medical man and an architect. All essays and plans must be sent, postage paid, on or before April 15, 1902, to one of the secretaries of the committee:—Dr. P. Horton-Smith, 15, Upper Brook Street, London, W.; or Dr. John Broadbent, 35, Seymour Street, London, W. Three money prizes, of 500*l*., 200*l*. and 100*l*. respectively, will be awarded in order of merit on the recommendation of the advisory committee for the three best essays, provided they come up to the requisite standard of excellence.

AN astronomical observatory has been erected and equipped by the Bengal Government at the Presidency College, Calcutta, and was opened a few days ago. The idea of providing means for the instruction of Indian youths in practical astronomy was conceived about five years ago, when the Maharaja of Tipperah presented to the Presidency College an equatorial telescope by Grubb, 4½-inch aperture. On Dr. J. C. Bose's representation, the Government of Bengal agreed to provide a building suitable for observations. But it was not until after the eclipse of January, 1898, when the professional and amateur astronomers who visited India caused active interest to be taken in building the observatory. From an article in the *Pioneer Mail* we learn that the chief instrument of the observatory is a 7-inch equatorial by Sir Howard Grubb, with an electrically controlled driving clock and with electric lights for all the graduated circles. The telescope will generally be used for eye observations, but the object-glass may be adapted to photography, and the mounting of the telescope is of a strength that will admit of its being used for spectroscopic examination of the sun or the brighter stars. The equipment will allow a considerable number of students to become familiar with the elements of astronomy in its most practical form. It is hoped that the Presidency College Observatory will yet be equipped with more instruments through private liberality.

THE Geological Survey of the Colony of the Cape of Good Hope has recently been working in Pondoland, and has secured a very fine collection of fossils from the Cretaceous rocks which occur along the coast near Natal. The most interesting find of all was one of a pair of lower jaws belonging to a large reptile allied to Mosasaurus. The large trenchant teeth are set, each in a cylindrical socket and arranged in such a way that there is a series of teeth firmly anchylosed to the socket and other successional teeth that are loose and have fallen into the hollow of the fixed teeth. Many detached bones were also found, but the whole deposit is littoral, and very little can be made out of these, as they have been much rolled about on a shingle beach before becoming imbedded. With the Mosasaurus bones there are numbers of flat plates belonging to the bony carapace of a turtle such as Protosphargis as well as such characteristic chelonian bones as the Y-shaped one composed of the scapula and procoracoid. A large number of sharks' teeth occur between the pebbles belonging to the genera Corax, Lamna, Otodus, Enchodus, Odontaspis, and a single Elasmobranch vertebra was found. Between sixty and seventy genera of Mollusca were obtained, including many finely preserved examples, some of which are new to science and a great many new to South Africa. Echinoderms and Polyzoa also occur, and eight species of Foraminifera, belonging to the genera Vaginulina, Nodosaria, Virgulina, Discorbina, Truncatulina, Textularia. The collection is now in the South African Museum, Cape Town, where the greater part is exhibited.

ALMOST nothing is known of the amount of rain on the mountains in Arctic regions. Mr. Hamberg has placed large permanent pluviometers on some high mountains in Swedish Lapland and has observed that much more snow and rain fall there than in adjacent low ground.

IN the *Popular Science Monthly* for December, 1901, Mr. H. Helm Clayton, of the Blue Hill Meteorological Observatory, discusses the influence of rainfall on commerce and politics. He gives a table of the annual departure from the normal rainfall in the Ohio and Mississippi valleys for a large number of years, showing, not only that every severe financial panic has been closely associated with persistent deficiency of rainfall, but that (with one exception) no period of protracted drought has occurred without a financial panic.

The Geographical Journal for November last contains a paper by Mr. H. N. Dickson on the mean temperature of the atmosphere and the causes of glacial periods. The conclusions of the author tend to show that considerably smaller changes of temperature and of the distribution and amount of precipitation, caused by the assumption of a lowering of mean temperature taking place by cooling in the polar regions, than has generally been supposed, enable us to account for the nature and distribution of glacial phenomena, as they are at present known to us.

THE only countries which took part in the international balloon ascents during September, October and November were Austria, France, Germany and Russia. Some of the greatest altitudes were attained from M. Teisserenc de Bort's observatory at Trappes, near Paris:—On September 5 (night ascent), 14,178 m., temperature $-55^\circ{\cdot}2$ C., on ground $5^\circ{\cdot}6$; on October 3 (night ascent), 14,500 m., temperature -58°, on ground $8^\circ{\cdot}1$; (day ascent) 13,150 m., temperature -53°, on ground 11°; November 7 (night ascent), 13,200 m., -62°, on ground $2^\circ{\cdot}4$. From Berlin, on this day, an altitude of 12,010 m. was attained, temperature $-58^\circ{\cdot}4$, ground $6^\circ{\cdot}5$. A manned balloon which left Berlin, height 1100 m., temperature $+1^\circ$, experienced a wind velocity of 80 kilometres (50 miles) an hour.

IN our notes columns we recently directed attention (p. 110) to a paper by Prof. Lebedew in which he described an experimental investigation of the pressure of light radiation. We have now received a paper on the same subject, by Messrs.

E. F. Nichols and G. F. Hull, which was read at a joint meeting of the American Physical Society and the American Association for the Advancement of Science on August 29, 1901, and is published in the *Physical Review* for November last. The experimental methods adopted by Messrs. Nichols and Hull are similar to those employed by Lebedew, the chief difference being that whereas the former used a bolometer to measure the incident energy the latter employed a calorimeter, but the investigation is not as yet of so complete a nature. The observations already completed are, according to the authors, sufficient to prove experimentally the existence of a pressure of the nature and order of magnitude of radiation pressure. The results agree to within about 30 per cent. with the theoretical value: a certain amount of inexactness is introduced as the authors did not experimentally determine the reflecting power of the vanes employed. Lebedew in his investigation claims to have obtained results agreeing to within 10 per cent. with the calculated values of the Maxwell-Bartoli pressure.

IN view of the trials now being made by one of the London water companies with ozonised air as an agent for water purification, the following details of the experimental plant erected by Siemens and Halske at Martinikenfelde, near Berlin, are of interest. This plant was erected in 1898, and is adapted for treating 240 cubic metres water per twenty-four hours. The ozonisers are of the Siemens and Halske plate and tube type, and yield 20-25 grams ozone per E.H.P. hour, with an E.M.F. of 12,000 volts. The air passing from the ozonisers under these conditions contains $2\frac{1}{2}$–3 grams ozone per cubic metre. An air-pump is used to force the air through the drying chamber into the ozonisers, and it passes thence into the sterilising tower. This tower is a simple square structure packed with flints, and as the ozonised air passes upwards it comes into contact with a descending stream of water. The remainder of the plant at Martinikenfelde consists of a water-pump, a sand filter for preliminary filtration of the water with which the sterilising tower is fed, and various storage tanks for the filtered and unfiltered water. Tests made with water from the River Spree show that the numbers of bacteriological organisms were reduced from 600,000 to 10 per cubic centimetre. The permanganate absorption figure was reduced 18 per cent., and the aëration of the water was increased from 10 per cent. to 12 per cent. The consumption of ozone amounted to two grams per cubic metre. The cost of treatment for an installation treating 120-150 cubic metres per hour was estimated to be 1·726 pfg. per cubic metre, and the total cost, when interest and depreciation charges on the distributing system are included, 5·031 pfg. per cubic metre (equal to 1*s.* 5*d.* per 1000 cubic feet). The capital outlay upon an installation capable of treating 150 cubic metres per hour was estimated to be 6750*l.*, of which total 3750*l.* represented the expenditure upon the ozonisers and sterilising tower. Further details will be found in an article by Dr. Erlwein in the *Zeitschrift für Electrochemie*, November 14, 1901.

MR. SEALE, in *Occasional Papers* (vol. i. No. 4) of the Bernice Pauahi Bishop Museum, Honolulu, describes and figures several new Hawaiian marine fishes.

IN the *Comptes rendus* of the Swiss Society of Natural Science for 1900 Dr. Fatio adds two vertebrates—the lesser shrew (*Sorex pygmaeus*) and the Grecian frog (*Rana graeca*)—to the fauna of Switzerland.

IN an article published in the *Revue Scientifique* (*Revue Rose*) of December 28, 1901, M. Hugo de Vriês discusses the mutations of species and the periods required for such mutations. He mentions that since certain plants have apparently remained unaltered since the date of the building of the pyramids (approximately 4000 years), this period may be taken as a minimum unit in estimating the time required for specific modification.

To the eighty-third volume of the *Verhandlungen* of the Swiss Naturalists' Society Prof. C. Keller communicates a very interesting dissertation on a peculiar breed of domesticated sheep with goat-like horns formerly kept by the natives of the Bünden Oberland, Switzerland, and hence locally known as the Bündnersch. The breed is known to be of great antiquity, but now appears to be almost exterminated owing to crossing with other strains. In 1862 the late Prof. L. Rütimeyer called attention to the peculiarity of this breed, and indicated its near affinity with the so-called peat-sheep (*Torfschaf*) of the Swiss lake-dwellings, of which it appears to be the direct descendant. The author expresses the hope that efforts may be made to save the breed from extinction.

WE are glad to have the pleasure of congratulating the editor of the *Zoological Record* on the completion of the volume for 1900. Year by year his task grows more onerous, the volume before us exceeding its predecessor by 180 pages. Very noticeable is the length of the list of new generic and subgeneric names, which contains no less than 2102 entries, the maximum having been previously 1707, in 1895. The increase in the bulk of the volume is largely due to the insect record, which comprises 354 pages against 276 in 1899. The yearly growth in the size of the volume is, of course, largely to be attributed to the practice of naming local races of animals, which has come so largely into vogue of late. The various recorders appear to have done their work with great care and thoroughness, although we notice in the mammal part that one paper (No. 200) is credited to a writer other than its author. Uniformity in regard to the "introduction" to the different "records" is still a desideratum, this important element being altogether omitted in some instances, while in one case it has been allowed to reach an altogether disproportionate length. It is a decided improvement in the "get-up" that in this year's issue the edges have been cut. We are glad to hear that there is a good prospect of the promised "index volume" of generic names making its appearance early in the year.

NONE have laboured more earnestly on the land and freshwater Mollusca of Pleistocene and recent times in Britain than Messrs. A. S. Kennard and B. B. Woodward. Their latest work, "The Post-Pliocene Non-Marine Mollusca of the South of England," has just been published by the Geologists' Association (*Proc.* vol. xvii. November 1901). In this the lists from various localities have been carefully checked and revised whenever possible from an examination of the actual specimens recorded. Doubtful records are omitted from the general list, in which are tabulated the species from seven Pleistocene and thirteen Holocene localities. There is also a column showing the species which occur in Pliocene deposits, and another giving all the living British species. Of the 139 living species no less than 129 occur in the south of England, and of the ten extinct forms seven have been found in the same area. The authors have expressed their opinion that the Pleistocene molluscan fauna was a finer one than that of to-day. The non-marine Mollusca have reached this country from various sources. In their opinion a large number are boreal, and of these some travelled hither along the now sunken land to the north of Scotland, whilst others may have journeyed through Siberia and the Continent; some have come from the south by the old land connection between England and the Continent; while others, the so-called Lusitanian forms, have reached us from south-west Europe; a few species may be endemic. Some changes in nomenclature are noted, but the authors justly remark that the identity of the shell is of more

importance than the absolute correctness of the name from a "priority" point of view.

IN *Publication* No. 56 of the Field Columbian Museum Dr. G. A. Dorsey describes the results of a fortnight's digging in the island of La Plata, Ecuador. It seems probable that for a very long period the island was visited by people from the mainland for ceremonial purposes, as none of the pottery appears to have had any utilitarian use, practically all being of the nature of images of the human form ranging in height from six to twenty inches, and most of them were provided with whistles. There were found numerous engraved and plain rectangular and circular discs and other problematical objects. In a tongue of detrital soil near the shore was found a grave which, from its contents, belonged to another occupation of the island, and there can be little doubt that invaders from Peru previous to the Spanish conquest were buried in this little island so remote from their home. In the grave excavated by Dr. Dorsey were found two gold human figures, one of silver, one of bronze and one of copper, besides a gold cup and several objects in gold, silver and copper, twelve earthenware vessels and a magnificent ceremonial highly polished stone axe, 19½ inches long and less than three-quarters of an inch thick, which may be considered as one of the most remarkable stone implements ever found. The paper is illustrated with sixty-three excellent plates and several figures. The letterpress is exceptionally condensed; a little more amplification would have been an improvement, and the sizes of the objects should have been given. An English observer fails to see why what appears to be a very evident alligator which surmounts a fragment of a human head in pottery should be termed a "serpent head-dress." The prominent valvular nostrils, the character of the eye, the keeled dorsal scutes and the limbs are essentially crocodilian, as is also the prominent lateral tooth in the upper and *lower* jaw; the latter cannot be the "projectile fangs of a serpent."

AT a recent meeting of the Linnean Society, Prof. S. H. Vines gave the results of his recent investigations of the proteolytic enzymes of plants, especially that of the pitchers of Nepenthes. The application of a chemical test—the pink or violet colour produced by the addition of chlorine water—shows that the enzyme in Nepenthes is tryptic, and not peptic; and this is probably the case with all ferments found in the vegetable kingdom. Prof. Vines proposes the term nepenthin for the ferment of Nepenthes.

THE *Journal* of the Royal Microscopical Society for December, 1901, contains the usual annual list of new biological terms (zoology and botany) introduced during the year. In the *Transactions* of the Society is a paper by Miss A. Lorrain Smith, on work carried on in the laboratory of the Royal Agricultural Society, on fungi found on farm seeds when tested for germination. A new genus of fungi, Stemphyliopsis, is described.

THE bulky part of the *Journal* of the Royal Horticultural Society for December contains a full report of the Lily conference held in the Gardens at Chiswick on July 16, 1901. The wide spread of the lily-cult is shown by the fact that at that meeting no fewer than eighteen papers were read, on the culture of lilies, their species and varieties, their diseases, &c. The most important original paper in this number is one by Sir James Blyth, on vine culture as exemplified at the Paris Exhibition.

THE Imperial Department of Agriculture for the West Indies has just published pamphlet series Nos. 12 and 13. The former, "Seedling and other Canes in the Leeward Islands, 1900–1901," is a summary of the report on sugar-cane experiments conducted at Antigua and St. Kitts recently noted here. The other, "Seedling and other Canes at Barbados, 1901," is a summary of an address delivered to the Barbados Agricultural Society by Prof. D'Albuquerque and Mr. Bovell, giving the results of the experimental cultivation of selected canes during last year. In the earlier stages of the experiments the weather seems to have been all that could be desired, and things looked so promising that a bumper crop was predicted; but at the critical moment, when good rains were essential for the complete fulfilment of the prediction, an all but universal drought settled down on the island and lasted until the canes were reaped. When the harvest time arrived the wind dropped so light that the windmills could not be worked. The canes were therefore growing long after they ripened, and when cut they were often standing some days at the mill door waiting for the wind to crush them. This combination of adverse weather had much to do with the poor quality of sugar that in many instances was turned out for sale. Seedling B. 208 proved the best all-round cane, the indicated muscovado sugar yield being 2·6 tons per acre (being second in 1900 with 3·02 tons). White Transparent was second with 2·5 tons (in 1900 it was eighth with 2·41 tons), and B. 147 third with 2·4 tons (in 1900 first, with 3·1 tons). B. 156, B. 306, B. 347 and Rock Hall cane produced impure juice and D. 130 and D. 145 yielded such a small tonnage of canes that their further experimental cultivation is undesirable.

MESSRS. PENROSE AND CO. have sent us a copy of their new, strongly bound and most luxurious catalogue of their apparatus and supplies, which contains particulars of almost every appliance or material known to be used in photo-mechanical processes, and is the most complete catalogue of process appliances with which we are acquainted. The book, which consists of 272 pages of matter printed on excellent paper, contains also 750 illustrations, many of which are by the half-tone process, and there are also 1260 references in the index. It may be added that the catalogue is supplied free of charge to regular customers and will be sent to prospective customers on receipt of half a crown, which will be refunded on the first order for goods to the value of one pound or upwards.

A VALUABLE collection of books and tracts on pure mathematics exists in the Central Library, Newcastle-upon-Tyne, and the catalogue prepared by Mr. Basil Anderton, chief librarian, and just issued by the Newcastle Public Libraries Committee, should be the means of making the collection more widely known than it is. Only works on purely mathematical problems are included, but the extent of the collection may be judged by the fact that the titles of such books and tracts in the reference library occupy forty-five closely printed quarto pages. The works are arranged alphabetically according to authors, and, so far as possible, related writings by the same author have been brought together. The committee of the Library is anxious that the books should be abundantly used, and the catalogue has been issued with this end in view.

THE Annual Report of the Smithsonian Institution for 1900 was received a few days ago, and, like the reports of previous years, it is a volume which commands admiration. The account, given by Dr. S. P. Langley, of the position and progress of the Institution occupies 117 pages and is naturally of restricted interest; but following it are no less than forty-three papers, occupying 643 pages, with numerous plates, selected from the scientific publications of the year because of their importance in illustrating directions of scientific thought, and containing trustworthy accounts of progress in physical and biological discovery. It is scarcely too much to say that every subject in which the world of science is interested finds its way in the course of time into Dr. Langley's comprehensive repertory. The articles which are reprinted or translated are chiefly by men of science of first

rank engaged in the extension of natural knowledge. The present volume contains reports upon scientific work, as, for example, those by Dr. Langley upon observations of the solar eclipse of May 28, 1900, the new spectrum, and the Langley aërodrome; scientific articles from magazines, as Sir Norman Lockyer's account of the progress of astronomy during the nineteenth century, Prince Kropotkin's article on unsuspected radiations, and the late Dr. J. Fiske's reminiscences of Huxley; presidential addresses, as Prof. W. J. Sollas's address on evolutional geology, delivered before the British Association in 1900, and Dr. G. M. Sternberg's address on malaria; several papers read before scientific societies, as one by Prof. V. B. Lewes on incandescent mantles, and Mr. E. S. Grogan's paper, read before the Royal Geographical Society, on his journey through Africa from the Cape to Cairo; original articles on Chinese folklore, and the restoration of extinct animals, and several translations, among which we notice a paper by Dr. Janssen on the progress of aëronautics, and one by Dr. F. Delitzsch on discoveries in Mesopotamia. In addition to these articles there are a number of others dealing with the progress of various branches of science during the nineteenth century. We are grateful to Dr. Langley for collecting these contributions to scientific literature from many sources and rendering them easy of access in his annual anthology.

THE additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (*Macacus sinicus*) from India, presented by Mr. L. E. Carmalt; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. W. H. Sheridan; a Black-eared Marmoset (*Hapale penicillata*) from South-east Brazil, presented by Mrs. Augusta Ryland; a Common Squirrel (*Sciurus vulgaris*), British, presented by Mr. R. B. Hatfield; a Red-faced Spider Monkey (*Ateles paniscus*) from Guiana, a Barnard's Parrakeet (*Platycercus barnardi*) from South Australia, five Conical Eryx (*Eryx conicus*), a Long-snouted Snake (*Dryophis mycterizans*), a Hamilton's Terrapin (*Damonia hamiltoni*) from India, two Black-headed Terrapins (*Damonia reevesi unicolor*) from China, deposited; two Coscoroba Swans (*Coscoroba candida*) from Antarctic America, purchased.

OUR ASTRONOMICAL COLUMN.

THE ANNULAR ECLIPSE OF THE SUN, NOVEMBER 11, 1901.—The successful observation of this eclipse by M. A. de la Baume Pluvinel at Cairo was announced by telegram some time ago, and his complete report of the operations appears in the *Comptes rendus* (vol. cxxxiii. pp. 1180–1185). Although the results were in general successful, the conditions were somewhat unfavourable owing to the low altitude, about 15°, of the sun at mid-eclipse.

Three lines of investigation were attempted.

(1) The examination of the solar spectrum at grazing incidence on the moon's surface. This was done with a powerful grating spectrograph, using an image of the sun about 14 mm. diameter on the slit plate. No variation in the various groups of lines examined could be detected, and it was concluded that this rendered the existence of any lunar atmosphere extremely improbable.

(2) Photographs of the crescents presented at second and third contacts were obtained in the hope of detecting any difference in constitution between the chromosphere and the outer photospheric layers. These were taken with a small prism spectrograph, having condenser, collimator, and camera objectives all about 0·60 metre focal length. A considerable number of arcs were obtained, and a list is given showing their wave-lengths in comparison with Young's chromospheric lines. The main series of arcs corresponded to a chromospheric layer about 20″ of arc in height, but beside these there appeared a series of more feeble images corresponding to a layer some 40″ high. The absence of the hydrogen series so conspicuous in the chromospheric spectrum is attributed to the mutual action of chromospheric radiation and photospheric absorption.

(3) Attempts to photograph the corona in presence of sunlight. This had appeared feasible in consequence of the impressions obtained several seconds after totality during the eclipse of January 1898, in India. For this work he employed a Cooke triple photo-visual objective of 1·5 ometres focal length. This instrument and the image lenses of the two spectrographs were fed by 3 plane mirrors mounted on a single cœlostat.

As the diameters of sun and moon differed by 1′ 24″ there were about 16/100ths of the sun's disc still visible at mid-eclipse. Two photographs, with 3 seconds and 10 seconds exposure, were obtained, but the aureole shown is not thought to be truly coronal.

Attempts were also made to detect the corona by utilising the action of the calorific rays on phosphorescent substances, but with negative results.

THE MAMMALS OF NORTH AMERICA.

AMONGST the recently issued publications of the Field-Columbian Museum of Chicago we find a list of the land and sea mammals of North America, north of Mexico, prepared by Mr. D. G. Elliot, curator of the department of mammals in that institution. The list is stated to contain the names of all the forms of North American mammals found on land or in the adjacent seas which had been described up to the date of publication (June 10, 1901), at any rate all those that "under the most lenient treatment are entitled to any sort of consideration." This most useful catalogue serves to show us very plainly the great activity of the American zoologists in this particular department of their science during recent years. In the late Prof. Baird's work on North American mammals, published in 1857, only 220 terrestrial species of this class (not including the bats) were recognised as occurring in the northern portion of the American continent, besides thirty-six others which were considered as of doubtful authenticity. Mr. Elliot's list contains the names of 628 species besides 368 subspecies, so that, if we take it as correct, the number of recognisable forms of North American mammals has been enormously increased of late years. It will be interesting to ascertain in what groups of the class of mammals this great augmentation has mainly taken place. This is shown in the following tabular statement:—

	Elliot, 1901			Baird, 1857
	Sp.	Subsp.	Total	Sp.
Order i. Marsupialia	2	1	3	2
,, ii. Edentata	1	—	1	1
,, iii. Sirenia	2	—	2	—
,, iv. Cetacea	46	2	48	—
,, v. Ungulata	25	11	36	15
,, vi. Rodentia	380	255	635	130
,, vii. Carnivora	88	62	150	46
,, viii. Pinnipedia	14	—	14	—
,, ix. Insectivora	47	22	69	26
,, x. Chiroptera	23	15	38	—
	628	368	996	220

In considering these figures it must be remarked that as Baird did not include the three groups of marine mammals or the Chiroptera in the scope of his work no complete comparison can be made. But it will be obvious, on a glance at the comparative tables, that it is the smaller mammals, the Rodents and Insectivores, that have so greatly increased in multitude, according to the present fashion of dealing with them. The Rodents, of which Baird only recognised 130 in North America, are now supposed to number 380 species, besides 255 subspecies,

and the Insectivores have risen from 26 species to 47 species and 22 subspecies. It is, of course, only natural that a considerable increase of species should have taken place in both these groups, as numerous and active collectors sent out by the United States National Museum and by the Agricultural Department at Washington have of late years traversed every part of the large western States and the adjoining districts of Mexico, where the members of these two groups are found in abundance. The collections thus made have been worked out by Dr. C. Hart Merriam, Mr. Allen and other well-known American naturalists, who have specially devoted their energies to the study of these groups of mammals. It may be fairly stated that in the opinion of many naturalists (who perhaps in these days would be pronounced to be somewhat old-fashioned) the process of the subdivision of species (vulgularly called "splitting") has, in some cases, been carried too far, especially as regards subspecies. At the same time there is no doubt about the high character of the work executed so diligently by Dr. Merriam and his *confrères*. We may point out, however, that the same kind of subdivision has been carried on also, to a certain extent, amongst the larger mammals. On turning over the pages of Mr. Elliot's "List" it will be noticed that the reindeer (*Rangifer*) of North America, which the old-fashioned naturalists have hitherto classed as being specifically inseparable from the European form (*R. tarandus*), is now held to consist of seven different species, and that the Rocky Mountain sheep, of which, until lately, only a single species was generally recognised, has been split into four or five species. Referring to the Carnivora, we find the southern lynx (*Felis rufa*) divided into nine subspecies, and the Virginian fox (*Canis virginianus*) into seven subspecies. The bears of North America, according to Mr. Elliot's "List," now consist of nine species, besides three subspecies. We in Europe have been accustomed to refer them all to three species only. In a similar way the skunks of North America (*Mephitis*) of which Baird only recognised five species, are now held to number no less than twenty species and four subspecies, divided into three genera.

What we have stated (to which more remarks of a similar character might easily be added) will serve to show that a great revolution is now taking place in the mode of treating the mammals by American workers. Symptoms of the same class of work have also occurred in Europe, but the process has not been carried on here to so great an extent, nor has it met with such general acceptance. Whatever may be its results it will certainly be necessary to add greatly to the space now occupied by the mammals in museums of natural history, for it is only a very large series of specimens that will enable the conscientious student to decide between the opposing claims of the "splitters" and the "lumpers," and to decide what are species and what are subspecies.

PRIZE SUBJECTS OF THE PARIS ACADEMY OF SCIENCES.

THE *Comptes rendus* of the Paris Academy of Sciences for December 16, 1901, contains a list of the prizes proposed for the years 1902, 1903. 1904, 1905 and 1906. The subjects proposed for the current year include the following :—

Geometry.—The subject proposed for the grand prize of the mathematical sciences is to perfect, in an important point, the application of the theory of continued groups to the study of partial differential equations; for the Bordin prize (3000 fr.), to develop and perfect the theory of surfaces applicable to the paraboloid of revolution; the Francœur prize (1000 fr.) and the Poncelet prize (2000 fr.) will be awarded for works useful to the progress of pure or applied mathematics.

Mechanics.—The Plumey prize (2500 fr.) for an improvement in the steam engine or any other invention contributing to the progress of steam navigation; a Montyon prize (700 fr.) for invention or improvement of instruments; extraordinary prize of 6000 fr. for any invention tending to improve the efficacy of the French naval forces.

Astronomy.—The subject announced for the Damoiseau prize (1500 fr.) is the completion of the theory of Saturn as given by Le Verrier, publishing the rectifying formulæ and establishing the agreement between theory and observation; the Janssen gold medal for an important discovery in physical astronomy; and the Lalande (540 fr.) and Valz (460 fr.) for general work in astronomy.

Geography and Navigation.—The Binoux prize (3000 fr.) will be awarded for the best work on this subject.

Physics.—The Hébert prize (1000 fr.) for a practical application of electricity.

Statistics.—A Montyon prize (500 fr.) for a memoir on the statistics of France.

Chemistry.—The Jecker prize (10,000 fr.) for work tending to the progress of organic chemistry.

Mineralogy and Geology.—The Fontannes prize (2000 fr.), to the author of the best palæontological publication.

Physical Geography.—The Gay prize (2500 fr.) for a memoir on the progress realised in the nineteenth century in the study and representation of the earth.

Botany.—The Desmazières prize (1600 fr.) will be awarded, independently of nationality, to the author of the best work on cryptogams; the Montagne prize (500 fr.) for a memoir on the anatomy, physiology or development of the lower cryptogams.

Anatomy and Zoology.—The Savigny prize (1500 fr.) for the assistance of young travelling zoologists, not receiving Government assistance, who occupy themselves especially with the invertebrates of Egypt and Syria; the Vaillant prize (4000 fr.) for the study of the fauna of an Antarctic island of the Indian Ocean; the Thore prize (200 fr.) for the best work on the habits and anatomy of a species of European insect.

Medicine and Surgery.—A Montyon prize for works useful in the art of healing; the Barbier prize (2000 fr.) for a valuable discovery in surgical, medical or pharmaceutical science; the Breant prize (100,000 fr.) for the discovery of a radical cure for Asiatic cholera, or for indicating in an indisputable manner the causes of Asiatic cholera in such a manner as to lead to its suppression, or, failing this, the interest on the capital sum will be awarded for a rigorous proof of the existence in the atmosphere of matter capable of taking part in the production or propagation of epidemic diseases, or for the discovery of a radical cure for herpes or for clearing up its etiology; the Godard prize (1000 fr.) for the best memoir on the anatomy, physiology or pathology of the genito-urinary organs; the Serres prize (7500 fr.) for the best work on general embryology, applied, as far as possible, to physiology and medicine; the Bellion prize (1400 fr.); the Mège prize for an essay on the causes which have retarded or favoured the progress of medicine from the oldest times to the present day; the Lallemand prize (1800 fr.) for work on the nervous system; and the Baron Larrey prize (1000 fr.) for the best work presented to the Academy treating of military medicine, surgery or hygiene.

Physiology.—A Montyon prize (750 fr.); the Pourat prize (1400 fr.) for a memoir on the comparative study of the mechanism of respiration in mammals; the Martin-Damourette prize (1400 fr.) and the Philipeaux prize (880 fr.) for work in experimental physiology.

General prizes.—The Arago medal is awarded by the Academy in recognition of a work or discovery of the first rank; the Lavoisier medal is awarded without distinction of nationality to chemists who have rendered eminent service to their science; a Montyon prize (unhealthy trades) for discoveries or inventions diminishing the dangers of any unhealthy trade; the Wilde prize (4000 fr.), awarded without distinction of nationality, for that work or discovery which, in the opinion of the Academy, is best worthy of recompense in astronomy, physics, chemistry, mineralogy, geology or experimental mechanics; the Tchihatchef prize (3000 fr.) for exploration in the lesser-known parts of Asia; the Delalande-Guérineau prize (1000 fr.) for services rendered to French science; the Jérome Ponti prize (3500 fr.); the Houllevigue prize; the Cahours prize (3000 fr.) for the encouragement of young men already known for their work, especially in chemistry; the Saintour prize (3000 fr.); the Trémont prize (1100 fr.); the Gegner prize (3800 fr.); the prizes founded by Mme. la Marquise de Laplace and by M. Félix Rivot.

Of these prizes some are explicitly and others tacitly restricted to Frenchmen; among those expressly stated to be offered without restriction of nationality are those bearing the names of Leconte, Tchihatchef, Wilde, Lavoisièr, Arago, Desmazières, Delesse, La Caze, Lalande and Pierre Guzman.

PHOTOGRAPHS OF SNOW CRYSTALS.

MR. W. A. BENTLEY, of Jericho, Vermont, U.S.A., has devoted twenty years to the study of snow crystals, with special reference to the relation between their forms and the atmospheric condition at the time of their fall. He gives in the U.S. *Monthly Weather Review* a short account of the results of his investigations; and a number of beautiful reproductions of photomicrographs of snow crystals secured by him accompany his paper. By the courtesy of Mr. Willis L. Moore, chief of U.S. Weather Bureau, we are able to give several of these pictures and an abstract of Mr. Bentley's contribution referring to them. So far as we are aware, no more beautiful or complete collection of photographs of snow crystals has ever been obtained than that produced by Mr. Bentley's patient work, and the fact that he has prosecuted his studies in somewhat difficult circumstances for so long is an excellent testimony to his scientific enthusiasm. We understand that he is preparing a volume upon the photographs, and the results of his studies of them. An album containing prints of all his drawings and photographs, with a short description of the methods and conclusions, would certainly be of great scientific value. The following notes are abridged from his paper in the *Monthly Weather Review*.

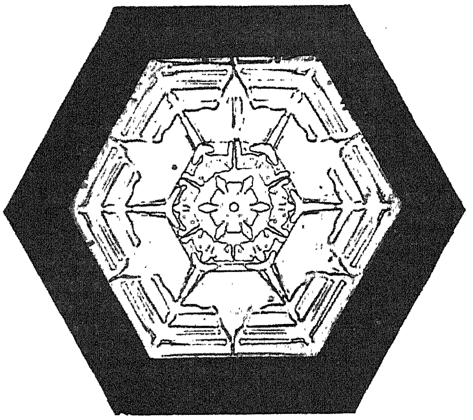

FIG. 1.—1895, February 8. Wind north-west, temperature −4° F.

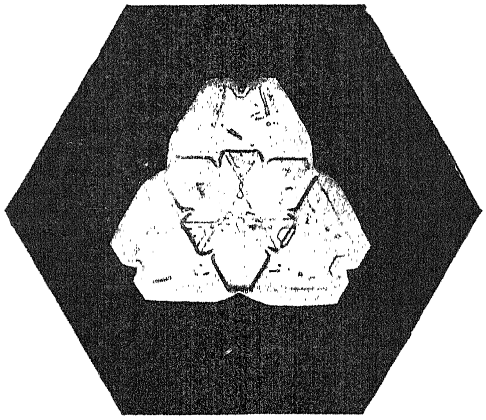

FIG. 2.—1900, February 18. Wind west to north-west, temperature 11°.

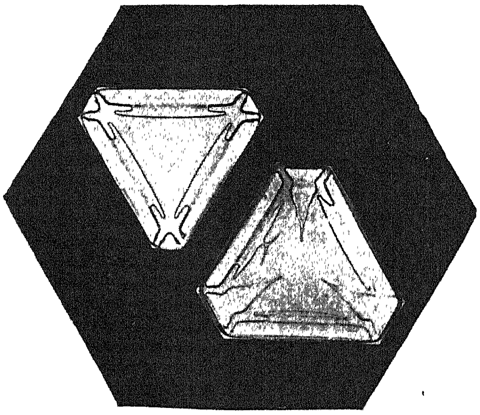

FIG. 3.—1899, February 13. Wind north, temperature 1°.

Photographs have been secured during every winter since 1884, and they now number more than 800, no two alike. Nearly every great and famous winter storm since that date has furnished its quota of from four to twenty (and in one instance thirty-four) of new forms to this collection. At the same time, observations have been made and data secured, while photographing them, of the temperature; kinds and approximate heights of clouds (when possible); the direction and rapidity of movement of various cloud strata; the direction and velocity of the surface winds; also changes in the forms of the crystals form hour to hour as the different portions of each storm passed over the district. The latter observations were made to ascertain whether there was any general law of distribution of the forms within the different portions of a storm. Differences in form of crystals deposited by local storms from those of general storms were also noted, as also

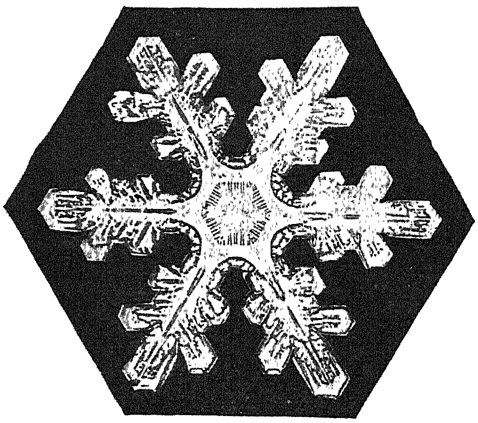

FIG. 4.—1900, December 5. Wind north-west to north, temperature 22°. Cloud, stratus.

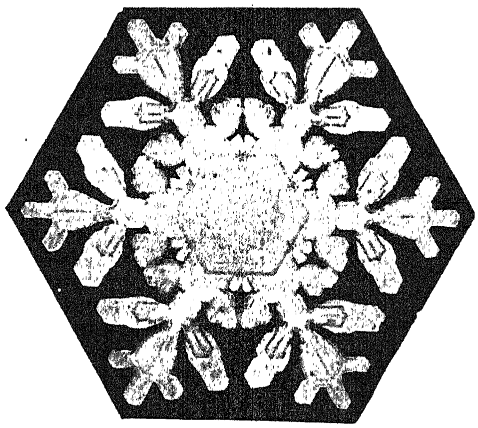

FIG. 5.—1888, March 12. Great blizzard, temperature 12°. Diameter one-quarter of an inch.

the forms originating in, and peculiar to, each of the various cloud strata. These observations, and the data secured, indicate that the temperature and the humidity of the air at the earth's surface is a much less important factor than is generally supposed in determining the form and size of humidity due to these; the character of the storm, whether local or general, and the portion of the storm region from which the crystals come. To these must also be added the initial and subsequent movement of the crystals within the clouds. If, as must often be the case, the nuclear forms originating in the

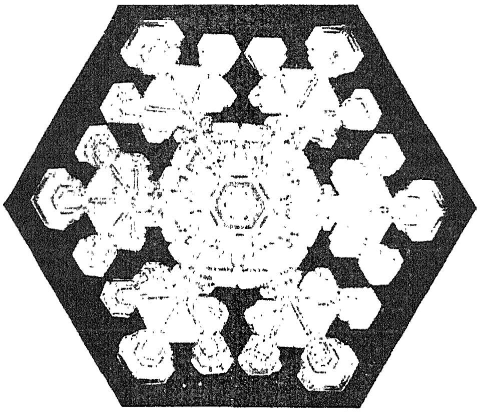

FIG. 6.—1901, February 15. Wind north-west, temperature 14°.

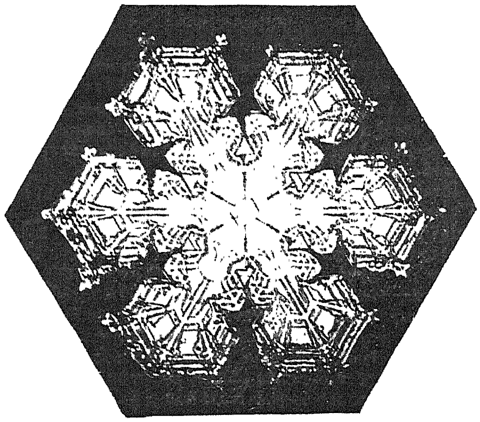

FIG. 7.—1898, January 26. Wind changing west to north-west, temperature 18°.

the crystals. We may easily conceive this to be the case, because at a given temperature, &c., at the earth's surface, the temperature and humidity of the air where the crystals form might vary greatly, one time from another, and would depend largely upon the height of the snow-producing clouds. The height of these varies greatly at different times, even when the temperature at the earth's surface remains the same. The data secured have not revealed the great mystery of the origin and cause of the differences in the forms of the nuclei; why columnar forms predominate at one time, tabular forms at another, or why both are sometimes found associated together. Much has been learned, however, of the conditions tending

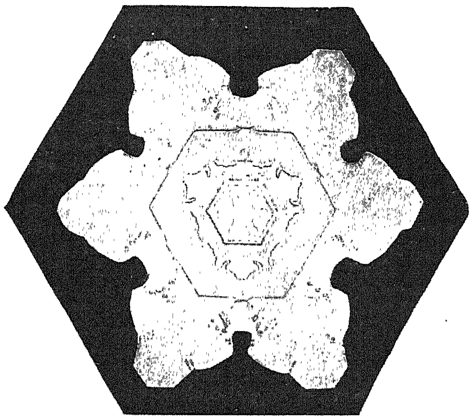

FIG. 8.—1899, January 6. Wind south-south-east, temperature 22°. Clouds, upper stratus.

lower ascending clouds are carried upward to much greater heights by the strong ascending air currents, which often occur within such storms, until they become heavy enough to fall back through them, then the crystals will in all probability be greatly modified by passing through atmospheric strata varying greatly in density, temperature, humidity, &c. That they are greatly modified by these flights in the clouds is clearly shown by the interior structure of many of the crystals outlining many of these transitory states. Thus, crystals of which the nuclear form was originally nearly perfectly hexagonal sometimes become partly triangular in outline, and *vice versâ*. No. 8 is an example of such modifications.

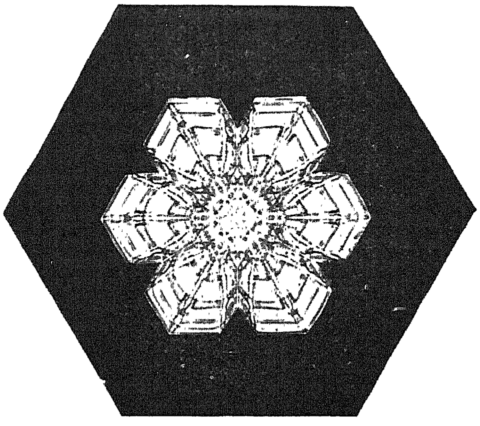

FIG. 9.—1886, February 26. Wind north-west, temperature 8°.

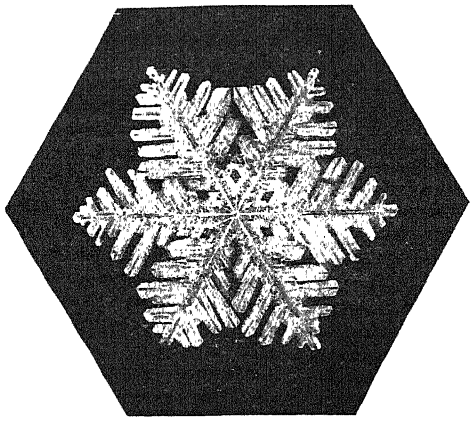

FIG. 10.—Wind west, temperature 34°.

to modify their forms after the nuclear form is once organised. These conditions are many, the chief among them being the height, number and vertical depth of the cloud strata and the resultant variation in temperature, atmospheric pressure and

Perhaps the most important facts of a general nature to be gleaned from twenty years' study are these:

(1) That the greater number of the more perfect and beautiful tabular forms occur much more frequently in, and are confined

almost wholly to, the western and north-western portions of great storms and blizzards.

(2) That there seems to be a law of general distribution of the different forms, the columnar to one, the tabular and granular to others, with many varieties associated together in other portions of such great storms.

(3) That this distribution is, with few exceptions, constant, that is, the same in nearly all storms.

Sufficient data has not as yet been collected to demonstrate beyond all doubt the fact that this law applies to all forms of crystals and to all storms alike.

Passing on to the variation in form of those crystals deposited by local storms, as compared with those of general storms, we find that these are very marked, except during intense cold.

The local storm types and those precipitated from low, detached clouds usually consist of large, frail, branching, tabular forms, devoid of a solid tabular nucleus (see No. 10), or of heavy granular varieties, similar one to the other, each according to its class. On the other hand, those deposited by general storms are usually more diversified in form and more complex in structure, the snowfall often consisting of two or more varieties associated together. The larger and more perfect columnar prisms, columnar forms possessing tabular outgrowths at one or both ends (which we might call doublets), truncated triangular forms (see Nos. 2 and 3), and solid tabular forms, the latter often possessing wonderfully beautiful and complex interior designs (as in No. 1), are common only to general storms. Branching tabular and granular forms are common to both general and local storms, but they ordinarily possess solid nuclei if deposited from a general storm (as in Nos. 4–7), whereas the nuclei are generally absent (as in No. 10) if the crystals originated in local storms. During zero weather the crystals of local storms approach much nearer in form to those of general storms, and we find solid tabular forms, branching tabular forms possessing solid hexagonal nuclei and sometimes doublets, among the snowfall. Often during the intense cold succeeding a blizzard the snowfall will consist wholly of very minute columnar and pyramidal forms, or of both columnar and minute frost-like tabular forms, falling apparently from low, detached nimbus or alto-nimbus clouds, or even from a sky free, or nearly so, of clouds.

During relatively mild temperatures each cloud stratum, if alone, there being no other clouds either above or below them, commonly precipitates each its own peculiar type of crystals. Low detached nimbus clouds deposit large, frail, branching tabular forms, similar to No. 10; intermediate clouds, smaller, branching tabular forms, possessing solid hexagonal nuclei; and the high cirro-stratus clouds, small compact columnar and tabular forms. The large cumulus clouds of spring and autumn usually shed large, heavy, pyramidal-shaped granular snow. These granular forms frequently, if not invariably, possess nuclei of branching, tabular forms, and are usually precipitated when the temperature is near or somewhat above the freezing point.

Of the photomicrographs which accompany this article all, with the exception of No. 10, are those common to and were deposited by great storms.

Of the other numbers of the series, No. 2 is very rare and unusual, containing as it does eleven triangular divisions within its outlines. Apparently the lines of greatest growth were reversed during one stage of the growth of this strange form, thus differing widely from No. 3, which has outlines somewhat similar. No. 4 possesses a very rare unique nuclear design which is very difficult to explain by any process of crystallisation of which we know. No. 5 (a souvenir of the great blizzard of March 12, 1888) is very symmetrical, as also is No. 6, of February 15, 1901. No. 7 is, in all but the unimportant outermost points, a marvel of complexity and perfect symmetry. No. 9 is also a marvellously beautiful and symmetrical example of snow architecture.

Passing to the causes governing the formation of the nucleus, whether it be columnar or tabular, the electrified state of the atmosphere, whether negative or positive, and perhaps, also, as suggested by Prof. Cleveland Abbe, the presence in greater or less amounts of various gases and vapours in the atmosphere, may all be controlling factors.

Although much has been already learned about these interesting phenomena, yet there still remains much more. Cooperation between many observers is essential to carry out this work successfully. Simultaneous observations of the forms and changes the crystals undergo from hour to hour during our great blizzards should be made by many skilled observers, stationed along a general line extending north and south. These observers must be familiar with the names and approximate heights of the various clouds. This study should include observations of the kind and approximate height and direction of drift of the various clouds, direction and force of the surface wind, temperature of the air, and amount of moisture at the earth's surface; also its electric condition, whether negative or positive, and the portion of the storm from which the crystals emanate.

It is also highly desirable that observations be made to ascertain why the perfect crystals are more common in the western portion of storms, and also why certain portions produce certain types.

Such a study, supplemented by investigations as to the causes of the formation of the two fundamental types of hoar-frost crystals, would doubtless lead to the discovery of very many of the mysteries surrounding the origin and history of the wondrously beautiful forms of snow.

A NEW JOURNAL OF ANATOMY.

THE first number of a new scientific magazine—*The American Journal of Anatomy* (Baltimore, November 1901)—has been received and merits a descriptive notice because, as it has been "founded to collect into one place, and present in a worthy manner, the many researches" of American anatomists, it marks a new departure in scientific journalism, and while its pages are but 98 in number we are informed that future issues will be in quarterly parts of about 125 pages each. The interest with which British anatomists regard their branch of science as practised in America has during the last four to five years been heightened by the association, as joint editor of our own long-established *Journal of Anatomy and Physiology*, of Prof. G. S. Huntington, of the Columbia University at Washington, who is one of the chief promoters of the new journal now under review. The reason of this enhanced interest lies in the fact that his connection with the English publication was marked by the appearance in its pages of a paper of a kind to which its readers were unaccustomed. It deals with a series of sections of an early human embryo, and while containing nothing that is new, surpasses all precedent in being illustrated by 11 plates of photomicrographic figures which do not portray a single fresh fact and can only be defined as useless. When, further, it is observed that the paper (by an English author) which immediately followed this in order of publication was similarly granted 12 plates, where 4 might well have sufficed, there is no wonder that there arose in the minds of the supporters of the journal a misgiving, lest the new association might perhaps lead to disaster. Let it be said, however, that American papers since received have been of a more normal kind.

This consideration lends interest to the circumstance that in the journal under review one of the five papers submitted monopolises 37 of the 98 pp. which make up the issue, as well as the whole of the 9 plates and 27 of the 42 text figures. It deals with a series of human embryos, as illustrating "The Development of the Limbs, Body-wall, and Back, in Man," and is a joint production by Drs. C. R. Barden and W. H. Lewis, of Baltimore. It is carefully written, and of the illustrations no praise can be too high. But we deplore the fact that, beyond the more exact determination of the actual period at which some of the important constituents of the developing nervous system and parts of the fore- and hind-limbs are first differentiated, there is nothing either recorded or delineated in it which is new. As a chapter for a text-book it would be well-nigh ideal; but in a journal devoted to records of research and new observations it is out of place and does but hamper the way.

We wish no disrespect to the authors, for if, as we assume, in providing the positively magnificent illustrations, they have but availed themselves of the condition set forth in the editorial advertisement, "that the cost of more expensive plates must be borne in part by the authors," we would rather tender them our hearty thanks. While, however, we would thus appraise their enterprise and artistic taste, we are still of opinion that, if our surmise is correct, both these and their enthusiasm have been misapplied; for if we are to proceed on these lines, the danger, at present obvious enough in all departments of anatomical

inquiry, of the science becoming buried in its own literature will be rendered unavoidable. Of the other papers which fill the remaining 61 pp. of the issue before us there are four. One by Dr Preston Kyes, of Chicago, on "The Intralobular Framework of the Human Spleen," contains little that is new, and is chiefly noteworthy for the introduction of a method. Then follows a paper entitled "Studies on the Neuroglia," by Dr. Carl Huber, of Michigan, which embodies a useful *résumé* of the conflicting results of the observations of previous investigators. The author has adopted the comparative method of inquiry, and has done good service in relation to technique; and among his chief results is the conclusion that certain of the neuroglia fibres are not simply processes of the cells, or, as von Kölliker believed, of a differentiated cell-plate, but that they are to be regarded as intercellular.

The fourth paper is welcome, as dealing, in an up-to-date manner, with the modern topic of "The Normal Histology of the Human Hæmolymph Glands." Its author, Dr. A. S. Warthin, also of Michigan, gives it as his opinion that our conceptions of lymphoidal tissues are greatly broadened by the study of these glands. He distinguishes between "spleenolymph" and "marrowlymph" glands, on a basis of structural and functional differentiation. He defines the latter as retroperitoneal, and in many observed cases most prominent when associated with pathological conditions. He admits the existence of transitional types of gland, and suggests that the ordinary lymphatic gland is the most highly developed, and that the spleen stands in similar relationship to it through the spleenolymph gland as does the lymphoid marrow through the marrowlymph gland. He further regards the red marrow as "the most primitive type of lymphoid structure."

The fifth and last paper is by Prof. C. S. Minot, of Harvard Medical School, who needs no introduction to English anatomists. It is "On the Morphology of the Pineal Region, based upon its Development in Acanthias," and is a very careful study, mainly of the paraphysis and velum. Six "fundamental morphological divisions" are recognised "in the median line of the diencephalic roof," and for some of these new terms are proposed. It is pointed out, on a delimitation of that which the author terms the "paraphysial arch," as distinct from the "post velar," that the posterior commissure belongs morphologically to the mid-brain. The paraphysis is regarded as in all probability a true gland, akin to the infundibular gland and the glandular epiphysis of birds; and it is suggested that these are severally comparable to ductless glands, and that they "supply some substances which are useful to the nervous system."

The journal is well supported, and its get-up is deserving of the highest praise. Its collaborators include the names of more than sixty persons, most of whom are either leaders in human and comparative anatomy in the United States or otherwise well known, and its editorial board is composed of eight of their number who are sufficiently representative. On the whole, we would congratulate our friends upon their venture; and if they will only see to it that, whenever possible, they rest content to work upon a basis of the bare record of facts hitherto unobserved, whereby they will not burden an already overcrowded literature, we can at least assure them of our sympathy and good wishes, if not our actual support.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

LORD Strathcona, the Lord Rector of the University of Aberdeen, has sent a cheque for 25,000*l.* towards the Aberdeen University building scheme, the public having subscribed 30,000*l.* and thereby more than fulfilled the condition under which Lord Strathcona promised his gift.

THE Prince of Wales has consented to visit Manchester on March 12 to open the Whitworth Hall at the Owens College. At a meeting of the Court of Governors of the College on Tuesday, the following motion was passed:—"That the time has arrived when steps should be taken to secure that there should be, as originally proposed by the Owens College, an independent University in Manchester."

THE annual meeting of the Geographical Association will be held at the College of Preceptors on Wednesday, January 15. Mr. Douglas W. Freshfield, president of the Association, will occupy the chair, and an address will be delivered by the Right Hon. James Bryce, M.P., on "The Importance of Geography in Education." Tickets may be had on application to the hon. sec., Dr. A. J. Herbertson, 9, Staverton Road, Oxford, or to the hon. treas., Mr. J. S. Masterman, St. Margaret's, Dorking.

THE system of teaching by correspondence is not one which has attained to very great favour in this country, except, perhaps, as a means of preparing for examinations, and it would be considered by most especially unsuitable for studying such preeminently practical professions as civil, mechanical and electrical engineering, mining, &c. Yet it appears from an article in a recent number of the New York *Electrical Review* that this system has a considerable vogue in America. The International Correspondence Schools, in spite of the fact that they were only inaugurated ten years ago, now number more than 350,000 students, amongst whom a large proportion are following courses in engineering, and it is not the only institution of the kind in the States. A decidedly valuable feature of the system in the case of the electrical courses is that students are supplied with sufficient apparatus to carry out most of the fundamental experiments. No doubt this method of teaching can be of great benefit to those who are actually employed in engineering works and are thus more or less conversant with the practical side of the subject, and in consequence can be of considerable help in raising the efficiency of the country, which must ultimately depend on the efficiency of its workers.

A PAPER on German Technical Schools by Prof. V. C. Alderson, Dean of the Armour Institute of Technology, published in the *Chicago Inter Ocean*, contains some points which serve to accentuate the account given in last week's notes (p. 213) of the little that is being done for higher technical education in Great Britain. Prof. Alderson describes briefly the Technical High Schools at Charlottenburg, Karlsruhe, Munich, Hanover, Darmstadt and other German cities, and compares the work carried on in them with that of the technical schools in the United States and Great Britain. He points out as a lamentable fact that the provision for engineering education in London is totally inadequate. "In this great city of 6,000,000 people barely 600 students a year are provided with engineering instruction of an advanced character. In this great metropolis, which contains more engineers of every class than any other city in the world, and where there is the greatest demand for their services, not only at home, but in foreign enterprises financed in London, the provision for their education is comparatively nothing. Any one of the German Technische Hochschulen which I have described, with far less reason for existence, has a larger equipment, is more expensive to maintain, covers a broader field of work, and is better fitted to exert a powerful influence upon the profession and the industries than the best technical school in London. Not only are the few schools now in the field inadequate for the purpose, but many fields of engineering education are entirely bare. Absolutely no provision is made for teaching marine engineering, naval architecture, railway engineering, municipal engineering, or architecture. These are departments of the utmost consequence for the continued prosperity of London, yet she allows her young men to pick up their training in the old-fashioned way, and if she needs a really capable man she must import him from Germany, Switzerland or America. London has received no greater shock recently than to wake up and find that the equipment of the new 'twopenny tube,' as the Electric Railway is called, was almost entirely American. The error which Englishmen make in this whole field of technical education is a failure to recognise the difference between the skilled workman and the professional engineer. She has been endeavouring to compete with the highly trained scientific experts of Germany and America by simply educating the hand, training artisans in the belief that she was making professional engineers. Not until England is dotted with large and flourishing schools like the Central Technical College of London, not until the English realise the necessity of training both the hand and the head, and not until she perceives the full value of high-grade engineering education will she be safe from the intrusion of German and American engineers who have had a thorough engineering training." This view from outside confirms that which can be seen when our educational structure is examined from within, and supplies a further reason for increased scientific training for leaders of industry.

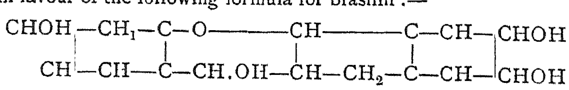
SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, December 19, 1901.—Prof. Emerson Reynolds, president, in the chair.—It was announced that the remaining meetings of the present session would be held alternately on Thursdays at 8 p.m. and Wednesdays at 5.30 p.m., commencing with an evening meeting on Thursday, January 16. The text of the address of congratulation to M. Berthelot was then read, and the secretary recorded the presentation of a plaster cast of the bronze portrait of Bunsen from the tomb at Heidelberg by Sir Henry Roscoe, and of a photograph of a bas-relief of Prof. Julius Thomsen by Mr. H. Faber.—The following papers were read:—(1) The constitution of corydaline, (2) the relations of corydaline to berberine, by Dr. J. J. Dobbie and Mr. A. Lauder. The authors have studied exhaustively the action of various oxidising agents, such as potassium permanganate and dilute nitric acid, upon corydaline, an alkaloid derived from the Tyrolean plant *Corydalis cava*, and by the identification of the ultimate oxidation products have established the fact that it is closely related to the yellow alkaloid berberine, and have therefore assigned to it a constitutional formula of the type suggested by Perkin for the latter alkaloid. The interrelations of the two alkaloids are shown in the following scheme:—

Corydaline (colourless) $C_{22}H_{27}NO_4$	by *oxidation* gives	dehydrocorydaline (yellow) $C_{22}H_{23}NO_4$.
Berberine (yellow) $C_{20}H_{17}NO_4$	by *reduction* gives	tetrahydroberberine (colourless) $C_{20}H_{21}NO_4$.

The constant difference C_2H_6 observed in the corresponding alkaloids of the scheme is accounted for by the presence of a methyl group in the α position of the pyridine ring and the occurrence of two contiguous methoxyls in place of the piperonyl group of the berberine formula of Perkin.—The magnetic rotation of some polyhydric alcohols, hexoses and disaccharoses, by Dr. W. H. Perkin, sen. The phenomena of varying specific rotation shown by solutions of sugars have been explained by the assumptions that these substances in the solid form possessed a structure which became modified gradually in their aqueous solutions, or that the solid was made up of complex molecules which underwent simplification in the presence of a solvent, or that solution was accompanied by gradual hydration. The magnetic rotations of solutions of the various sugars show that the first of these hypotheses is probably the correct one, and incidentally it was found that the observed values for dextrose agreed best with those calculated for Tollens' formula, which represents that substance as similarly constituted to ethylene oxide.—Stereoisomeric halogen derivatives of α-benzoylcamphor, by Dr. M. O. Forster and Miss F. M. G. Micklethwait. α'-Benzoyl-α-bromocamphor and α-benzoyl-α'-bromocamphor were prepared and characterised; the former has the specific rotation $-10°$ in benzene, the latter under the same conditions $-53°$. The corresponding chloro-derivatives have respectively the rotations $-27°$ and $+26°$ in chloroform.—Brasilin and hæmatoxylin, by Prof. W. H. Perkin, jun. These closely related substances are the characteristic colouring matters respectively of Brazil wood and logwood. As the result of a long-continued investigation in conjunction with his pupils, the author had suggested two formulæ which might equally well represent the constitution of hæmatoxylin, and the present paper gives conclusive evidence in favour of the following formula for brasilin:—



hæmatoxylin being hydroxybrasilin with the —OH in the position 1.—Is argon an elementary substance? by Mr. G. Martin. The view is put forward that since argon furnishes no characteristic series of compounds it may be regarded as a mixture of elementary gases.—The action of phosphorus trithiocyanate on alcohol, by Dr. A. E. Dixon. In this reaction thiocyanic acid is formed together with isopersulphocyanic acid, but no substance of the formula $C_8H_{18}N_4S_4O$, as found by Lössner, could be obtained.—The influence of salts and other substances on the vapour pressure of aqueous ammonia solutions, by Dr. E. P. Perman. Alkali salts produce an increase of pressure, while the formation of complex substances with copper salts reduces it.—The action of sodium hypochlorite on benzenesulphoanilide, by Dr. J. B. Cohen and Mr. J. T. Thompson. Benzenesulphonyl-p-chloranilide is the principal product of this reaction, and has been obtained in a pure state and characterised.—The relationship between the substitution and constitution of benzeneazo-α-naphthol, by Dr. J. T. Hewitt and Mr. S. J. M. Auld. This substance is regarded as an oxyazo-compound, since on acetylation and complete decomposition it furnishes aniline, but not acetanilide, and by reduction gives rise to a hydrazo-derivative. The monobrombenzeneazo-α-naphthol behaves similarly, the substitution occurring in the naphthol nucleus.

Geological Society, December 18, 1901.—Mr. J. J. H. Teall, V.P.R.S., president, in the chair.—Prof. H. G. Seeley drew attention to a skull of *Equus fossilis* from Keswick, exhibited by Mr. J. Postlethwaite, and said that it belonged to a species of horse, but the skull appeared to be broader and flatter in front of the orbits than in the *Equus caballus*; and it gave evidence on the upper surface of being an aged specimen, an inference which was supported by the palatal conditions. Mr. Postlethwaite said that the skull was found beneath the floor of one of the rooms of a farm-house about six miles east of Keswick. The house, which is of considerable age, was being altered and repaired, and it was in taking up one of the floors, for the purpose of relaying, that the skull was found. The surface-deposit on the farm is Glacial Drift.—Prof. W. W. Watts called attention to the exhibited set of twenty-two photographs, the first of three sets to be published as typical examples of geological photographs by the committee of the British Association on geological photographs.—Coal and petroleum-deposits in European Turkey, by Lieut.-Colonel Thomas English. In this paper an account is given of the formations which include some recently discovered coal-seams and naphtha-bearing sands of Tertiary age in the little visited stretch of country lying to the north of the Gulf of Xeros in the Mediterranean, and of the western portion of the Sea of Marmora.—On the geological and physical development of Dominica; with notes on Martinique, St. Lucia, St. Vincent and the Grenadines," by Prof. J. W. W. Spencer. These islands form a continuation of the volcanic chain extending from Gaudeloupe, though separated one from the other by embayments in the submarine plateau, reaching to depths of more than 6000 feet, within the line connecting the shores of the islands. These submarine valleys head in cirques, like the amphitheatres which occur on the slopes descending from high plateaux. From the ends of the cirques, valley-like channels can be traced landward on the submerged plateaux, or can be found to cross them in order to join like features on the other side. The cols between the opposite valleys vary in depth from about 2000 to 3600 feet, except that between the Grenadines and the Trinidad banks, where the divide may not be more than 750 feet below the surface of the sea, and one south of St. Vincent (less than 1300 feet). Some of the submarine channels have remarkable tributaries. The drowned valleys, like those about the islands to the north, assume two very different forms—those with broad undulating outlines, such as characterise the features produced during the long Miocene-Pliocene period of erosion, when the surfaces of the land were at or near the base-level of erosion, and other types where very deep valleys and gorges incise the more rounded features of the drowned plateau, which in the early Pleistocene epoch thus appears to have stood for a limited time at an altitude of 6000 or 7000 feet, as shown within the limits of the Antillean mass (and still higher from evidence beyond). There are no coastal plains, strictly speaking; only to a very limited extent are the islands surrounded by shelves submerged to a depth of less than 200 feet. But the Grenadine banks are extensive. One or two outlying remnants of the Antillean plateau occur south-east of Dominica, and another about sixty miles east of Martinique, all of which may be fragments of the old coastal plains. All the islands are underlaid by old Tertiary or pre-Tertiary igneous rocks—On the geological and physical development of Barbados, with notes on Trinidad, by Prof. J. W. W. Spencer. Barbados, more than 100 miles east of the main chain of islands, is a remnant of the dismembered and sunken Antillean plateau, with the embayment in it, west of the island, reaching to a depth of more than 7000 feet. But the drowned Barbados ridge extends far, both to the south and to the north of the island, and is connected by another ridge with the Martinique mass. Trinidad is part of the South American continent, being on the subcoastal shelf which extends much

farther seaward. Trinidad has more continental features than the other islands. Its surface-topography has been found to owe its origin to the erosion features of the Miocene-Pliocene period, which have been covered by only thin mantles as in Barbados, so that its life-history falls into harmony with that of the other islands. In its older beds it has the deep oceanic oozes as in Barbados. No volcanic phenomena have been added to the features of these islands.

Royal Microscopical Society, December 18, 1901.—Mr. William Carruthers, F.R.S., president, in the chair.—Messrs. R. and J. Beck exhibited a new micrometer microscope, the body of which was made to traverse across a long stage by means of a fine screw, the milled head of which was divided so as to indicate a movement of 1/100 millimetre. The body could also be placed in a horizontal position, when it could be used as a telescope to measure distant objects.—Mr. F. W. Watson Baker exhibited a number of microscopic specimens illustrating the development and structure of eyes. They were shown under twenty microscopes and were the most perfect sections which could be obtained from the best preparers in this country and abroad.—Mr. Nelson sent three notes which in his absence were read by the secretary. The first was a description of Holtzapffel's microscope. The date of it is 1830 and in it are found four original devices, (1) the clamp foot for clamping the instrument to the edge of a table, predating a similar device of Varley's in 1831; (2) the back of the mirror is flat polished brass so that monochromatic light may be reflected by it; (3) the stage is focussed by an excentric which differs from and predates the somewhat analogous devices of Pacini and Plössl; (4) the movement of the lens holder by means of a steel tape and pinion. The second note was a description of the first English achromatic objective, made by W. Tulley. It was a triplet and was made at the suggestion of Dr. C. R. Goring, who paid 90*l*. for it. The focus of the combination is 0·933 inch, initial magnifying power 10·72, N.A. ·259, and the O.I. the large amount of 24·2. Mr. Nelson then described the Chevalier-Euler achromatic objectives of 1823–24 and 1824–25. These were doublets, and in 1827 Mr. J. J. Lister put one of the Chevalier doublets as a front and a Tulley's triplet as a back lens. The focus of the combination was 0·52 inch and it was the finest microscopic objective that had up to that time been produced, and was, strictly speaking, the first really successful scientific microscopic objective. Lister's labours in perfecting objectives and the great use they had been to the leading opticians of the day were referred to. The third note was on a useful caliper gauge. It can be purchased at any watchmaker's tool shop for three or four shillings. It is convenient for measuring the thickness of cover glasses, and for low-power work the scale may be placed on the stage of a microscope and the constant of an eye-piece micrometer found by comparison with the mm. divisions.—The president gave an account of some investigations which he had made in reference to a disease that had caused great mischief in the cherry orchards in Kent. About fourteen months ago, when his attention was first directed to it, the disease was prevalent over a considerable area, a noticeable feature in connection with it being the persistence in the autumn of the dead leaves on the branches, instead of their falling off, as they would if the trees were healthy. The leaves of affected trees were pervaded by the mycelium of a fungus which destroyed them, and as the food of the tree was prepared by the leaves, the growth of the tree would, as a consequence, be arrested. The results of experiments in the cultivation of the fungus showed it to be one which belonged to the genus Gnomonia. Many of the fungi in this class passed through various stages in their life-history, for example, the mildew on wheat, which was first developed on the berberry and then spread to the wheat, appearing first as rust and afterwards as mildew from the same mycelium. The president referred to the absence in this country of any authority competent to investigate cases such as this; on the continent, however, the Governments had taken up the matter, and the experts who had inquired into it had found that to check the spread of the disease it was necessary to collect all the dead leaves and burn them. The president had consequently urged upon the fruit growers the necessity of following this recommendation, but had only been able to persuade two growers to do so; both of these, however, had found it to be thoroughly effective. Prof. A. W. Bennett in his remarks enlarged upon the absence in this country of investigations into such matters by State-paid establishments, and described what was being done in the United States, where every State had its own experimental station.

PARIS.

Acadamy of Sciences, December 30, 1901.—M. Fouqué in the chair.—M. Albert Gaudry was elected vice-president for the year 1902.—On double fertilisation in the Solanaceæ and Gentianaceæ, by M. L. Guignard. A study of *Nicotiana tabacum* and *Datura loevis* in the Solanaceæ and of *Gentiana ciliata* shows that double fertilisation is effected in both of these orders in essentially the same manner as in other cases which have been observed.—On a series of factorials, by M. Niels Nielson.—On linear differential equations which are of the same species, by M. Alfred Lœwy.—Some new theorems on entire functions, by M. Ernst Lindelöf.—On integral invariants and differential parameters, by M. Alf. Guldberg.—Internal tensions produced by two equal directly opposed forces acting on an indefinite solid, by M. Mesnager.—The critical constants and molecular complexity of some hydrocarbons, by MM. Ph. A. Guye and Ed. Mallet. The critical pressures and temperatures are given for durene, naphthalene, diphenylmethane and diphenyl. From these are calculated the critical coefficients, the constants a and b in Van der Waals' formula and the ratios of the real critical density to the theoretical. The conclusion is drawn that none of the hydrocarbons studied are associated at the critical point.—The extension of Kirchhoff's laws, by M. E. Carvallo. The results of this investigation are expressed as follows: The flux of the total current through the whole of a closed surface is zero, and the total electromotive force which rules in a closed circuit is zero.—On a new reaction between electrostatic tubes and insulators, by M. W. de Nicolaiève.—The action of high-frequency currents upon animals, by MM. H. Bordier and Lecomte. It has been shown that high-frequency currents can be applied directly to man without any sensation being produced, in spite of the large amount of energy which can be thus transmitted. It has been suggested as an explanation of the absence of sensation that the currents pass over the surface of the body without penetrating it. The experiments of the author negative this view, as such currents were found to be fatal to the rabbit, guinea-pig and rat.—Remarks on the preceding communication, by M. d'Arsonval. The facts described by MM. Bordier and Lecomte are in full accord with previous observations of the author. Stress is laid upon the conditions which must be observed in studying high-frequency currents. It is necessary to avoid all action on the sensibility, muscular contraction, and all abnormal elevation of temperature.—On the existence of rays capable of reflection in the radiation emitted by a mixture of the chlorides of radium and barium, by M. Th. Tommasina.—On the electro-capillary maxima of some organic compounds, by M. Gouy.—The heat of formation of the hydrate of chlorine, by M. de Forcrand. The number deduced from the dissociation curves of Isambert, Roozeboom and Le Chatelier is 18·16 calories; the value obtained from direct experiment is 18·57.—On the determining causes of the formation of the visual organs, by M. Antoine Pizon. The phenomenon of vision is regarded simply as a consequence of the accumulation of pigmentary granules at certain points of the body, and of the absorbing power of these granules for light rays. These views are regarded as affording an explanation of the occurrence of the eyes in the regions of greatest illumination, the position of the cephalic eyes, the extraordinary number of eyes in certain annelids, the more or less complete disappearance of the eyes in species inhabiting caves and in internal parasites.—The leaf trace in ferns, by MM. C. E. Bertrand and F. Cornaille.—On the eclogites of the Aiguilles Rouges, by M. Étienne Joukowsky.—On ergot of rye, by M. Marcel Guédras. The therapeutic action of this drug is due to sphacelinic acid and to cornutine. These active principles cannot be separated practically, since they have nearly the same solubility.

NEW SOUTH WALES.

Linnean Society, November 27, 1901.—Prof. J. T. Wilson in the chair.—The following papers were read:—Descriptions of new genera and species of Australian Lepidoptera, by Mr. Oswald B. Lower. Sixty-seven species referable to six families, namely, Arctiadæ 2, Noctuidæ 39, Thyrididæ 1, Pyralidæ 23, Tortricidæ 1, Plutellidæ 1.—The deterioration of raw and refined sugar crystals in bulk, by Mr. R. Greig Smith. The deterioration of bulk crystals is in many cases caused by *Bac. levaniformans*,

which was separated from many samples of inverting sugar. The conditions necessary for the degradation are a moist state of the sugar and a warm temperature. The formation of gum levan is in abeyance, probably on account of the infinitesimal amount of nitrogenous food. The bacillus is widely distributed, having been found in beet crystals from France and Germany and in cane sugar from Java, Egypt and Australia.—The acid fermentation of raw sugar crystals, by Mr. R. Greig Smith. *Bac. levaniformans* may set up an acid fermentation whereupon the sugar smells strongly of acetic and butyric acids.—Notes on the botany of the interior of New South Wales, part v., by Mr. R. H. Cambage. The conspicuous vegetation of the country around the Lachlan River, extending from Parkes to Marsden, is dealt with.—Studies in Australian entomology, No. xi. Description of a new ground-beetle from Victoria, by Mr. Thomas G. Sloane. The insect here described is a species of Morphnos, easily distinguished from the only other member of the genus, *M. flindersi*.—On the skeleton of the snout and os caruncula of the mammary fœtus of monotremes, by Prof. J. T. Wilson.—The protoconchs of some Port Jackson gasteropods, by Mr. H. Leighton Kesteven.—Studies on Australian Mollusca, part v., by Mr. C. Hedley. Several land shells hitherto unfigured, collected by the Chevert Expedition, are herein illustrated.

ST. LOUIS.

Academy of Science, December 2, 1901.—Mr. J. Arthur Harris presented in abstract a paper on normal and teratological thorns of *Gleditschia triacanthos*, L.—Prof. A. S. Chessin, of Washington University, delivered an address on the harmony of tone and colour. The speaker said that although the idea is not new that colours, like tones, are subject to laws of harmony, he did not know that any systematic theory concerning this had thus far been presented, and the object of the paper was to establish such a theory. A colour-scale was constructed, and the properties of the intervals corresponding to those appearing in the musical scale were discussed, and the conclusion was reached that within the limit of an octave the laws of harmony in tone and colour are identical.—A paper by Prof. A. S. Chessin, on the true potential of the force of gravity, was presented and read by title, the author remarking that this was the first of a series of detailed papers bearing upon the general subject, the broad conclusions concerning which he had presented in synopsis at a recent meeting of the Academy.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 9.

MATHEMATICAL SOCIETY, at 5.30.—Non-uniform Convergence, and the Integration of Series: the President.—Network: S. Roberts, F.R.S.—On Quartic Curves with a Triple Point: A. B. Basset, F.R.S.—On the Integrals of the Differential Equation

$$\frac{du}{\sqrt{f(u)}}+\frac{dv}{\sqrt{f(v)}}=0,$$

where $f(x)\equiv ax^4+4bx^3+6cx^2+4dx+e$, Considered Geometrically: Prof. W. Snow Burnside.—On the Fundamental Theorem of Differential Equations: W. H. Young.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Discussion of the Technical Reports on the Institution Visit to Germany, 1901, by the Committees on Traction, Light and Power; Manufacturing, and Telegraphs and Telephones.

FRIDAY, JANUARY 10.

ROYAL ASTRONOMICAL SOCIETY, at 5.—The Attraction of the Himalaya Mountains upon the Plumb-line in India: Major S. G. Burrard.—The Period and Light Curve of the Variable Star 6685 Y Lyræ: A. Stanley Williams.—Note on a Further Attempt to observe the Corona without an Eclipse: Rev. C. D. P. Davies.—The Double Star Σ 1639 Comæ Berenicis: Thomas Lewis.

MALACOLOGICAL SOCIETY, at 8.

MONDAY, JANUARY 13.

SOCIETY OF ARTS, at 8.—The Purification and Sterilisation of Water: Dr. Samuel Rideal.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—From Shanghai to Bhamo: Dr. R. Logan Jack.

TUESDAY, JANUARY 14.

ROYAL INSTITUTION, at 3.—The Cell: Prof. A. Macfadyen.

ZOOLOGICAL SOCIETY, at 8.30.—Observations on some Mimetic Insects and Spiders from Borneo and Singapore: R. Shelford.—On Variation in the Number and Arrangement of the Male Genital Apertures in *Nephrops norvegicus*: F. H. A. Marshall.—On some Remarkable Digestive Adaptations in Diprotodont Marsupials: Dr. Einar Lönnberg.

INSTITUTION OF CIVIL ENGINEERS, at 8.—American Workshop Methods in Steel Construction: H. B. Molesworth.

WEDNESDAY, JANUARY 15.

SOCIETY OF ARTS, at 8.—Elliptographs: Frank J. Gray.

ENTOMOLOGICAL SOCIETY, at 8.—Annual Meeting.

ROYAL METEOROLOGICAL SOCIETY, at 7.45.—Annual General Meeting.—Address on The Element of Chance in relation to various Meteorological Problems: W. H. Dines, President.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Annual Meeting.—Address by the President.

GEOGRAPHICAL ASSOCIATION, at 3.—Annual Meeting.—Address on The Importance of Geography in Education: Right Hon. James Bryce, M.P.

THURSDAY, JANUARY 16.

LINNEAN SOCIETY, at 8.—On the Use of Linnean Specific Names: H. and J. Groves.—Exhibitions: Branches of Cherry affected by the Gnomonia Disease, with Remarks on its Effects and Climatic Causes: A. O. Walker.—Photographs and Specimens of Heads of Wild Sheep, to Illustrate a recent Suggestion as to the Use of Large Horns in Feral Species: J. E. Harting.

CHEMICAL SOCIETY, at 8.—Myricetin, Part II.: A. G. Perkin.—The Colouring Matters of Green Ebony: A. G. Perkin and S. H. C. Briggs.—An Investigation of the Radioactive Emanation produced by Thorium Compounds, I.: E. Rutherford and F. Soddy.

FRIDAY, JANUARY 17.

ROYAL INSTITUTION, at 9.—Interference of Sound: Lord Rayleigh.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Theory of Heat-Engines: Captain H. Riall Sankey.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Modern Machine Methods: H. F. L. Orcutt.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

PSYCHOLOGY OF LANGUAGE.

Völkerpsychologie. By W. Wundt. Erster Band. Die Sprache. 2 Parts. Pp. xv+627 and x+644. (Leipzig: Engelmann, 1900.) Prices 14*s.* net and 15*s.* net.

PROF. WUNDT'S two bulky volumes form the first part of a long-expected treatise on race-psychology. The distinguished author has not the gift of concise utterance, and one almost shudders to think of the thousands of pages to which the work promises to extend by the time the second and third parts, dealing with myth and custom, have been completed. It is, perhaps, unfortunate that Prof. Wundt should have determined to treat his two remaining topics in the order just indicated; if there is anything at all in the results and methods of modern anthropology, it is from customs of the most practical kind, in fact from magic, that mythology on the whole derives its existence; hence one would think that custom rather than myth is entitled to the central position in a systematic "Völkerpsychologie." Can it be that Prof. Wundt's arrangement of his material has been unconsciously influenced by the now obsolete or obsolescent view of mythology as a "disease of language"? In any case, the intimate connection of the myths of one age with the magic of its predecessors seems to diminish the value of the author's psychological scheme by which custom is made to correspond to the volitional, myth to the emotional, aspect of racial life (vol. i. p. 27).

No one but a specialist in comparative philology is really competent to deal minutely with Prof. Wundt's elaborate investigations into the psychology of language. In the present notice, it is impossible to do more than supply a very brief summary of the topics treated of, and a briefer indication of a few of the author's leading results. He begins with a detailed and careful description of the general characteristics of emotion and its expression, which leads up to a study of the simplest and crudest form of language, the expression of emotion by a code of gestures. The account of gesture-language, which is based upon the artificial systems of signs in use among the dumb, as well as of the wide-spread gesture-language of the North-American Indians and of the Neapolitan populace, is full and interesting, especially in dealing with the question of the existence of grammatical form in gesture-speech. That gesture-language is not formless, as is often asserted, is well shown by reference to the fixed order in which the gesticulator expresses the constituent parts of a proposition. Prof. Wundt, by the way, appears not to be acquainted with the singularly full and excellent study of the gesture-language of Australian tribes contained in Mr. W. E. Roth's "Aborigines of North-West-Central Queensland." Proceeding in his third chapter to deal with articulate sounds, the author has much that is useful, if little that is new, to say about the differences between the song of birds and the song of men, and between the song and the speech of men. Incidentally he derives human song from vocal accompaniments of the rhythmical movements of work, and therefore regards its connection with religious cultus as secondary (i., p. 265). It might, perhaps, be objected that the beginnings of both rhythmical movement and its vocal accompaniments are to be found in the corroborees of the Australians, among whom systematic work hardly exists, and that here, at all events, the rhythmical movements appear to arise directly out of the magical representations of incipient cultus. Prof. Wundt is on surer ground when he goes on to deal with the origin of onomatopœia. It is impossible to resist the arguments by which he shows that direct and intentional imitation of natural sounds can have little to do with the origin of names, and that the real process is one of impulsive and unintentional imitation by the organs of articulation of striking forms of physical movement.

The fourth chapter deals with the psychological causes of sound-change. Prof. Wundt finds the principal source of regular and continuous changes affecting whole classes of sounds, apart from such incidental influences as those of climate or racial mixture, in the growing tendency of civilised men to speed of thought and utterance. To this psychical source he traces those changes in articulation which have often been ascribed to the imaginary desire for ease of utterance; a desire which, in the first place, is never consciously operative, and, in the second, could not exist unless advance in culture brought with it tendencies which make an originally easy articulation increasingly difficult. Such tendencies we have in the increasing speed of civilised speech, with its effects upon pitch and accent. Prof. Wundt uses his theory chiefly to explain the familiar changes formulated in "Grimm's law." On the value of the explanation no doubt the philologists will claim to be heard, but it has at any rate the merit of assigning a psychological *causa vera* for facts which have often been either left entirely unaccounted for or put down to a purely imaginary "desire for ease." In the case of the sound-changes produced by assimilation, a second psychological principle is invoked, viz. the tendency of thought to outrun speech. The assimilation takes place because the second sound is already "in consciousness" before the first has been duly articulated. The same principle in combination with the laws of association is in the succeeding chapter employed to explain the various forms of paralalia. Curiously enough, the author does not treat of the important vowel-changes which occur in the life of a language, such as those by which diphthongs have been substituted in modern spoken English for so many of the original vowels. In the chapter on word-formation the sections dealing directly with the nominal subject are rather of grammatical and philological than of strictly psychological interest. The earlier parts of the chapter, on the other hand, which treats of the cerebral speech-centres, the phenomena of aphasia and the perception of short words, are of great psychological interest, but so loosely connected with the ostensible subject of the chapter that they would be more in place in a separate work on experimental and physiological psychology.

Prof. Wundt's second volume is at once far the more important half of his book and the more difficult to describe with justice in a brief notice. He has set himself the gigantic task of digesting the facts contained in such works as F. Müller's monumental "Grundriss der Sprachwissenschaft" into a systematic form, and eliciting

from them a psychological theory of the successive evolution of grammatical form and syntactical construction. This task is performed in the two chapters which deal with "word-forms" and "sentence-construction." These are followed by a chapter on the psychical causes of change of signification, and the whole work concludes with a final chapter devoted to a brief *résumé* and criticism of the various theories of the "origin of language." It is significant of the influence exerted upon modern psychological thought by the concept of evolution that this last chapter is by far the shortest in the book and that its result is in the main the purely negative one that speech, like the other human faculties, has no definite beginning or origin, but is connected by a continuous development with a pre-articulate and pre-human past, while the earliest stages of language known to us themselves presuppose a long development within human speech itself. Of the elaborate investigations which fill Prof. Wundt's chapters vi.–viii. it is impossible, for reasons of space, to say much except that they are of the highest psychological interest and importance. Specially important are the distinction between a preeminently nominal and objective type of language, like those, *e.g.*, of the American or of the Ural-Altaic family, and a pre-eminently verbal and subjective type, like that to which we are accustomed in the familiar Indo-Germanic group, and the very similar distinction, in the realm of syntax, between the attributive and predicative types of proposition as corresponding to the "nominal" or objective and the "verbal" type of thought respectively. These and similar differences, obviously pointing to marked divergence of psychological endowment, are minutely and learnedly discussed by Prof. Wundt in a way which only makes one regret that his weakness for diffuse expression makes it so difficult to get a clear and systematic grasp of his argument as a whole.

A. E. T.

ELECTRICAL ENGINEERING TESTING.

Electrical Engineering Testing. By G. D. Aspinall Parr. Pp. viii+474; 218 diagrams, 31 tables. (London: Chapman and Hall, Ltd., 1902.) Price 9*s.* net.

DURING the last few years the rapidly spreading use of electrical methods of dealing with engineering problems has been naturally accompanied by the publication of a great mass of isolated work on the testing of electrical materials and machinery. Successful design requires not merely a knowledge of principles, but an intimate acquaintance with the properties of materials to be used; that these may be used economically and without needlessly high "factors of safety." And an electrical engineer is required to understand how to test for magnetic and electrical excellence the material he may have to use, as well as how to test his machinery for efficiency and staying power and his instruments for accuracy. It is probable that electrical engineering testing presents not only a possibility of, but a necessity for, greater refinement of measurement than occurs in other branches of engineering testing; the success of much of our electrical machinery and apparatus being more immediately dependent on exact design.

When a subject is developing so rapidly as that which Mr. Parr has chosen, it is not easy to maintain an exact knowledge even of what should be regarded as the simpler matters, and it is still less easy to keep this knowledge in due proportion. For that which was but lately abstruse or useless may rapidly become clear and even elementary information.

The volume before us will prove useful to many, containing, as it does, much information relating to electrical testing which, in spite of a rather unsatisfactory arrangement, is in a fairly accessible form. Its main portion consists of accounts of about 130 different tests, each arranged as follows:—A descriptive introduction; a list of apparatus wanted; what observations to take and how to take them; and concluding with "inferences" to be drawn from the results of the test. The book is styled "a practical work," meaning, we presume, not so much a text-book in which difficulties are explained as a hand-book containing useful information about tests. It is primarily written for students, and we do not doubt it will prove very useful alike to student and demonstrator.

The "descriptive introductions" are probably as satisfactory as the nature of the book will allow. The list of apparatus, while usually complete, will strike the reader as relating in particular to the apparatus of Mr. Parr's laboratory in the Yorkshire College. The next section of each test on taking and tabulating observations is very well given. It will save the student much thought and keep him from much bungling, and will raise the quality of his work—all but the first no doubt desirable when the course must be hurried over. The "inferences" are added at the end "to make the experimenter think and reason for himself." If the test had not been so well arranged for him beforehand, or the instructions so fully given, perhaps he would have had to think for himself before the test could have been carried out. This is a matter of opinion; but we think that the book will prove more useful in evening classes than with day students.

An appendix gives in a few pages the derivation of some formulæ employed, and the book concludes with some 100 interesting pages descriptive of apparatus used. The author shows much of his own apparatus and methods, which are interesting even when they do not strike one as the best.

The book is nicely printed, but bears signs of haste in preparation. Thus most readers, when they have grasped the peculiar use of the word "inference," will be surprised, if not amused, at the following: "Inference: Does the accuracy of the above test depend upon anything in particular?" p. 17; and on p. 22, under a similar heading, "Can anything in particular be deduced from the above results?" The author spells converter with an *o* in the final syllable, and writes anti-inductive where non-inductive is meant; and slips such as series for serious, p. 154, sale for scale, p. 378, Jolly for Joly, p. 390, &c., which are not infrequent, should have disappeared in the proof.

The figures are on the whole good, and the tables at the end welcome.

The author's style is often by no means lucid, and even when the meaning is clear it does not make agreeable

reading. The book is a great contrast to the other recent English work on the same subject, by Dr. Fleming, which is both readable and interesting. But we feel that there is a place also for a book such as Mr. Parr's, in which short accounts of many specific experiments are given, and the book will be of value to engineers as well as in a teaching laboratory.

D. K. M.

BURMA.

Burma under British Rule—and Before. By John Nisbet, D.Œ.C. Two volumes. Pp. xvii + 912. (Westminster: Archibald Constable and Co., Ltd., 1901.) Price 32*s*. net.

LITTLE more than a year ago a most beautifully illustrated, interesting volume on "Burma," by Max and Bertha Ferrars, appeared, which has been most favourably received. And now we have a second work on Burma. This comparatively recent part of the empire, then, receives a full share of attention, and not the least interesting part of the business is that both Mr. Ferrars and Dr. Nisbet are retired Burma forest officers. Even a cursory glance at the books will show that these two gentlemen have become most intimately acquainted with the customs and character of the Burmese. As a matter of fact, though this has not always been admitted, there is no branch of the Indian services the members of which come into closer contact with the inhabitants away from towns, than Indian forest officers. If it is remembered that in many cases the peoples in question live in out of the way places and that many of them never see a magistrate or a judge, it will readily be acceded that the selection and training of the members of the Indian forest service should be done with special care, since the happiness of millions of ignorant people depends to a considerable extent on the tact and sympathy of these officers.

Mr. Nisbet's work is divided into two volumes. In the opening chapter of vol. i. he deals with the history of Burma from the year 2266 B.C. to 1852 A.D. It will readily be understood that this sketch, occupying twenty-five pages, can only touch lightly on the history of this interesting country, and, unfortunately, the notes appear to us by no means as well arranged as they might be. Chapter ii. describes the political and commercial relations between British India and Upper Burma during the years 1853–80, relations which were anything but cordial. Here we find the great shoe question recorded, that is to say, that the British envoy had to take off his shoes and kneel down if he wished to address the King of Burma, until we come to the massacres of some fifty members of the Royal house by King Thibaw. The existing and increasing differences are further described in Chapter iii., explaining the causes of the third Burmese war. It broke out in November 1885, resulting in the annexation of Upper Burma. Apart from the utter unreasonableness of the last two kings of Burma and the cruelty of Thibaw, French intrigues contributed most powerfully to hurry on the crisis. The last straw, however, was the difference between King Thibaw and the Bombay-Burma Trading Corporation, the latter having been fined 153,000*l*. by the former. For ourselves, we cannot conceal that we should have been better pleased if the crisis had come without this last incident.

Chapter iv. deals with the third Burmese war, which practically lasted only from November 13, 1885, till January 1, 1886; but it was followed by five years during which the pacification of the country was ultimately effected.

Chapters vi.–viii. deal with civil and military administration, law and justice under Burmese rule, and the Royal Golden City. They contain much interesting information, of which the marriage law is perhaps the most curious. There were seven kinds of wives, of which four could not be divorced, but there was no difficulty in getting separated from any of the other three kinds.

Chapter ix. gives a rapid survey of "The British System of Administration in Burma." It shows how an orderly administration has been established in a comparatively short time as regards the organisation of the civil authorities, law, military and police, public works, forests, education and revenue. Of special interest is the development of the latter, it having risen from 2,415,000*l*. in 1886–87 to 5,242,000*l*. in 1899–1900, while the surplus has, during the same period, risen from 637,000*l*. to 1,821,000*l*. It is shown that Burma has already more than repaid all the outlay upon it during and since the third Burmese war. The net revenue includes a sum of 400,000*l*. derived from the teak and other forests, and this sum is capable of a further great increase.

Chapters x. to xiv. give a detailed account of the various branches of administration, such as the land tenure, settlements, agricultural and rural customs, minor rural industries (such as sifting for gold dust, silk weaving, dyes and dye-stuffs, pottery, fisheries, collection of wood-oil, preparing and transport of timber, cutch boiling, manufacture of cheroots, &c.); the mineral resources (coal, petroleum, tin, silver, lead, gold, jade, rubies); trade and commerce (the sea-borne trade of Burma in 1888–89 amounted to a value of 11,717,000*l*.; in 1899–1900 it had risen to 20,820,000*l*.)

The second volume opens with a chapter on Britain and France in further India and south-western China, and is followed by others on railway extensions; Burma's forest wealth and the importance of maintaining and increasing the production of teak timber; Burmese Buddhism; beliefs and superstitions; national habits and customs; the social system; national festivals and amusements; science and art among the Burmese; language and literature; folklore; archæology and the hill tribes.

It would be beyond the scope of this notice to go into the details of all these matters, but attention may be drawn to two points: As regards railways, Dr. Nisbet points out that the most pressing need is to develop internal communication before connections with the outside are established. When the time and money for the latter have become available it will be well, in the first instance, to connect Burma with India *via* Assam (or Arakan and Chittagong), then with Siam, leaving any possible connection with China, by way of Yunnan, for discussion in the future. Although we agree with this

view, it may happen that events in China will upset it, and that a connecting link between Burma and Yunnan by means of a railway may become a necessity.

The second point to which we desire to draw attention is the chapter on Burma's forest wealth. It is but natural that this is treated in a very full way, and we recommend its perusal to those who have up to date been hostile to forest conservancy in India and Burma. More especially Dr. Nisbet describes in full detail the great pains which are taken in ascertaining the full extent of existing rights and privileges, and the minuteness with which the requirements of the local population are provided, before any forest tract is declared a permanent State forest.

On the whole Dr. Nisbet's work may be called a very storehouse of information on Burma, to collect which must have taken him many years. If we were to find any faults with the work they would be that the author's facile pen has led him into too great a length, and that there are numerous repetitions in it. Still, those who have leisure to read the two handsome volumes will be richly rewarded for their trouble. They will find in it, not only a minute description of an interesting people, but also a record of the admirable manner in which civilised methods of administration have been successfully introduced in this far-away country in a remarkably short space of time.

OUR BOOK SHELF.

The Birds of South Africa. By A. C. Stark, completed by W. L. Sclater. Vol. ii. Illustrated. Pp. xiv+324. (London: Porter, 1901.) Price 21*s*. net.

IN a review of the first volume of this work (part of the "Fauna of South Africa"), published in our columns soon after its appearance, reference was made to the tragic death of its author, Dr. Stark, in Ladysmith, at the commencement of the siege. The first volume was practically completed by the author before his death; but of its successor the manuscript was left (partly stored at Durban and partly at Ladysmith) in a state which rendered necessary a considerable amount of revision and addition on the part of whoever undertook the task of editing and preparing it for press. By desire of Dr. Stark's executors this labour was entrusted to Mr. W. L. Sclater, the editor of the series to which the volume belongs, who is to be congratulated on having carried out so successfully an undertaking of no ordinary difficulty. For, as all those who have tried it are well aware, the completion of another man's unfinished work is often a more difficult task than to write a volume *de novo*. As this volume may be regarded as in some respects a memorial of the lamented author, his portrait is very appropriately introduced as a frontispiece.

Since the general plan of the work was somewhat fully referred to in our previous notice, and as in this respect the present volume agrees in all essential points with its predecessor, nothing need be added on the present occasion. This volume continues the description of the perching-birds, taking up the thread at the shrikes, and ending with the swallows and pittas, so that the African representatives of five families are discussed. The editor has been fortunate in again securing the services of Mr. H. Grönvold as artist; and, needless to say, the illustrations are exquisitely drawn, and at the same time true to nature. Attention may be especially directed to the figure of puff-birds and their nest, which is based on a photograph taken near Grahamstown, and forms a charming bit of bird-life. One illustration alone—that of rock-thrushes and their nest, on p. 182—has been reproduced direct from a photograph. A comparison of this with the above-mentioned picture by Mr. Grönvold leaves little doubt where the superiority lies. In addition to the text-figures this volume contains a map which should prove of much value to the students of the South African fauna.

While congratulating Mr. Sclater on the completion of this much of his arduous task, we may take the opportunity of mentioning that, with the help of Dr. Stark's note-books and papers he hopes ere long to bring out the two remaining volumes of the "Birds of South Africa." R. L.

Elementary Telephotography. By Ernest Marriage. Pp. xxix + 117. (London: Iliffe and Sons, Ltd., 1901.)

THE telephotographic lens is becoming more generally used every day, so that the publication of a good elementary treatise on the chief advantages of its employment and on its successful manipulation will be received with favour. The opening chapters describe, in simple and clear language, backed up with excellent illustrations, the optical arrangements of telephotographic lenses, the different types of such lenses, the work for which they are specially adapted, and the form of camera and accessories that experience has shown to be the most satisfactory. The author lays great stress on the importance of rigidity in both the camera and support, so the beginner should take special note of this fundamental consideration.

After a chapter on the general applications of telephotography, the author gives the beginner some excellent advice in separate chapters on the special branches of the subject, namely, architecture, portraiture and the telephotography of animals, illustrating the chief points with reproductions from photographs.

Last, but by no means least in importance, are two chapters on exposure and development and useful tables. In the former it is shown, among other things, that with a little trouble the most difficult part of the whole manipulation, namely, "correct exposure of the negative," may be successfully overcome by a simple calculation, this method being rendered more practicable and easy by the use of the tables given in the latter chapter.

It may be mentioned in conclusion that the book is neatly printed on good stout paper and the illustrations are well reproduced, so that with these extra points in its favour it will form a useful addition to photographic literature.

The British Journal Photographic Almanac, 1902. Edited by Thomas Bedding. Pp. 1560. (London: Henry Greenwood and Co., 1901.) Price 1*s*.

THE forty-first yearly issue of this almanac is well up to the standard of former years, and contains a mine of useful information for both the amateur and the professional photographer.

Among the principal contents we notice an interesting, and what should prove a useful, article on "Introductory Notes on Tele-photography," by the editor, which brings together the more important facts on the subject. This is followed by a series of short contributions on practical subjects by prominent photographers, by numerous notes and suggestions of the year, and by an epitome of the advances made in 1901. The almanac portion of the volume and tables will be found as useful as ever, and the reader will find the collection of photographic formulæ and recipes, list of photographic societies, and other miscellaneous tables and information very complete.

In addition to the 600 pages of text, those devoted

to advertisements have also their interesting features, and the numerous illustrations and process plates scattered here and there add an additional attraction to the volume. The success of this present edition will be gathered from the fact that it has already been sold right out, as is stated by the *British Journal of Photography*.

Encyclopédie Scientifique des Aide-Mémoire. Le Vin. Par Henri Astruc. Pp. 208. (Paris : Gauthier-Villars, 1901.) Price 3·0 F.

THIS little treatise on wine-making is essentially encyclopedic in character, and as such calls for only a brief notice. The author is evidently familiar with his subject, and in the limited space at his disposal has been very successful in reviewing both the scientific and economic position of the French wine industry. There is nothing novel in the scientific questions discussed in this book, but some of the economic questions brought forward are not generally recognised in this country. For instance, here we have been inclined to regard wine growing in France as only in process of recovery from the devastation wrought by phylloxera, and it comes as a surprise to be told by the author that the wine-growers of his country are at present suffering from the effects of over-production.

This little book will be useful to anyone who desires to make a rapid survey of the present position of the French wine industry. A. J. B.

A Commercial Geography of Foreign Nations. By F. C. Boon, B.A. Pp. viii + 174. (London: Methuen & Co). Price 2*s*.

THIS book will not assist to make commercial geography a scientific study. Like the geographical books of old time, the volume consists largely of disconnected details which no pupil ought to be asked to remember, and which produce weariness of the flesh in the unfortunate reader. If commercial geography means what Mr. Boon makes it, then it is the duty of all who are anxious for the introduction of reasonable methods of instruction in schools to condemn it at every opportunity. Here are a few examples of unqualified or loose statements which occur in the early pages of the book. "The greatest heat for the greatest number of days is on the Equator" (p. 1). "As the Equator is neared [from the Tropics] two days have vertical sunshine at each point within the Tropics, approaching gradually to the autumn and vernal equinoxes at the Equator" (p. 1). "Added to the effects of the neighbouring land or water are the similar effects of the winds that blow over them" (p. 2). "The Gulf Stream washes the coast of Norway" (p. 11). But we do not object so much to statements of this kind as to the principle of cramming pupils with information which has to be accepted without inquiry and cannot be assimilated. The less we have of commercial geography of this kind the more likely are we to create an interest in the study of the subject.

Mining Calculations. By T. A. O'Donahue. Pp. viii + 211. (London: Crosby Lockwood and Son, 1901.) Price 3*s*. 6*d*.

THE primary object of this little book is to enable candidates for certificates as colliery managers to obtain with a minimum of trouble a sufficient knowledge of arithmetic and mensuration to pass their statutory examinations. If the student will steadily work out the numerous useful examples given by the author, his chances of success will certainly be increased. Some of the absurdly easy arithmetical questions, quoted from the official examination papers, do not tend to enhance one's respect for the statutory certificate; however, this is no fault of the author, who has simply written a book to supply a want created by the examiners appointed under the Coal Mines Regulation Act.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Inheritance of Mental Characters.

ALL biologists must be grateful to Prof. Karl Pearson for his extremely valuable and interesting paper reported in your issue of December 5, 1901 (p. 118). Inasmuch, however, as his conclusions are likely to be taken as the settled results of scientific research, it may be appropriate at this time to express certain doubts which naturally arise on reading the abstract. A man at the age of thirty, for example, possesses certain physical, intellectual and moral qualities. These must be due to more than one class of factors, and may possibly be due to three:—

(1) Heredity; characters derived from ancestors, including for present purposes the results of normal variation.

(2) Environment.

(3) Soul; supposing that the man is something more than an intelligent mechanism, and considering the possibility that his soul may have preexisted his advent here as an individual of *Homo sapiens*.

The third factor will be ridiculed by many, but if it has any reality it may eventually be capable of demonstration by just such methods as Prof. Pearson employs. The first and second factors are universally recognised.

Now it is apparent at once that the influence of the several factors is not the same on all the qualities of the man. Stature will depend almost wholly on the first set of factors, eye-colour wholly so. On the other hand, health will certainly depend largely on the second, so will shyness, intelligence, &c.

If, therefore, it is found that stature and eye-colour exhibit exactly (or almost exactly) the same degree of divergence from parental or fraternal standards as do health, shyness, &c., may it not be that this disproves just what it seems to prove, because A does not equal B, but equals $B+x$?

It may be said that the statistics given are based on pairs of brothers, whose environment must have been almost identical, and hence the second factor would not affect the divergence between them. But this appears a doubtful argument, because (1) the treatment of successive children is very commonly not the same, and the fact of being an elder child is itself influential; (2) germinal selection must be supposed to be going on from the earliest moment of existence, and very slight environmental factors may make great ultimate differences.

There is another consideration, that of the stability of the different qualities in the race. Characters which were highly variable would not appear to be inherited to the same degree as those which were very stable. This might also appear in cases of atavism, where the pendulum of variability took an exceptionally long swing, going back to ancestral features of which we possessed no record. Thus let the inheritance be expressed by A B C D E A B C D E A B, &c., instead of A B A B A B, &c. In the former case our data might only cover A B C D, in the latter A B A B. We should say that the individuals of the latter series came very "true," those of the former not at all, though the result in the long run might be about the same in either case. Lest it be said that the former series is wholly imaginary, I will cite the case of the domestic dog. The ordinary mongrel street-dogs in a single town would afford material for several genera and very numerous species, judging them by the physical standards we employ for wild animals. Yet the domestic dog, taken as a whole, has not changed very much in long periods. That is to say, the extraordinary variability presented is not progressive under existing conditions, and we return sooner or later to about the starting point. T. D. A. COCKERELL.

East Las Vegas, New Mexico, U.S.A., December 20, 1901.

I AM not unmindful of the possible influence of environment in increasing the correlation of brothers. I strongly suspect that home influences have a good deal to do with the rather exaggerated value for the fraternal correlation in the category of *conscientiousness*. But certain characters, *e.g.* the cephalic index after three years of age, the eye-colour between twenty and thirty

and the hair-colour from seven to fourteen are but little, in England at any rate, subject to environmental influence. The cephalic index remains almost constant throughout life. Now the mean value for the fraternal correlation for these three characters is 0·5161, and for stature, span, forearm and health, which might be supposed to be largely influenced by environment, it is 0·5179. It thus seemed to me that environment was not an important factor in modifying the correlation of the *physical* characters between brothers. In other words, *environment does not influence the constant uniformly in one direction*. This view was apparently appreciated by Prof. Cockerell when he wrote "the treatment of successive children is not the same." Any influence of environment, strange as it may seem, was thus found to be negligible. Turning to the intellectual characters, my own *a priori* conception was that I should for the first time be able to distinguish between nurture and heredity. I expected much higher correlations in the case of temperament and probity than in that of physique. I was therefore somewhat surprised when the values came out much the same as in the case of the physical characters, say an average of 0·5. Of course it is open to Prof. Cockerell to say that 0·3 of this only is due to heredity and 0·2 to environment, or whatever other division appears to him probable, but he will then have to explain why the sum of the two makes 0·5, and why the influence of heredity is less in the intellectual than it appears to be for the physical characters. There is the obvious direct scientific interpretation which seems to me the true one, environment does not act in one direction in *either* case, and the mental and physical characters are inherited precisely at the same rate. To those who have taken the trouble, as I have done, to examine carefully the mental characteristics of a family at intervals of a century apart, so that we are not troubled by the co-environment peculiar to brothers, it is needless, perhaps, to urge the very strong inheritance of mental qualities. If Prof. Cockerell attributes it to his third factor, "pre-existing soul," I should, indeed, be proud to have aided in the demonstration of its reality, although I fail entirely to see how it is to be done "by just such methods as Prof. Pearson employs." Meanwhile most people will, I think, prefer to stick to heredity.

Of the last paragraph of Prof. Cockerell's letter I understand not a word. Correlation is quite independent of variation, and although skull capacity is highly variable as compared with length of femur, I see no reason for supposing the former is therefore less strongly inherited than the latter.

I have not touched on the influence of "local races" on my data, because that appears to be a factor which has escaped Prof. Cockerell, and so I am not bound to state a doubt which I have well considered in order to reject it.

KARL PEARSON.

Magnetostriction of some Ferromagnetic Substances.

WE avail ourselves of your valuable Journal to give a short notice of some new results, obtained in our researches on magnetostriction, being a continuation of our investigation on the same subject, given in the "Rapports présentés au Congrès international de Physique," t. ii., by one of us.

It was generally believed that ferromagnetic bodies show change of length by magnetisation, but not of volume. Minute as the effect generally is, it is now placed beyond dispute that iron, nickel, cobalt and especially steel differ also in bulk in the magnetised state from that in the unmagnetised. In the course of our researches on the magnetostriction of different ferromagnetic bodies in the form of ovoids we came across a substance which shows a remarkably large increase of volume.

Examining the magnetostriction of reversible nickel-steels of different composition, which were kindly placed at our disposal by Dr. Guillaume and M. Dumas, we find that alloys containing 46 per cent., 36 per cent. and 29 per cent. of nickel all show increase of length several times greater than that observed in ordinary iron. But far more striking is the change of volume; of the three above-mentioned alloys, the effect increases as the percentage of nickel becomes less; with 29 per cent. alloy we observed a motion of 5 mm. of the liquid in the capillary tube (diam. 0·4 mm.) attached to the volumenometer containing the specimen (volume $v = 10$ c.cm.) under examination. Thus the greatest change of volume by magnetisation amounts to $\delta v/v = 51{\cdot}1 \times 10^{-6}$ in $H = 1690$ C.G.S. With ordinary iron, the same change $\delta v/v = 1{\cdot}2 \times 10^{-6}$ in the same field, being only about 1/40th of that observed in nickel-steel. The magnetisation of 25 per cent. nickel alloy is so feeble that it is impossible for it to be magnetometrically measured, and the change of length is inappreciably small, but the volume change is measurable and amounts to $0{\cdot}2 \times 10^{-6}$ in $H = 1790$. It is thus quite probable that there is an alloy containing somewhat more or less than 29 per cent. of nickel that indicates largest increase of volume by magnetisation.

We at first thought it would be possible to trace some connection between the thermal expansion and the change of length by magnetisation. No such relation seems to exist; the 36 per cent. alloy, which is the least expansible by heat, indicates tolerably large elongation by magnetisation.

As regards the Wiedemann effect, nickel-steels behave very much like iron, showing the maximum amount of torsion in moderate fields.

As is well known, the behaviour of cast cobalt, as regards the change of length by magnetisation, is opposite to that of iron, but the volume change in the same metal is much smaller. By annealing cobalt in a charcoal fire it assumes a pale ashy colour, and the magnetic character is greatly changed. The metal becomes less magnetisable, and shows constant decrease of length accompanied by increase of volume.

We have also found, by actual experiment, that the effect of stress on magnetisation and the magnetostriction in cobalt and in nickel-steel are reciprocally related to one another, as was already established for iron and nickel.

Results of International Magnetic Observations made during the Total Solar Eclipse of May 17–18, 1901.[1]

To test further the results obtained by the United States Coast and Geodetic Survey magnetic parties during the total solar eclipse of May 28, 1900, regarding a slight magnetic effect that may be attributable directly to some change produced in the electrification of the upper atmospheric strata by the abstraction of the sun's rays due to the interposition of the moon between the sun and the earth, an appeal was made for international cooperation in magnetic and allied observations during the recent total solar eclipse.

The repetition of the observations was doubly interesting owing to the fact that the present eclipse occurred in the opposite magnetic hemisphere to that of the year 1900, and hence the opportunity was afforded for ascertaining whether the magnetic effect was reversed in its general character to that of 1900, as is, for example, the case with the diurnal variation in passing from one magnetic hemisphere to the other. The conditions, however, for obtaining observations at a number of stations distributed along the belt of totality, as was done in 1900, and thus testing whether the magnetic effect again followed directly in the wake of the shadow cone, were not favourable owing to the present location of the belt of totality.

In response to the appeal, simultaneous magnetic observations were made on May 17 from 14 to 21 o'clock Greenwich mean astronomical time—an interval amply covering the time of the eclipse—at a number of stations encircling the entire globe, three of which were in the belt of totality. The prime purpose of making the observations so as to cover the entire globe was to furnish the possibility of separating a possible eclipse magnetic effect from a contemporaneous magnetic storm of the usual type. The eclipse effect, for instance, doubtless would be confined to a very small belt, whereas a customary magnetic storm, in conformity with the usual experience, would manifest itself at practically the same moment of time over a very large area and thus be felt at stations far from the totality belt.

At none of the outside stations has a disturbance of any appreciable size been thus far reported to me, the general consensus of opinion of observers at these stations being that "nothing unusual occurred."

At the three stations within the belt of totality the majority of opinion is that something unusual did occur during the time of the eclipse.

[1] Presented before the meeting of the Astronomical and Astrophysical Society at Washington, December 30, 1901.

Thus at Karang Sago, where was situated the Dutch eclipse party, Dr. W. van Bemmelen, assistant director of the Batavia Magnetic Observatory, observed the changes in the magnetic declination and in horizontal intensity, and he reports the occurrence of "an extremely interesting magnetic effect." He has courteously sent me an extract of his observations, made during several days before and on the day of the eclipse, and there certainly appears evidence of a magnetic effect in both elements different from that observed on the days prior to the eclipse.

At Sawah Loento, the site of the Massachusetts Institute of Technology party of Boston, the variations in magnetic declination were observed by Mr. G. L. Hosmer on May 17 and 18. Comparing the two days' results for the interval of the eclipse, there is indisputable proof that something different occurred on the day of the eclipse than on the day before. Namely, at this station, situated so close to the magnetic equator, the range of the diurnal variation of the magnetic declination is about one minute of arc. The magnetic effect during the time of the eclipse was of about the same amount, so that a steady *decrease* of east declination resulted during the time of day when, normally, there is a steady *increase*.

There was but one magnetic observatory directly within the belt, viz. the one at Mauritius, and this was situated not far from the place of beginning of the eclipse. No special magnetic observations were made at this place, however, but regular photographic curves giving the variations in the magnetic elements were obtained. The declination and the vertical intensity curves apparently do not show any disturbance that could easily be picked out and referred to the eclipse. Regarding the horizontal intensity curve—the more sensitive one—Mr. Claxton states "that the original curve shows slight tremors between 7.15 and 7.50, and occasionally between 8.5 and 9.0 a.m." I have plotted this intensity curve on a larger scale, and find that the curve shows no very marked disturbance that might be readily referred to the eclipse, with the exception of one producing an easily perceptible bulge in the curve amounting to about 3–4 units in the fifth decimal C.G.S. units and lasting about 30 minutes. Anyway the effect, if there be one, is very minute, and will not be so readily separated from the usual diurnal variation as in the case of the two previous stations. Whether this is due to the fact that owing to the vicinity of Mauritius to the beginning of the eclipse the minute eclipse magnetic storm did not have time to develop itself or was just in the embryonic state cannot be said.

The magnetic effect observed at Karang Sago and at Sawah Loento does not appear to have extended very far outside the belt of totality, it being scarcely appreciable at the Batavia magnetic observatory.

My grateful and appreciative acknowledgments are due to all who have participated in this interesting investigation—one, to my mind, of fundamental importance to the theory of the diurnal variation of the earth's magnetism as elaborated by Schuster and von Bezold. L. A. BAUER.

The Roots of the Equation $u = \tan u$.

IN many treatises on optics it is stated that the roots of the equation, $u = \tan u$, were calculated by Schwerd. Verdet ("Oeuvres," t. v. p. 266), says :—"These roots have been calculated by Schwerd, who arrived at the following values : $u_1/\pi = 1{\cdot}4303$, $u_2/\pi = 2{\cdot}4590$, . . . " up to u_7/π. Preston ("Light," p. 255, second edition) says :—"The values of u corresponding to the maximum values of the illumination have been given by Schwerd as follows :—" The values given are precisely the same as Verdet's. Rayleigh ("Encyc. Brit.," vol. xxiv. p. 430, art., Wave Theory) gives a method for calculating the roots of the equation, and remarks that they were obtained in another manner by Schwerd. (There is a misprint in Rayleigh's value for u_4). Other references might be added.

Will someone kindly indicate where Schwerd gives the results referred to?

In his "Beugungserscheinungen" he shows that the roots of the equation are approximately the values of $(2n+1)\pi/2$, obtained by giving integral values to n; and he remarks (in § 63, p. 28) that for values $n=1$, and $n=2$, the true values of u differ by $12^\circ{\cdot}5$ and $7^\circ{\cdot}5$ from $3\pi/2$ and $5\pi/2$, respectively. In table i., at the end of the book, he gives values of the expression for the intensity, $\sin^2 u/u^2$, for values of u increasing by 15°; and at the foot of the table he states that the first and second maxima are at $257^\circ{\cdot}5$ (*i.e.* $270^\circ - 12^\circ{\cdot}5$) and $442^\circ{\cdot}5$ (*i.e.* $450^\circ - 7^\circ{\cdot}5$). Further details I have not found.

It may be remarked that the roots of the equation under consideration were given long before Schwerd's time. In Euler's "Introductio in Analysin Infinitorum" (Lausanne 1748) the question is fully discussed. See t. ii., cap. xx., prob. ix.

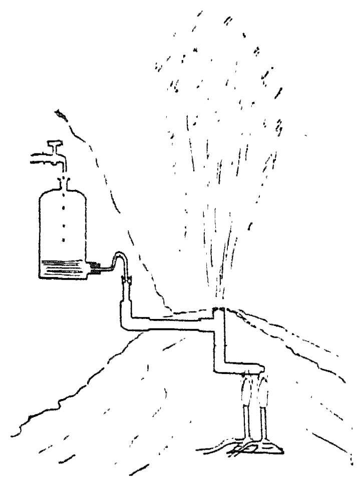
A Model Geyser.

IF the following working model, which was the outcome of a good many trials, is in any way original it may prove of interest, as it works automatically and with excellent effect as a geyser of regular period, suitable for a lecture table. The figure needs but little description. A small aspirator with a bent glass tube exit acts as an intermittent syphon. The water is discharged into a half-inch iron pipe, the long horizontal limb of which measures some 13 centimetres. The glass syphon tube slips through a rubber ring at the top of the pipe (gauge fitting), or a cork would doubtless answer the purpose. The lower closed end of the tube is heated by the equivalent of about four ordinary Bunsen burners, and should be placed as shown, as if placed



under the exit, steam is generated too fast and the water may be blown back into the aspirator. Water drips into the aspirator at such a rate that the syphon discharges about 300 c.c. of water once in every ten minutes. A jet of steam some six feet high and water some two feet high results, with many appropriate gurglings. The diameter of the exit is about 6 millimetres. Of course the apparatus is concealed; a large circular tin canister to which the iron pipe is screwed forms a good foundation and serves to keep the water off the burners. Furnace clinker, which is not wholly unsuitable, forms a readily obtainable material for completing the external features of the geyser.

Felsted, January. A. E. MUNBY.

Birds Capturing Butterflies in Flight.

WITH reference to Mr. Latter's letter in NATURE of November 16, 1899 (vol. lxi. p. 55), which has been brought to my notice, I would say that the supposition that birds do not attack butterflies in flight is not strictly correct.

The common King Crow (*Dicrurus ater*, I believe) invariably captures butterflies on the wing; I have seen these birds scores of times do this. Their usual prey seems to be a small deep yellow butterfly with black on the tip of the wings, but I have occasionally seen other butterflies so captured by them.

India, December 18, 1901. A. E. MCKAY.

THE FARMERS' YEARS.

I.

SOME years ago in the "Dawn of Astronomy" I showed how carefully the sun had been observed by the ancient Egyptians, not only when it rose or set at points most to the north or south, as at the solstices, but also when it rose exactly half-way between these points, that is, east and west at the equinoxes.

This fundamental division of the sun's apparent revolution and course which define our year into four

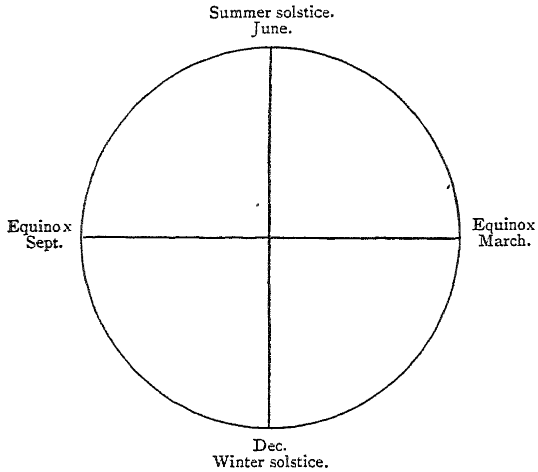


FIG. 1.

nearly equal parts may be indicated as in Fig. 1, the highest point reached by the sun in our northern hemisphere being represented at the top.

In order better to consider the problem as it was presented to the early astronomers who built observatories (temples) to mark these points, we may deal with the bearings of the points occupied by the sun on the horizon (either at rising or setting) at the times indicated.

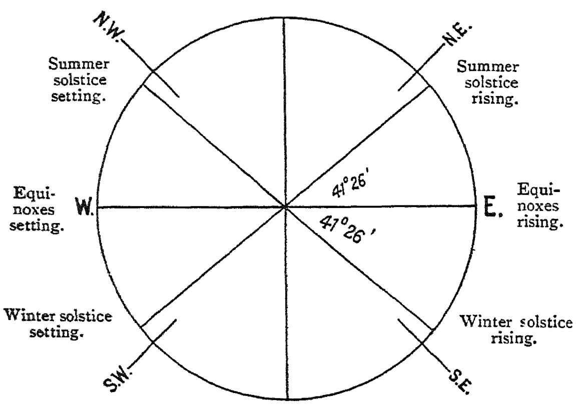

FIG. 2.—The various bearings of the sun risings and settings in a place with a N. latitude of 51°.

These points are conveniently defined by their "amplitude" or their distance in degrees from the E. or W. points of the horizon. In the diagram (Fig. 2) I represent the conditions of our chief British sun-temple, Stonehenge, in latitude 51° N. approximately.

Taking the astronomical facts regarding the solstices and equinoxes for the first year (1901) of the present century, we find:—

Sun enters	Aries,	Spring equinox,	March 21.
,, ,,	Gemini,	Summer solstice,	June 21.
,, ,,	Libra,	Autumn equinox,	September 23.
,, ,,	Sagittarius,	Winter solstice,	December 23.

These points, then, are approximately ninety-one days apart ($91 \times 4 = 364$).

In Fig. 2 I deal with the "amplitudes" at Stonehenge, that is, the angular distance along the horizon from the E. and W. points, at which the sunrise and sunset at the solstices are seen, the equinoxes being seen at the E. and W. points themselves. But as these amplitudes vary with the latitude and therefore depend upon the place of observation, a more general treatment is possible if we deal with the declination of the sun itself, that is, its angular distance from the equator.

The maximum declination depends upon the obliquity of the ecliptic, that is, the angle between the plane of the ecliptic and that of the equator at the time of observation. When the Stonehenge Sarsen Stones were erected this angle was $23° 54' 30''$. Its mean value for the present year is $23° 27' 7''$; it is decreasing very slowly.

It will be obvious from Fig. 2 that in temples built to observe the solstices or equinoxes, if they were open at both ends, looking in one direction we should see the sun rising at a solstice or equinox, and looking in the other we should see the sun setting at the opposite one. This, however, interfered with the ceremonial, which required that the light should illuminate a naos generally dark, so, usually, two temples were built back to back, with a common axis, as at Karnak.

In the beginning of astronomical observation it was more easy to align accurately a solstitial temple than an equinoctial one.

So much, then, for the chief points in what we may term the astronomical year, those at which the sun's declination is greatest and least. We see that they are approximately ninety-one days apart—say three months.

Now the priest-astronomers in these temples could only have won and kept the respect of the agricultural population with which alone they were surrounded in early times, and by whom they were supported, by being useful to them in some way or another. This could only have been in connection with what we may term generally the *farming* operations necessary at different times of the year, whether in the shape of preparing the ground or gathering the produce.

A very large part of mythology has sprung out of the temple cults, prayer, sacrifice and thanksgiving connected with these farming operations, in different lands and ages, but it is not my purpose to touch upon this side of the question now at length.

I wish to show, however, that by studying the orientation of ancient temples erected to watch the sunrise and sunset at times other than the solstices or equinoxes an immense amount of information may be gained if we endeavour to find the way in which the problem must have been attacked before the year was thoroughly established, and when it was still a question of grass- or corn-kings or gods who had to be propitiated.

In a solstitial temple the sun only makes its appearance once a year, when it reaches its greatest "north or south" declination: but in the temples dealing with lower declinations the sun appears twice, once on its journey from the summer to the winter solstice, and again on its return.

The first difficulty of the inquiry in the direction I have indicated arises from the fact that the products of different countries vary, and that identical farming operations have to be carried on at different times in these countries. We must, then, begin with some one country, and as the record is fullest for Greece I will begin with it.

The first thing we find is that the chief points in the farmer's year in Greece are about as far from the fixed points in the astronomical year as they well can be.

In the Greek information so admirably collated by M. Ruelle in the article on the calendar in Daremberg and Saglio's monumental "Dictionnaire des Antiquités Grecs et Romains," the earlier Gregorian dates on which the seasons were reckoned to commence in ancient Greece were as follows:—

Summer	May 6
φθινόπωρον	August 11
Winter	November 10
Spring	February 7

I may also add from the same source that in the calendars of the Latins the dates become:—

Summer	May 9
Autumn	August 8
Winter	November 9
Spring	February 7

Now we see at once that these dates are, roughly, half-way between the solstices and equinoxes.

This, then, at once brings us back to the orientation problem, which was to fix by means of a temple in the ordinary way dates nearer to these turning points in the local farmer's years than those fixed by the solstitial and equinoctial temples.

It must be borne in mind that it is not merely a question of stately piles such as Karnak and the Parthenon in populous centres, but of the humblest dolmen or stone circle in scattered agricultural communities, which were as certainly used for orientation purposes, that is, for recording the return of some season of the year important to the tiller of the soil, the advent of which season could be announced to outlying districts by fire signals at night.

I have already pointed out that any temple, dolmen or cromlech pointed to a sunrise or sunset at any dates between the solstices will receive the sunlight twice a year.

If the temple is pointed nearly solstitially the two dates at which the sun appears in it will be near the solstice; similarly, for a temple pointed nearly equinoctially the dates will be near the equinox; but if the ancients wished to divide the ninety-one days' interval between the solstice and equinox, a convenient method of doing this would be to observe the sun at the half-time interval, such that the same temple would serve on both occasions. This could be done by orienting the temple to the sun's place on the horizon when it had the declination 16° 20′ on its upward or downward journey.

What, then, are the non-equinoctial and non-solstitial days of the year when the sun has this declination?

They are, in the sun's journey from the vernal equinox to the summer solstice and back again,

May 6 and August 8 ... ... Sun's decn. N. 16° 20′.

Similarly, for the journey to the winter solstice and return we have

November 8 and February 4 ... Sun's decn. S. 16° 20′.

We get, then, a year symmetrical with the astronomical year, which can be indicated with it as in Fig. 3, a year roughly halving the intervals between the chief dates of the astronomical year.

With regard to the dates shown I have already pointed out that farming operations would not occur at the same time in different lands; that ploughing and seed time and harvest would vary with crops and latitudes; and I must now add that when we wish to determine the exact days of the month we have to struggle with all the difficulties introduced by the various systems adopted by different ancient nations to bring together the reckoning of months by the moon and of years by the sun.

In more recent times there is an additional difficulty owing to the incomplete reconstruction of the calendar by Julius Cæsar, who gave us the Julian year. Thus, while the spring equinox occurred on March 21 at the time of the Council of Nice, in 325 A.D., by the year 1751 the dating of the year on which it took place had slipped back to the 10th. Hence the Act 24 George II. c. 23, by which September 2, 1752, was followed by September 14 instead of by the 3rd, thus regaining the eleven days lost. This change from the so-called "old style" to the "new style" is responsible for a great deal of confusion.

Another cause of trouble was the forsaking by the Jews of the solar year, with which they commenced, in favour of the Babylonian lunar year, which has been continued for the purposes of worship by Christians, giving us "movable feasts" to such an extent that Easter Day, which once invariably marked the spring equinox, may vary from March 22 to April 25, and Whit Sunday from May 10 to June 13. It is at once obvious that no fixed operations of Nature can be indicated by such variable dates as these.

Hence in what follows I shall only deal with the months involved; these amply suffice for a general statement, but a discussion as to exact dates may come later.

With regard to the astronomical year it may be stated that each solstice and equinox has in turn in

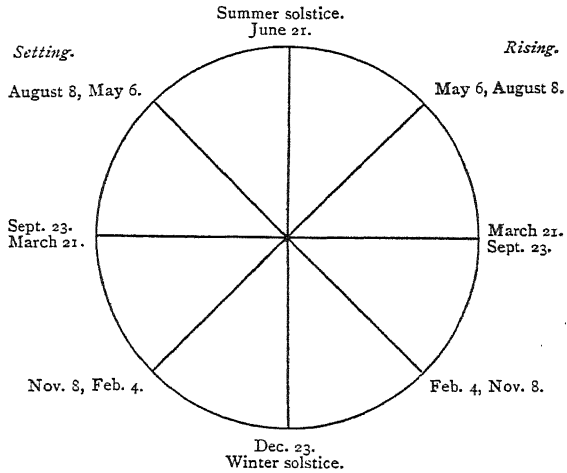

FIG. 3.

some country or another, and even in the same country, been taken as the beginning of the year.

We have, then, the following, so to speak, astronomical years:—

Solstitial Year.	June...........	December...............	June
	December ...	June	December
Equinoctial Year.	March	September	March
	September ...	March	September

Next, if we treat the intermediate points we have found in the same way, we have the following vegetation years:—

Flower Year.	May	November	May
	November ...	May	November
Harvest Year.	August	February	August
	February	August............	February

It will have been gathered from Fig. 3 that the temples or cromlechs erected to watch the first sunrise of the May–November–May year could also perform the same office for the August–February–August year; and in a

stone circle the priests, by looking along the axis in an opposite direction, could note the sunsets marking the completion of the half of the sun's yearly round in November and February.

Now to those who know anything of the important contributions of Grimm, Rhŷs, Fraser, and many others we might name, to our knowledge of the mythology, worships and customs in the Mediterranean basin and western Europe, an inspection of the first columns in the above tables will show that here we have a common meeting ground for temple orientation, vegetation and customs depending on it, religious festivals and mythology. From the Egyptian times at least to our own a generic sun god has been specifically commemorated in each of the named months. Generic customs with specific differences are as easily traced in the same months; while generic vegetation with specific representatives proper to the season of the year has been so carefully regarded that even December, though without May flowers or August harvests, not to be outdone, brings forward its offering in the shape of the berries of the mistletoe and holly.

With regard especially to the particular time chosen for sun-worship and the worship of the gods and solar heroes connected with the years to which I have referred, I may add that a cursory examination of Prof. Rhŷs' book containing the Hibbert lectures of 1886, in the light of these years, used as clues, suggests that in Ireland the sequence was May–November (Fomori and Fir Bolg), August–February (Lug and the Tuatha Dé Danann), and, lastly, June–December (Cûchulainn). Should this be confirmed we see that the farmers' years were the first to be established, and it is interesting to note that the agricultural rent year in many parts of Ireland still runs from May to November. It is well also to bear in mind, if it be established that the solstitial year did really arrive last, that the facts recorded by Mr. Fraser in his "Golden Bough" indicate that the custom of lighting fires on hills has been in historic times most prevalent at the summer solstice; evidently maps showing the geographical distribution of the May, June and August fires would be of great value.

Some customs of the May and August years are common to the solstitial and equinoctial years. Each was ushered in by fires on hills and the like; flowers in May and the fruits of the earth in August are associated with them; there are also special customs in the case of November. In western Europe, however, it does not seem that such traditions exist over such a large area as that over which the remnants of the solstitial practices have been traced.

I have pointed out that both the May and August years began when the sun had the same declination (16° N.) or thereabouts; once, on its ascent from March to the summer solstice in June, again in its decline from the solstice to September. Hence it may be more difficult in this case to disentangle and follow the mythology, but the two years stand out here and there.

With regard to August, Mr. Penrose's orientation data for the panathenæa fix the 19th day (Gregorian) for the festival in the Hecatompedon; similar celebrations were not peculiar to western Europe and Greece, as a comparison of dates of worship will show.

Hecatompedon	April 28	and	August 16
Older Erectheum	April 29	,,	August 13
Temple of Min, Thebes ...	May 1	,,	August 12
,, Ptah, Memphis ...	April 18	,,	August 24
,, ,, Annu ...	,,	,,	,,
,, Diana, Ephesus ...	April 29	,,	August 13

In the above table I have given both the dates on which the sunlight (at rising or setting) entered the temple, but we do not know for certain, except in the case of the Hecatompedon, on which of the two days the temples were used; it is likely they were all used on both days, and that the variation from the dates proper to the sun's declination of 16° indicates that they were very accurately oriented to fit the local vegetation conditions in the most important and extensive temple fields in the world.

This is the more probable because the Jews also after they had left Egypt established their feast of Pentecost fifty days after Easter = May 10,[1] on which day loaves made of newly harvested corn formed the chief offering.

With regard to the equinoctial year, the most complete account of the temple arrangements is to be found in Josephus touching that at Jerusalem. The temple had to be so erected that at the spring equinox the sunrise light should fall on, and be reflected to the worshippers by, the sardonyx stones on the high priest's garment. At this festival the first barley was laid upon the altar.

But this worship was in full swing in Egypt for thousands of years before we hear of it in connection with the Jews. It has left its temples at Ephesus, Athens and other places, and with the opening of this year as well as the solstitial one the custom of lighting fires is associated, not only on hills, but also in churches.

Here the sequence of cult cannot be mistaken. We begin with Isis and the young sun-god, Horus, at the pyramids and we end with "Lady day," a British legal date; while St. Peter's at Rome is as truly oriented to the equinox as the pyramids themselves, so that we have a distinct change of cult with no change of orientation.

If such considerations as these help us to connect Egyptian with Celtic worships we may hope that they will be no less useful when we go further afield. I gather from a study of Mr. Maudslay's admirable plans of Palenque and Chichén-Itzá that the solstitial and farmers' years' worships were provided for there. How did these worships and associated temples with naos and sphinxes get from Egypt to Yucatan? The more we know of ancient travel the more we are convinced that it was coastwise, that is, from one point of visible land to the next. Are the cults as old as differences in the coast-lines which would most easily explain their wide distribution?

NORMAN LOCKYER.

(*To be continued.*)

HABITS OF INSECTS.[2]

SEVEN volumes of M. Fabre's observations on insects have been published between 1879 and 1890, under the title of "Souvenirs Entomologiques," containing the results of long and patient investigations into the habits of insects of the south of France; and we are glad to see the first volume translated into English in its entirety. It is much better to begin at the beginning, rather than to issue merely a selection from the seven volumes, which was what we had expected to find when we opened the book. The English edition is tastefully got up, and the illustrations are attractive. We may say that there are none in the French except a few text-illustrations in some of the later volumes of the series. The English title, "Insect Life," is, however, somewhat objectionable, as there are already other English and American books bearing the same title.

The first volume, now to be noticed, includes twenty-two chapters, relating to the habits of the Sacred Beetle,

[1] Compare this with the fifty maidens who ran away from the Ultonian court (Rhŷs, "Hibbert Lectures," p. 434).

[2] "Insect Life: Souvenirs of a Naturalist." By J. H. Fabre, Docteur ès Sciences. Translated from the French by the author of "Mademoiselle Mori." With a preface by David Sharp, M.A., F.R.S., and edited by F. Merrifield. With illustrations by M. Prendergast Parker. Pp. xii+320. (London: Macmillan and Co., Ltd., 1901.) Price 6s.

various fossorial Hymenoptera of the genera Cerceris, Sphex, Ammophila and Bembex, and the Mason Bees of the genus Chalicodoma; and the volume is varied by autobiographical reminiscences, and an account of an ascent of Mont Ventoux. It is interesting to learn that M. Fabre's enthusiasm for entomological investigation was excited by his accidentally meeting with a pamphlet of Léon Dufour's on the habits of Cerceris as long ago as 1843. These observations, as the present volume shows, M. Fabre continued and completed with great success.

As regards the Sacred Beetle, M. Fabre considers that he has quite disproved the old idea that the balls of dung rolled by the beetle ever contain eggs; they are simply stores of food, and the real nest prepared for the egg is constructed underground later in the year.

M. Fabre's observations on the limitations of instinct in Hymenoptera are most curious and interesting, but are too long to be discussed here in detail; for these the book itself must be consulted. Suffice it to say, however, that they throw no light on the real nature of instinct, which remains more mysterious than ever; but only illustrate its manner of working.

The translation is very readable, sufficiently so to arrest the attention of a mere child who feels an interest in insects, notwithstanding that it sometimes deals with problems that no man living can yet answer. As an instance of the style of the book we will quote a portion of M. Fabre's account of the Praying Mantis:—

"A word more of the 'Praying Mantis,' the *Prégo Diéou*, as it is called in Provence, *i.e.* the Pray-to-God. And indeed its long pale green wings, like ample veils, its head upraised to heaven, its arms folded and crossed on its breast, give it a false resemblance to a nun in ecstatic devotion. All the same, it is a ferocious creature, bent on carnage. Although not especially favourite hunting-grounds, the workshops of various burrowing Hymenoptera are often visited by it. Posted on some bush near the burrows, it waits until chance brings some Sphex returning home within reach, thus achieving a double capture, catching together Sphex and prey. Its patience is long tried; the Sphex is suspicious and on her guard, but from time to time a rash one lets herself be caught. By a sudden rustle of half-spread wings, as by a convulsive movement, the Mantis terrifies the approaching Sphex, which hesitates for a moment, and then with the suddenness of a spring the toothed forearm folds back on an arm also toothed, and the insect is seized between the blades of the double saw, as though the jaws of a wolf-trap were closing on the beast as it takes the bait. Then, without unclosing the cruel machine, the Mantis gnaws little mouthfuls of its victim. Such are the ecstasies, the prayers, and the mystic meditations of the *Prégo Diéou*."

We hope the work will be completed by the translation of the remaining volumes of the series. At the same time, we regret to note that a few glaring technical errors in the translation have escaped notice. "Pattes" is usually translated "feet," but in almost every case "legs" would be the proper rendering. But what are we to think of such a passage as this, on p. 36, where the word "doigt" of the original, used for the five-jointed tarsus, is translated "claw"? "One claw to each foot is the rule, and this claw, at least in the case of the superior Coleoptera, especially the scavenger beetles, contains five joints." Again, in chapter ix., it is clear that the translator does not understand the real meaning of the terms "grillon," "criquet" and "acridien," and has sadly mixed them up, reversing "grasshoppers" and "crickets" in more than one passage. But when we object to "*Bupresticis micans* and *Buprestis flavomaculata*" beneath the plate opposite p. 46, we have exhausted our fault-finding, and warmly recommend the book to the attention of all who are interested in the habits of insects, and the many curious problems which they offer for our investigation.

FIG. 1.—The Sphex of Languedoc and its enemy, the Praying Mantis.

SOME SCIENTIFIC CENTRES.

III.—THE LABORATORY OF HENRI MOISSAN.

THE isolation of the element fluorine in 1886, the result of a long series of investigations carried out with an enthusiasm and manipulative skill and natural resourcefulness amounting to genius, has ensured Henri Moissan a high place in the history of modern chemistry.

His appointment in 1900 to fill the chair at the Sorbonne, rendered famous by its association with the names of the illustrious Dumas and Sainte-Claire Deville, sets a seal on a career of splendid activity.

Born in Paris in the year 1852, he commenced the systematic study of chemistry in the laboratory of the late M. Paul Dehérain at the Muséum d'Histoire naturelle. His first researches were in the direction of vegetable physiology, and in 1874 he made his *début* in a paper on the respiration of plants.

In the meantime, from 1872 until 1876, he was attending the course of Henri Sainte-Claire Deville. Under the influence of this teacher his interest was aroused in "la chimie minérale," and he carried out several investigations on the nature of the various oxides of iron, amalgams and the salts of chromium.

Obtaining his degree of "Docteur ès Sciences" in 1880, he received an appointment on the staff of the École de Pharmacie as "chef des travaux pratiques de I^{re} année." In spite of the laborious routine duties of his position, he found time to commence the examination of some of the compounds of fluorine "in the uncertain hope of at last being able to isolate the element." The next three years find him engaged on the problem which had baffled investigators from the time of Davy onwards. With patient and indefatigable zeal he continued, bearing up under repeated failure, and accumulating that valuable experience which enabled him to triumph over difficulties, and in 1886 to announce to the world that his efforts had been crowned with success. Fluorine was at length a chemical fact.

Before going on to describe the experiments by which Moissan led up to his final result, it will be interesting to glance at the attempts of previous workers and view them in the light of later discoveries; we shall then be in a better position to appreciate the value and the scope of his research.

Margaff and Scheele commenced the investigation of hydrofluoric acid in the latter half of the eighteenth century. Davy devoted considerable time to the isolation of the hypothetical element, and suffered a severe illness from breathing the fumes of the acid: he advised chemists to take special precautions against its action on the skin and lungs. Gay Lussac and Thénard fared in the same way. Knox, after repeating the work of Aimé, a French chemist, who attempted to replace fluorine by chlorine in silver fluoride, had to recruit his health in Italy for three years. Louyet, the next worker on the subject, paid the price of his enthusiasm with his life.

Frémy, in 1850, was the first to obtain anhydrous hydrofluoric acid, but the failure of his laborious researches seemed only to discourage further efforts in that direction; and, with the exception of some work by Gore in 1869, nothing more was attempted. Chemists accepted the inevitable, and were content to wait. Moissan, in approaching the subject in 1880, may be supposed to have recognised the dangers as well as the difficulties of his task.

The various experiments which culminated in the isolation of the element fall under four headings.

First of all Moissan made use of the fact that the high temperature of the electric spark is often capable of splitting up binary compounds into their constituent elements. He tried its effect on certain gaseous fluorides. Those of silicon and carbon were unaffected by it. The trifluoride of phosphorus was decomposed, probably into phosphorus and fluorine, but the latter element immediately combined with the excess of undecomposed trifluoride, and yielded the pentafluoride; thus

$$5PF_3 = 3PF_5 + 2P.$$

He then tried the pentafluoride, but found it far more stable than the corresponding chloride. It only split up under the influence of a very strong spark. Since the experiment had to be made in a glass vessel over mercury, it resulted only in the formation of the fluorides of mercury and silicon.

The trifluoride of arsenic was equally unsatisfactory. It was vaporised and sparked. There was reason to believe that decomposition occurred, but from the conditions of the experiment it was impossible to isolate the element.

Moissan now adopted a different plan of attack. Frémy had noticed that platinum fluoride, produced accidentally in one of his experiments, splits up under the influence of heat into platinum and fluorine. It was only logical to assume that, if the fluoride could be formed at a dull red heat, a sudden rise in temperature would result in the liberation of the element. The difficulty, however, was to obtain the platinum fluoride. On heating platinum in a current of the trifluoride of phosphorus, combination occurred, but not in the way desired, the chief product being a fluorophosphide of platinum.

Similar experiments with the pentafluoride of phosphorus indicated the hopelessness of expecting the desired result from work carried on at so high a temperature.

Moissan now had recourse to electrolysis. In the first instance he used trifluoride of arsenic contained in a platinum vessel, and found that if the material were quite pure and dry (B.P. 63°) it was decomposed into its elements. The fluorine, however, combined at once with the undecomposed trifluoride to form the pentacompound, while the arsenic sank to the bottom of the vessel, or remained suspended in the form of fine particles in the liquid.

It was found impossible to prepare the pentafluoride of arsenic by any chemical process, so that this substance, which would probably have solved the difficulty, had to be abandoned. The extremely poisonous nature of the arsenic compounds also rendered it desirable, if not indeed necessary, to find some more convenient electrolyte.

Moissan now returned to the early experiments of Davy, and took up the investigation of the effect of the electric current upon hydrofluoric acid. As both products of the electrolysis might be expected to be gaseous, a platinum U-tube had to be employed, so that the gases could be separated at the moment of their liberation. Further, to ensure the complete liquefaction of the acid, which boils at $+19^{\circ}\cdot5$ C., the apparatus was immersed in a bath of methyl chloride (B.P. -23° C.).

His first experiments confirmed the results which Davy had obtained, and which later on Faraday and Gore had explained, viz. that the anhydrous acid is a non-conductor. Moissan showed, in addition, that if the acid contains a small quantity of water, this latter is decomposed, until only the anhydrous acid remains in the U-tube, when the current ceases to pass. It was necessary, therefore, to add to the acid some substance which would enable it to conduct the electricity; such a substance is the acid potassium fluoride having the formula KF . HF. This can be obtained quite pure, and is very soluble in the anhydrous acid.

By this means it was found possible to decompose the hydrogen fluoride. The fluorine, however, immediately attacked the corks which had been covered with paraffin. Fluorspar stoppers were therefore substituted, and the experiment repeated. Hydrogen was evolved at the negative pole. In the other limb there collected an

apparently colourless gas with a penetrating disagreeable odour resembling that of hypochlorous acid. It was endowed with exceedingly active chemical properties. Hydrogen combined with it with explosive violence; most of the non-metals burnt in it, while the metals were less vigorously attacked. All organic substances were immediately decomposed.

Three hypotheses suggested themselves as to the nature of the gas. First, that it was a mixture of ozone and hydrofluoric acid. No such mixture, however, was found to exhibit the properties already described. Secondly, that it was a perfluoride of hydrogen; and thirdly, that it was the wished-for fluorine itself. This last point was settled by studying the action of water on the gas.

In the first case

$$\underset{4\text{ vols.}}{2HF_2} + H_2O = 4HF + \underset{1\text{ vol.}}{O}.$$

In the second

$$\underset{2\text{ vols.}}{F_2} + H_2O = 2HF + \underset{1\text{ vol.}}{O}.$$

By measuring the volume of oxygen liberated and titrating the quantity of hydrofluoric acid formed, Moissan was able to decide in favour of the third hypothesis: the gas must be fluorine.

The value of this work was at once recognised. Moissan was rewarded with the chair of "Toxicologie" at the "École de Pharmacie." "J'avais donc," he says, in a letter to the present writer, "très jeune un laboratoire, et un préparateur; quelques élèves vinrent se grouper autour de moi, et toute mon ambition fut satisfaite."

His faculties now had free play; he was able to work on a wider basis, and became one of the most prolific contributors to the *Comptes rendus*.

The isolation of fluorine was naturally followed by a systematic examination of its properties and derivatives. This work is still being carried on; recently, however, M. Moissan collected and published in one volume[1] the results he has obtained. They are all interesting, and some of great theoretical importance.

He found it more convenient and less costly to carry out the electrolysis of the anhydrous acid in a U-tube made of copper immersed in a mixture of acetone and solid carbonic acid, *i.e.*, at a temperature of -50° C. The electrodes as before were of platinum isolated from the apparatus by means of stoppers of fluorspar. The fluorine thus obtained was purified by passing it through a spiral cooled to -50° C., and then through a horizontal tube containing fragments of sodium fluoride; thus the hydrofluoric acid was removed. Perfectly dry fluorine which has been passed through a spiral immersed in liquid air, to solidify any traces of hydrofluoric acid remaining, has no action on dry glass even at the ordinary temperature.

It possesses a slightly greenish-yellow colour, paler than that of chlorine. It unites with greater or less violence with all the non-metals save oxygen, nitrogen and argon; the compounds being sometimes gaseous, and sometimes solid. The tri-, penta- and oxy-fluorides of phosphorus have been studied very completely; as also the fluoride of arsenic (AsF_3) and the tetrafluoride of carbon.

In the case of the metals the action is not so energetic, the solid fluoride formed on the surface of the metal preventing further combination.

The metals of the alkalis and alkaline earths take fire in the gas; lead combines slowly. Magnesium, aluminium, nickel and silver on slightly heating burn brightly on contact with the gas. Manganese heated in a current of fluorine yields a sesquifluoride, Mn_2F_6; this on further heating splits up into the difluoride, MnF_2, and liberates fluorine. Gold and platinum are unattacked in the cold, but combine at a dull red heat; the platinum fluoride has the formula PtF_4; at a higher temperature the gold and platinum compounds are decomposed into fluorine and the respective metal.

FIG. 1.—Prof. Moissan in his private laboratory.

Organic compounds rich in hydrogen are violently attacked by fluorine, and totally decomposed into hydrofluoric acid, and fluorides of carbon. Organic acids are attacked more slowly; amines and alkaloids are rapidly burnt up or decomposed into volatile products.

By indirect reactions involving the use of the fluorides of silver and zinc, Moissan and Meslans have been able to prepare and examine the properties of methyl, ethyl and isobutyl fluorides, fluoroform, acetyl fluoride, and a few other derivatives.

The latest determination gives the atomic weight of the element as 19·05.

A general survey of its chemical and physical properties confirms the surmises of Ampère and Davy: fluorine falls naturally into place at the head of the so-called "natural group" chlorine, bromine, and iodine.

[1] "Le Fluor et ses composés." Par Henri Moissan. (G. Steinheil, Paris, 1900.)

In 1896, Moissan and Dewar, working in collaboration, effected the liquefaction of fluorine by passing it through a tube cooled in liquid air which was allowed to boil freely. The B.P. of liquid fluorine is about -187°. The liquid does not solidify even at -210°. Its density is 1·14; it exhibits no absorption spectrum, and is not magnetic. It is soluble in all proportions in liquid air and oxygen. Liquid fluorine has no chemical action on liquid oxygen, solid mercury, or ice; but even at -210° it combines with hydrogen, and decomposes benzene with violence, and production of light and heat. It would be interesting to know the order in which the elements cease to react with fluorine as the temperature falls.

We must also refer to the hexafluoride of sulphur prepared by Moissan and Lebeau in April of 1900. It is obtained by the action of excess of fluorine on sulphur; it is one of the heaviest gases known, having a density of 5·03. Its composition, which is represented by the formula SF_6, completely establishes the hexatomic nature of the sulphur atom. It is of interest also on account of its inertness; it is unattacked by fused sodium or potassium. Resulting as it does from the union of two such active elements as sulphur and fluorine, which in combining seem thus to saturate one another completely, this compound may be regarded as additional evidence in favour of the theory of valency, though a chemical Ishmael might view it in a different light.

While engaged in studying the compounds of fluorine, Moissan's interest was aroused in the element boron; he obtained the amorphous variety in quantity, and caused it to unite with iodine, sulphur and phosphorus; he examined the action of alkali metals on boric acid, and, as we shall see later, in speaking of the electric furnace, prepared the carbide BC.

In 1891 the coveted honour of a seat in the Académie des Sciences was conferred upon him in recognition of his brilliant work. Cahours had died. To fill his place the names of Moissan, Grimaux, Ditte, Jungfleisch and Le Bel were submitted to the Comité. After a discussion lasting nearly two hours it was decided to nominate Moissan and Grimaux for election. The latter was defeated by eleven votes, and Moissan became the *confrère* of Berthelot, Friedel, Schützenberger and Troost.

The difficulty which was now hampering his work was one of temperature; he required a source of heat greater than that obtainable from the oxyhydrogen flame, and had recourse to the electric arc. In 1892 he devised the electric furnace, by means of which in its more perfect form a temperature of 3500° C. could be readily attained. The first result was the production of uranium from its oxide in fair quantities. Metals hitherto considered refractory yielded at once to the intense heat, and the electric furnace became in his hands the source of good specimens of chromium, tungsten, titanium, molybdenum, vanadium, zirconium, &c., all obtained from their oxides by reduction with charcoal.

In the following year, 1893, came the production of artificial diamonds, and Moissan's name became the prey of newspaper men and popular lecturers; chemistry began to appeal to the man in the street.

Moissan now took up the compounds of carbon with the metals, and obtained a whole series, comprising the carbides of sodium, potassium, calcium, strontium, barium, yttrium, lanthanum, thorium, aluminium, titanium, zirconium, chromium, uranium and manganese, and of the metalloids, boron and silicon. Quite recently he has added the carbides of neo- and praseo-dymium to the list. Proceeding in the same way with silicon and boron, he prepared the silicides of iron, chromium, tungsten, titanium, molybdenum, &c., and the borides of iron, nickel, cobalt, titanium, molybdenum, calcium, strontium and barium.

In 1898 he succeeded in his efforts to make calcium assume the crystalline form by dissolving it in sodium at a dull red heat, and dissolving away the sodium by absolute alcohol; from this crystalline variety he was able to pass to the hydride, nitride and phosphide of the element. By the electrolysis of fused calcium iodide he was the first to obtain the metal calcium in a state of purity.

When this series of experiments is completed, we shall be in a position to generalise from his results. Not the least interesting feature of the work is the bearing it will have on the Periodic classification; in this connection it should be of supreme importance.

But for the present we must be content with this necessarily brief *résumé* of the scientific work of Henri Moissan. As an experimenter he is unrivalled. "J'avais commencé à manipuler," he says, "de l'âge de 14 à 15 ans; et mes premières leçons de chimie, données par mon père, sont encore gravées dans ma mémoire." He is no theorist in the ordinary sense of the word. His work has been confined to the sphere of the purely practical; and for him a theory exists only that it may be submitted to the test of rigorous experiment, and for the sake of what it leads to. We can conceive of him working out a theory for the origin of diamonds; we find it difficult to conceive of him formulating a theory for the origin of man.

Unlike his distinguished compatriots, M. Berthelot and the late C. Friedel, who worked in both fields, organic and inorganic, Henri Moissan has remained true to the enthusiasm inspired by his first great teacher, Deville. "Je me suis appliqué à cultiver cette chimie minérale que l'on croyait épuisée, et je pense que mes travaux, ainsi que les belles recherches des savants anglais, ont pu démontrer que cette science réserve encore bien des dècouvertes à ceux qui voudront l'aimer et l'étudier avec tenacité." "To love it and pursue it with zeal" is the secret of Moissan's success, as it was of that of Davy and Faraday and Lavoisier.

In the midst of the gayest capital of Europe, but untouched by all the vicissitudes of its political life, he lives and works. "Ma vie a eu toute la simplicité de ma carrière de professeur, et mon existence s'est partagée, heureuse jusqu'ici, entre mon laboratoire et ma maison."

We can only wish him a continuance of this happiness, and in his new sphere an equal measure of success. The Science Faculty of the University of Paris is to be congratulated on the acquisition of so eloquent and so distinguished a teacher.

NOTES.

THE Geological Society of London will this year award its medals and funds as follows:—The Wollaston medal to M. Friedrich Schmidt of St. Petersburg, the Murchison medal to Mr. F. W. Harmer, and the Lyell medals to Mr. R. Lydekker and Prof. Anton Fritsch, of Prague; the Wollaston fund to Mr. L. J. Spencer, the Murchison fund to Mr. T. H. Holland, the Lyell fund to Dr. Wheelton Hind, and the Barlow-Jameson fund to Mr. W. M. Hutchings.

PROF. J. H. MARSHALL, who for three years past has been associated with Mr. Bosanquet in archæological researches at Athens, has been appointed Director-General of the Archæological Survey of India, for a period of five years in the first instance.

THE objects found during the recent excavations at Stonehenge will be on view in the library of the Anthropological Institute, Hanover Square, until January 21.

A MEDALLION bust of Sir George Airy is to be placed in the north-east wall of St. Alphage Parish Church, Greenwich, by his daughters. The bust has been copied from the one in the Royal Observatory, Greenwich.

WE regret to see the announcement that Mr. Clarence King, the eminent geologist, died at Phœnix, Arizona, on December 24, 1901. Mr. King was born in Newport, R.I., and graduated from the Sheffield Scientific School of Yale University in 1852. He was instrumental in the organisation of the U.S. Geological Survey, of which he was director from 1878 to 1881.

WE learn from the *Victorian Naturalist* that the monument erected over the grave, in the St. Kilda Cemetery, of the late Baron Sir F. von Mueller, K.C.M.G., for nearly forty-five years Government Botanist of Victoria, was unveiled on November 26, 1901, by His Excellency the Govenor-General, Lord Hopetoun, in the presence of a large gathering of public and scientific men and personal friends. The monument is in the form of a tall column of polished stone, surmounted by an urn, and resting on a broad pedestal. A medallion in copper of the profile of the late Baron is let into the stone above the inscription.

IT is reported from Paris that M. Ducretet is engaged in carrying out experiments on wireless telephony from which he has already obtained results which he considers are very promising. M. Ducretet's name has been associated with that of M. Popoff in connection with some very successful work in the development of wireless telegraphy. His present experiments do not seem to have gone beyond the laboratory stage, the distance over which speaking has been conducted being only thirty yards. The telephone currents pass through the ground, and it is said that M. Ducretet is about to investigate the conduction through different soils. We hope that he will meet with success, though we are inclined to doubt the practical utility of such a telephonic system, as it is difficult to see in what way, except as a scientific curiosity, it is likely to be superior to present methods.

IT is announced in *Science* that Dr. Ales Hrdlicka is about to start on his fourth expedition among the Indians of the south-western United States and northern Mexico. These expeditions are a part of the system of anthropological exploration and investigation known as the Hyde Expedition, and are carried on under the direction of Prof. F. W. Putnam for the American Museum of Natural History. The expenses of the present undertaking are generously provided for by Mr. F. E. Hyde, jun., of New York City. Dr. Hrdlicka is in charge of the somatological work of the Hyde Expedition, and his plan, now more than half fulfilled, is, in the main, to ascertain the physical characteristics of the extinct as well as the living peoples in that area which has once been occupied by the Cliff-Dwellers and Pueblos, and by the Toltec, Aztec and Chechemec peoples. It is hoped that on the present journey the somatological part of the research in the field will be completed.

DR. J. EVERETT DUTTON, of the Liverpool Malaria Expedition to the Gambia River, gives in a short report a few details of a peculiar case of fever in which he found a parasite resembling that of "tsetse fly disease" of cattle. The case was that of a European, who presented peculiar symptoms, namely: "Irregular attacks of fever lasting over a few days, the temperature not exceeding 101°. The attacks occurred irregularly for a period of some months; abnormal frequent pulse; an increased frequency of respiration, especially on exertion, were noticed. Besides general weakness there was a peculiar œdema of the eyelids and a puffiness about the face, as well as œdema of the legs. The spleen was enlarged, but there were no organic lesions of the heart or kidney, and the urine was normal. An examination of the blood revealed, in somewhat scanty numbers, a parasite, which actively travelled across the field of the microscope backwards or forwards, butting against the red corpuscles, and which was roughly determined to measure 20μ long and 3μ broad. The anterior end tapered off into a long cilium; the lateral membrane was distinct. A drop of blood under a cover glass contained some four to fifteen organisms." The organism is certainly a Trypanosome, but whether *Trypanosoma lewisi* or *T. brucei* or a new species is not yet certain. A single stained blood specimen accompanying the report shows an organism having a long anterior cilium and a rather blunt posterior end. The case was seen and the blood examined several times at the Royal Southern Hospital in September last, but no parasite of any sort could then be demonstrated in the blood. The fever on that occasion was also peculiar.

SOME observations on the seiches of the lake of Lucerne, by M. Ed. Sarasin, of Geneva, are described in the recently issued *Comptes rendus de la Société helvétique*, containing the proceedings for 1899. These observations, which were made at Lucerne, Fluelen and near Vitznau, showed that the period of the uninodal oscillation was 44 minutes, and of the binodal 24 minutes.

A CIVIL SERVICE examination in statistics was held for the first time in June, 1901, in connection with an open competition for the situation of assistant to the head of the statistical branch of the Board of Agriculture. It has been, therefore, considered of interest to reprint the papers both in this subject and in political economy in the *Journal* of the Royal Statistical Society for 1901.

THE preliminary report as to the population of England and Wales in 1901 is discussed by Mr. Thomas A. Welton, in the *Journal* of the Royal Statistical Society for December 31. In the ten years 1891–1901 the increase has been about 12·15 per cent. The large towns have more than held their own, and the new places noted in 1891 have maintained an average high rate of increase. This has been shared by many places which, though they had but from 1000 to 2000 inhabitants in 1801, were nevertheless classed as "progressive." On the other hand, all the towns treated as "unprogressive" in 1801–1891 have shown poor rates of increase, as have also many "progressive" towns which numbered from 2000 to 4000 inhabitants in 1801.

THE *Journal de Physique* for January contains a short abstract of a paper by P. van der Vlieth on an apparatus for demonstrating the linear conduction of heat, the original paper being in the *Journal* of the Russian Physico-Chemical Society. A bar of iron of section 5×5 cm. is heated by a jet of steam at one end and cooled at the other by a stream of water. Its lateral surface is covered by a thick coating of felt and cork, and a series of six thermometers is placed in holes made in the bar. After about half an hour the distribution of heat is stationary, and the temperature gradient as shown by the thermometers is almost exactly a straight line.

PROF. P. ZEEMAN, writing in the *Archives néerlandaises*, describes an experiment relating to the change of phase which occurs when a pencil of light-waves passes through a focus or focal line, a phenomenon to which Gouy has given the name of anomalous propagation. The experiments were made with a plano-convex lens of Iceland spar placed between two crossed nicols, and consisted in observing the rings produced by interference of the ordinary and extraordinary rays. When the centre of the system is black or white between the two foci, M. Gouy's theorem shows that it must be white or black respectively beyond the foci. Prof. Zeeman also gives an independent mathematical investigation of the phenomenon based on treating the focus as a doublet.

A HISTORICAL and critical essay of considerable length, on the definitions of the Bernouillan function, has been published by Prof. H. Renfer, of St. Gallen, in the *Mittheilungen der*

naturforschenden Gesellschaft in Bern for 1900, of which Messrs. Williams and Norgate have forwarded a copy. The essay consists in a detailed examination of the treatments of Raabe, Schlömilch, Schäfli and J. W. L. Glaisher, and the author gives tables as well as graphs of the functions according to the four corresponding alternative definitions. As a result of the examination, Prof. Renfer decides that L. Schäfli's definition is to be preferred on account of (1) its wider limits of convergency, (2) the greater simplicity of form of the formulæ, (3) this form being the most general, and (4) the theory assuming a more compact form on account of the assumed fundamental relation between Bernouillan numbers and functions and the applications of the principle of indeterminate coefficients.

THE "Antonio Alzate" Society, of Mexico, has published the proceedings and reports of the first national meteorological congress held in that country, and convened under its auspices on November 1, 2 and 3, 1900. The congress was attended by thirty-one members, chiefly directors of observatories and delegates of the various States. Many questions of general interest, mostly tending to ensure uniformity in the methods employed, were discussed. Some of the reports handed in contain valuable discussions of the rainfall and climate of various localities in Mexico. A paper was also read by a lady member, Señorita R. Sánchez Suárez, on the barometer and the prediction of weather.

ON comparing the principal meteorological results of the year 1901 at Greenwich Observatory with those of the last sixty years, the mean temperature (49°·6) is found to be −0°·5 below the average; there was nothing remarkable in the absolute extremes of temperature, the maximum being 87°·9, on July 19, and the minimum, 20°·4, on February 14, giving an absolute range of 67°·5. The rainfall, as in several previous years, was below the mean, the amount of deficiency being 3·28 inches; there was a slight excess in March and April, and a large excess, 1·74 inch, in December, while deficiencies exceeding an inch occurred in January and November. The amount of bright sunshine exceeded the mean of the last twenty years by 290 hours; the largest amount was recorded in May (237 hours), and the least in February (27 hours).

IN an illustrated article on the boats of the Samoans, in *Globus* (vol. lxxx. 1901, p. 167), Prof. Thilenius points out that the remarkable migrations of the Polynesians were accomplished by means of the *alia* or double canoe. Some of these canoes can accommodate more than a hundred persons, and the type extends from Hawaii to New Zealand and from Viti to the Marquesas.

SO little is known about the brains of primitive peoples that we welcome with especial pleasure the careful study of the brain of an Eskimo man by Dr. A. Hrdlicka in the *American Anthropologist* (1901, p. 454). As a whole this brain is heavier and larger than the average brain of white men of similar stature, and the cerebrum rather exceeds that of an average white male in the number, extent and depth of the sulci and in the complexity of the gyrations.

G. PAUL-BONCOUR gives, in the *Bulletins de la Société d'Anthropologie de Paris* (v. sér. t. ii. 1901), the first of a series of studies on the skeletal modifications consequent on infantile hemiplegia. This detailed study deals with the femur, and the author gives a careful comparison of the healthy femur with that of the paralytic side of a number of subjects. The last of his conclusions is the only one that will interest the general reader; he says: "From the anthropological point of view it has been possible pathologically to establish reasonable and clear transitions between human femurs and the femurs of anthropoids."

"NOTES on the Ancient Model of a Boat and Warrior Crew found at Roos in Holderness," by Mr. Thomas Sheppard, is the title of the fourth of the *Hull Museum Publications*. This little brochure, which is illustrated by four figures and two plates, is sold to the public for one penny. The curator is to be congratulated on producing such an interesting little essay on a remarkable model, probably of Scandinavian manufacture, of a wooden boat, the prow of which is carved to represent a snake's head with small quartz eyes. On the boat are four nude male figures, each of which was originally provided with a club and a large and a small round shield; their eyes also were pieces of quartz. The figures are from 14 to 16 inches in height.

ARCHÆOLOGISTS have long been accustomed to accept the statement that there is a hiatus between the Palæolithic and Neolithic stages of culture; but of late years more detailed research has indicated evidence of a transitional culture in the south of France and elsewhere. Quite recently A. Laville has investigated sections of certain hills in the valley of the Seine, and he claims (*Bulletins et Mémoirs de la Soc. d'Anthropologie de Paris*, v. sér. t. ii. 1901, p. 206) to have discovered two layers which he terms "Infra-Neolithic." These correspond, according to him, with the layers B and C of the famous cave of Mas d'Azil, so admirably worked out by E. Piette, and to which the attention of readers of NATURE has been called. There is a second paper (p. 285) by the same author, in which he figures a specimen from a basement zone which he claims to be an implement of the Chellian type, but in which M. Verneau cannot discover any evidence of human workmanship.

FIRE is regarded by the Hopi Indians of Arizona as a living being, its cultus consisting primarily of rites for germination, and, secondarily, for rain making. The lesser new-fire ceremony, which is described by Dr. J. Walter Fewkes in the *American Anthropologist* (n.s., vol. iii. p. 438), has these two purposes. The special gods worshipped are the germ-father and the germ-mother; the former is the fire god and is communicated with by means of prayer-sticks placed in his shrine, or prayer-fires kindled in the vicinity of the same. The germ-mother, called in this ceremony by the name of her animal personation (spider woman), is communicated with by invocations consisting of archaic monosyllables shouted by the chief. The personators of the ancient priests wear face-shields or masks; the latter have magic power, and their presence on the altar is a symbolic or mute suggestion of the elaborate ceremony of the ancients.

WE have received specimens of wall maps of Africa and South America, compiled and drawn by Prof. Guido Cora and published by Messrs. Paravia and Co. These maps, which are the first of a new series, are on a scale of 1 : 8,000,000, and show the physical features correctly and clearly. Ethnographic and political maps, on a scale of 1 : 25,000,000, are shown as insets; and profiles on a vertical scale of 1 : 200,000, along the equator in the case of Africa, and the parallel of 19° S. in the case of South America, form useful additions.

THE December number of *Petermann's Mittheilungen* contains several articles of more than average general interest. Prof. Gerland writes on Italian earthquakes and Baratta's seismic map of Italy, Prof. Wieser on the oldest map bearing the name "America," and Dr. Ernest Stromer on Lake Tanganyika. Dr. Vogelgesang concludes the first part of an account of journeys in northern and central China. Dr. Henkel contributes a note on the distance limit of visibility of land of a certain elevation from the sea, and adds a map of Greece showing the limits for a number of mountain summits.

THE marine submergence of the Gobi during the Secondary period becomes more and more doubtful, in proportion as we

learn more about this region. The Russian geologist, Bogdanovich, notwithstanding a most careful search, has found during his three years' journey no traces of this submergence. Stoliczka's fossils are apparently similar to those found by the Russian explorers further north, which have proved to be Devonian. Obrucheff's fossils from the eastern Gobi belong to freshwater lacustrine deposits. And now we learn from Prof. Tschernyscheff (*Verhandlungen* of the St. Petersburg Mineralogical Society, xxxviii. 2) that the fossils brought in by D. A. Klements from the Dzungarian Gobi, from a spot, Nyursu, situated to the east of Pyevtsoff's route from Kobdo to Guchen, belong to the Permo-Carboniferous strata, which are known in the Urals as the Artinsk horizon. They contain Bryozoa (Polypora and Fenestella), the polypes *Stenopora columnaris*, var. *Ramosa multigemmata*, and the molluscs *Productus purdoni*, *P. asperulus*, *P. mexicanus*, *Chonetes transitionis*, *Rhynchopora nikitini*, *Reticularia lineata*, *Martinia semiglobosa*, *Spirifer cameratus* and *Bairdia curta*. The character of this fauna is also similar to the fauna which was found by Loczy in the provinces of Se-chuen and Yunnan.

IN the *Notes* of the Leyden Museum (vol. iv. p. 191) Dr. F. A. Jentink describes a skin of the rare Bornean bay cat (*Felis badia*), which he believes to be the fourth known specimen. In the same issue Dr. O. Finsch continues his catalogue of the ornithological collection at Leyden.

IN the *Sitzungsberichte* of the Vienna Academy (1901, No. 25), Prof. R. von Wettstein draws attention to the important zoological and botanical collections obtained by the recent expedition to south Brazil. He directs attention to the marked changes caused in the vegetation of the country by plants introduced, either accidentally or on purpose, during the last century.

IN the January number of the *Entomologist*, Mr. F. B. Dodd describes a peculiar instrument by means of which the silk-producing moths of the Australian genus Antheræa cut their way out of their hard cocoons. The instrument "is a short hard black and curved thorn, situated in the thick joints at the base of the fore-wings, one on each side; in a rubbed specimen the thorn is easily discernible, but in a good one it is concealed amongst the dense scales. . . . It would be interesting to know whether anyone can state whence the liquid issues which the moth discharges to soften the cocoon where he cuts through; it must issue from near the thorn, for, as a rule, the scales left at the base of the wing and alongside the thorax are wet and matted when the moth emerges."

TO the issue of the *Journal* of the Straits Branch of the Royal Asiatic Society for July last Captain S. S. Flower contributes an interesting series of notes on the millipedes, centipedes, scorpions and allied creatures of the Malay Peninsula and Siam. The author sets an excellent example to other naturalists in the way he grappled with an unknown subject. "When I arrived in the Straits Settlements," he writes, "in March 1895, I knew practically nothing of these animals, how they were classified, how to distinguish between them, or which were poisonous and which harmless, and in no book or paper could I find the information I wanted, so I set to work to collect and examine specimens, and compare them with such literature as was available." The result of this energy and perseverance is the long and well-annotated list before us.

MR. G. ARCHDALL REID contributes to the current number of the *Monthly Review* an instructive and clearly written account of "the rationale of vaccination." After an explanation of the causes of zymotic diseases, it is explained that there are two kinds of immunity from them—the inborn and the acquired. The former prevents infection, the latter prevents reinfection, and both kinds have arisen in the human race through a process of natural selection. When, as in the case of measles, immunity can be acquired by the individual, natural selection has evolved a power of recovering from infection. Thus, Englishmen, who have long been afflicted by measles, are as certainly infected, but recover much more easily than Polynesians, to whom the disease has only lately been introduced. After passing in review the theories which have previously been held to explain acquired immunity, Mr. Reid shows that it is due to an habituation to the toxins of that disease. This result is brought about by the digestion in the blood of the toxins, so that there are present in the animal's blood toxins in all stages of attenuation, from those newly produced by the microbes, and extremely virulent, to those produced in the beginning of the disease and now in a state of great enfeeblement. Up that graduated scale the cells of the animal react till complete immunity is attained. The serum treatment artificially supplies digestive substances and, what is even more important, a scale of attenuated toxins. Applying these principles to the case of small-pox, the necessity for periodical vaccination is established. It is pointed out that, since small-pox is an air-borne disease, isolation, by itself, has no greater power of controlling small-pox than the historic old lady with a broom had of sweeping back the Atlantic. In the absence of vaccination isolation would be worse than useless.

A NEW edition (the third) of "Practical Radiography," by Messrs. A. W. Isenthal and H. Snowden Ward, has been published by Messrs. Dawbarn and Ward. Many additions have been made to the original volume, and the position and possibilities of radiography at the present time are fairly represented. The book is a useful guide to many aspects of work with Röntgen rays, and in it the authors judiciously combine practical hints with descriptions of theoretical interest.

THE German weekly scientific periodical *Die Natur* has just commenced a new half century in its existence, the first number having appeared on January 3, 1852. The journal was founded by the late Dr. Otto Ule and Dr. Karl Müller, and has maintained a high position among scientific periodicals from the commencement. The present editor is Herr H. Behrens. The cordial relationship which has existed between the French and German periodical representatives of Nature and ourselves is one instance among many of the cosmopolitan character of scientific interests. We congratulate *Die Natur* upon its jubilee and trust that its work and influence in the future will be even more extensive than in the past.

MR. C. E. BENHAM has prepared a series of seven stereoscopic diagrams, published by Messrs. Newton and Co., illustrating the polarisation of light. These diagrams show, in stereoscopic relief, the various directions of vibration in a light-wave, the passage of a ray through a doubly refracting crystal, the action of Nicol's prisms, and polarisation by reflection. The figures are drawn in white lines on a black ground, and they should be very useful for demonstration purposes. The only fault we have to find with them is that the right-hand and left-hand blocks in several cases are of unequal size, and present in the stereoscope the appearance of pieces of black paper which have been turned up at one side and slant towards the observer instead of looking like screens placed behind the diagrams. This is particularly confusing when there are two diagrams on the same slide, and the black patches appear tilted in opposite directions.

THE additions to the Zoological Society's Gardens during the past week include a Patas Monkey (*Cercopithecus patas*), a Ground Hornbill (*Bucorvus abyssinicus*) from Kontagora, Nigeria, presented by Captain E. H. Lewis; a Common For

(*Canis vulgaris*) from Savoy, presented by M. Leon Montaigne; a White-crested Tiger-Bittern (*Tigriosoma leucolophum*) from West Africa, presented by Mrs. F. M. Hand; nine Pheasant-tailed Jacanas (*Hydrophasianus chirurgus*) from India, presented by Mr. Frank Finn; a Horned Capuchin (*Cebus apella*) from South America, a Feline Douroucouli (*Nyctipithecus vociferans*) from South Brazil, four Crowned Partridges (*Rollulus cristatus*) from Malacca, deposited; a White-tailed Gnu (*Connochaetus gnu*, ♀), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

DIAMETER OF JUPITER.—In continuation of his series of determinations of planetary diameters with the 26-inch refractor at Washington, Prof. T. J. J. See gives the reduced measures of Jupiter in *Astronomische Nachrichten*, Bd. 157, No. 3757. The observations were made during daylight, using the colour screen over the eye-piece for eliminating the secondary fringes, &c. For the final evaluation of the diameter sixty-eight measures are employed, extending over the period 1901 September 6–October 1; from these he gives:—

$$\text{Equatorial diameter of Jupiter} = 37''{\cdot}646 \pm 0''{\cdot}014 = 141{,}950 \pm 53 \text{ km.}$$

Prof. See thinks this very closely approximates to the absolute value of the diameter, and by comparing it with the value obtained at night, when the planet is seen as a very brilliant object on a dark background, he obtains a measure of the irradiation. The night value is $38''{\cdot}40$, which gives for the irradiation:—

$$I = 0''{\cdot}755 \pm 0''{\cdot}040 = 2847 \pm 150 \text{ km.}$$

As these values are so different, the suggestion is made of the advisability of adopting two sets of planetary diameters, one representing the apparent size of the planet as seen at night, to be used in physical observations and ephemerides, work on satellites, &c., the other representing the true dimensions of the spheroid independent of its illumination by the sun, to be employed in the theory of the planet's figure, constitution, &c.

The resulting absolute dimensions of the Jovian spheroid referred to the distance 5·20 are:—

Equatorial diameter	= $37''{\cdot}646$	= 141,950 km.
Polar diameter ...	= 35·222	= 132,810 km.
Oblateness	= 1:15·53.	
Assumed mass ...	= 1:1047·35 (Newcomb).	
Density	= 1·35 (water = 1).	

"THE HEAVENS AT A GLANCE," 1902.—This handy little publication for the present year is issued in a slightly modified form. The author has repeatedly had inquiries respecting the inclusion of one or more star maps, and the present edition is furnished with two, one showing the northern stars, the other the southern objects visible from Great Britain. Another additional feature is the small map of the moon, showing the principal lunar formations.

All the more important phenomena are given for the year, and a series of summaries of the particulars relating to variable and coloured stars, nebulæ, &c.

VARIABLE STAR CATALOGUE.—In the *Astronomical Journal*, vol. xxii. No. 514, the committee appointed by the Council of the Astronomische Gesellschaft publish a further catalogue giving the elements of stars which have been certainly recognised as variable since the publication of Chandler's third catalogue (*Astronomical Journal*, vol. xvi., pp. 145–172). The present list gives the definitive designations for 191 variables, and also for the three Novæ in Perseus, Sagittarius and Aquila.

CATALOGUE OF 100 NEW DOUBLE STARS.—*Bulletin* No. 12 from the Lick Observatory comprises the fourth catalogue of new double stars having distances under 5″, discovered by W. J. Hussey with the 36-inch telescope at Mount Hamilton. (The first three catalogues appeared in the *Astronomical Journal*, Nos. 480, 485, 494.)

The search is being conducted in a systematic manner, and it is hoped that the work when more advanced will afford data for an investigation into the distribution of close double stars in various parts of the sky, and of their numbers with respect to magnitude.

THE TEACHING OF MATHEMATICS IN PUBLIC SCHOOLS.

THE following letter has been sent to the Committee appointed by the British Association to report upon the teaching of elementary mathematics.

GENTLEMEN,—At the invitation of one of your own body, we venture to address to you some remarks on the problems with which you are dealing, from the point of view of teachers in public schools.

As regards geometry, we are of opinion that the most practical direction for reform is towards a wide extension of accurate drawing and measuring in the geometry lesson. This work is found to be easy and to interest boys; while many teachers believe that it leads to a logical habit of mind more gently and naturally than does the sudden introduction of a rigid deductive system.

It is clear that room must be found for this work by some unloading elsewhere. It may be felt convenient to retain Euclid; but perhaps the amount to be memorised might be curtailed by omitting all propositions except such as may serve for landmarks. We can well dispense with many propositions in the first book. The second book, or whatever part of it we may think essential, should be postponed till it is needed for III, 35. The third book is easy and interesting; but Euclid proves several propositions whose truth is obvious to all but the most stupid and the most intellectual. These propositions should be passed over. The fourth book is a collection of pleasant problems for geometrical drawing; and, in many cases, the proofs are tedious and uninstructive. No one teaches Book V. A serious question to be settled is—how are we to introduce proportion? Euclid's treatment is perhaps perfect. But it is clear that a simple arithmetical or algebraical explanation covers everything but the case of incommensurables. Now this case of incommensurables, though in truth the general case, is tacitly passed over in every other field of elementary work. Much of the theory of similar figures is clear to intuition. The subject provides a multitude of easy exercises in arithmetic and geometrical drawing; we run the risk of making it difficult of access by guarding the approaches with this formidable theory of proportion. We wish to suggest that Euclid's theory of proportion is properly part of higher mathematics, and that it shall not in future form part of a course of elementary geometry. To sum up our position with regard to the teaching of geometry, we are of opinion—

(1) That the subject should be made arithmetical and practical by the constant use of instruments for drawing and measuring.

(2) That a substantial course of such experimental work should precede any attack upon Euclid's text.

(3) That a considerable number of Euclid's propositions should be omitted; and in particular

(4) That the second book ought to be treated slightly, and postponed till III, 35, is reached.

(5) That Euclid's treatment of proportion is unsuitable for elementary work.

Arithmetic might well be simplified by the abolition of a good many rules which are given in text-books. Elaborate exercises in vulgar fractions are dull and of doubtful utility; the same amount of time given to the use of decimals would be better spent. The contracted methods of multiplying and dividing with decimals are probably taught in most schools; when these rules are understood, there is little left to do but to apply them. Four-figure logarithms should be explained and used as soon as possible; a surprising amount of practice is needed before the pupil uses tables with confidence.

It is generally admitted that we have a duty to perform towards the metric system; this is best discharged by providing all boys with a centimetre scale and giving them exercise in verifying geometrical propositions by measurement. Perhaps we may look forward to a time when an elementary mathematical course will include at least a term's work of such easy experiments in weighing and measuring as are now carried on in many schools under the name of physics.

Probably it is right to teach square root as an arithmetical rule. It is unsatisfactory to deal with surds unless they can be evaluated, and the process of working out a square root to five places provides a telling introduction to a discourse on incommensurables; furthermore, it is very convenient to be able to assume a knowledge of square root in teaching graphs. The

same rule is needed in dealing with mean proportionals in geometry.

Cube root is harder and should be postponed until it can be studied as a particular case of Horner's method of solving equations approximately.

Passing to algebra, we find that a teacher's chief difficulty is the tendency of his pupils to use their symbols in a mechanical and unintelligent way. A boy may be able to solve equations with great readiness without having even a remote idea of the connection between the number he obtains and the equation he started from. And throughout his work he is inclined to regard algebra as a very arbitrary affair, involving the application of a number of fanciful rules to the letters of the alphabet.

If this diagnosis is accepted, we shall be led naturally to certain conclusions. It will follow that elementary work in algebra should be made to a great extent arithmetical. The pupil should be brought back continually to numerical illustrations of his work. The evaluations of complicated expressions in a, b and c may of course become wearisome; a better way of giving this very necessary practice is by the tracing of easy graphs. Such an exercise as plotting the graph $y = 2x - \frac{x^2}{4}$ provides a series of useful arithmetical examples, which have the advantage of being connected together in an interesting way. Subsequently, curve-tracing gives a valuable interpretation of the solutions of equations. Experience shows that this work is found to be easy and attractive.

With the desire of concentrating the attention of the pupil on the meaning rather than the form of his algebraical work, we shall be led to postpone certain branches of the subject to a somewhat later stage than is usual at present. Long division, the rule for H.C.F., literal equations and the like will be studied at a period when the meaning of algebra has been sufficiently inculcated by arithmetical work. Then, and not till then, will be the time to attend to questions of algebraic form.

But at no early stage can we afford to forget the danger of relapse into mechanical work. For this reason it is much to be wished that examining bodies would agree to lay less stress upon facility of manipulation in algebra. Such facility can generally be attained by practice, but probably at the price of diminished interest and injurious economy of thought. The educational value of the subject is sacrificed to the perfecting of an instrument which in most cases is not destined for use.

To come to particulars, we think that undue weight is often given to such subjects as algebraic fractions and factors. The only types of factors which crop up continually are those of $x^2 - a^2$, $x^2 \pm 2ax + a^2$, and, generally, the quadratic function of x with numerical coefficients.

In most elementary algebra books there is a chapter on theory of quadratic equations in which a good deal of attention is paid to symmetric functions of roots of quadratics. No further use is to be made of this until the analytical theory of conics is being studied. Might not the theory of quadratics be deferred until it can be dealt with in connection with that of equations of higher degree?

Indices may be treated very slightly. The interpretation of negative and fractional indices must of course precede any attempt to introduce logarithms; but when the extension of meaning is grasped, it is not necessary to spend much more time on the subject of indices; we may push on at once to the use of tables.

It will be seen that our recommendations under the head of algebra are corollaries of two or three simple guiding thoughts, the object in view being—to discourage mechanical work; the means suggested—to postpone the more abstract and formal topics and, broadly speaking, to arithmeticise the whole subject.

The omission of part of what is commonly taught will enable the pupil to study, concurrently with Euclid VI., a certain type of diluted trigonometry which is found to be within the power of every sensible boy. He will be told what is the meaning of sine, cosine, and tangent of an acute angle, and will be set to calculate these functions for a few angles by drawing and measurement. He will then be shown where to find the functions tabulated, and his subsequent work for that term will consist largely in the use of instruments, tables and common sense. A considerable choice of problems is available at once. He may solve right-angled triangles, work sums on "heights and distances," plot the graphs of functions of angles, and make some progress in the general solution of triangles by dividing the triangle into right-angled triangles. Only two trigonometrical identities should be introduced—

$$\sin^2\theta + \cos^2\theta = 1, \text{ and } \frac{\sin\theta}{\cos\theta} = \tan\theta.$$

In short, the work should be arithmetic, and not algebra.

Formal algebra cannot be postponed indefinitely; perhaps now will be the time to return to that neglected science. We might introduce here a revision course of algebra, bringing in literal equations, irrational equations, and simultaneous quadratics illustrated by graphs, partial fractions, and binomial theorem for positive integral index. Side by side with this it ought to be possible to do some easy work in mechanics. Graphical statics may be made very simple; if it is taken up at this stage, it might be well to begin with an experimental verification of the parallelogram of forces, though some teachers prefer to follow the historical order and start from machines and parallel forces. Dynamics is rather more abstract; a first course ought probably to be confined to the dynamics of rectilinear motion.

It is not necessary to discuss any later developments. The plan we have advocated will have the advantage of bringing the pupil at a comparatively early stage within view of the elements of new subjects. Even if this is effected at the sacrifice of some deftness in handing a, b and c, one may hope that the gain in interest will be a motive power of sufficient strength to carry the student over the drudgery at a later stage. Some drudgery is inevitable, if he is ultimately to make any use of mathematics. But it must be borne in mind that this will not be required of the great majority of boys at a public school.

We beg to remain, gentlemen,
Yours faithfully,

G. M. BELL, Winchester.
H. H. CHAMPION, Uppingham.
H. CRABTREE, Charterhouse.
F. W. DOBBS, Eton.
C. GODFREY, Winchester.

CONFERENCE OF SCIENCE TEACHERS.

ONE of the most important of the many educational conferences which it has become customary to hold during the Christmas vacation is that arranged under the auspices of the Technical Education Board of the London County Council. The custom of inviting teachers of science from all parts of the country to attend meetings in London, to discuss the best methods of imparting instruction in the branches of science taught in schools and colleges, was inaugurated four years ago, and each successive year has seen a substantial increase in the attendance. While in 1899 fewer than a hundred teachers, inspectors and others responded to the invitation of the Technical Education Board, there were present at the meetings held on Thursday and Friday last at the South-Western Polytechnic, Chelsea, upwards of four hundred persons, among whom were representatives of every stage of science teaching.

The vice-chairman of the London Technical Education Board, Mr. T. A. Organ, presided at the first meeting and, in a speech welcoming the teachers present, referred to the neglect of science teaching in this country in the past and contrasted this with the admirable efforts made in Germany since the opening of their first chemical laboratories in 1827. As indicating the amount of leeway we have as a nation to make up, he pointed to the fact that there are nearly 10,000 more or less well-trained chemists employed in German factories, and, as half of them have undergone a complete course of several years' training in the technical high schools, it is not surprising that Germany should be gradually securing markets in which originally British trade was supreme. It is unnecessary to repeat

here the examples which Mr. Organ cited, since they have been many times referred to in NATURE. The Technical Education Board could profitably expend, said the chairman, two millions on the improvement of the provision for research in the chemical and engineering sciences alone.

Hygiene as a School Subject.

Papers were read by Miss Alice Ravenhill, on the teaching of hygiene, and by Dr. Francis Warner, on mental school hygiene. The former paper discussed several points. Can our schools be made to contribute to the work of raising the standard of health in the country? If it is desirable to teach hygiene in schools, how will the curriculum be affected by the addition of this subject? In what grades of schools should hygiene find a place, and what are the best methods of teaching it? It was rightly pointed out that hygiene is really the application to the health of the individual of most other sciences, and that instruction in physics and chemistry may very well be given a useful bias by pointing out their applications in the particular problems with which hygiene is concerned. Miss Ravenhill compared the teaching of hygiene in this country with what she had seen in the American schools during her recent visit to the States, and indicated several customs which might very well be imitated by English teachers.

Dr. Warner explained how the study of mental hygiene could be made to assist the work of the teacher. Since all mental action is expressed in movement and its results, the teacher can, by noting carefully the expression, balance and action in movement and response, of the pupil, learn much of the modes of action in the brain centres.

Natural History Teaching.

At the second meeting the chair was taken by Prof. Tilden, F.R.S., who in the course of his remarks gave it as his opinion that every educated man should possess a broad general acquaintance with the facts of biological science, and that consequently all boys and girls should have an opportunity of studying natural history. The best time for such study is probably in the holidays, for in these days of crowded school time-tables and compulsory organised games the children have no leisure hours in term time. This holiday work should not be in the hands of the ordinary school staffs, who cannot dispense with the rest of vacation weeks, but be under the care of special holiday instructors.

Addresses were delivered by Mr. F. E. Beddard, F.R.S., on the teaching of natural history, and by Prof. W. B. Bottomley, on the value of natural history collections for teaching purposes. Both speakers gave a number of reasons why natural history should be taught in schools, urging that in educative influence it is second to no subject. Mr. Beddard maintained that the teaching should be in the hands of experts, who might very well be itinerant lecturers visiting each school once or twice a week. He showed by means of a brief comparison of the horse and the donkey how natural history teaching can be conducted on research lines and so form an excellent way of training the observation and reasoning powers. He also made it clear that there need not be much expense attending the introduction of natural history into school teaching. Prof. Bottomley distinguished between natural history collections and museums; while the former are capable of assisting the teacher very much, the ordinary museum is of little value. The natural surroundings of all animals exhibited should be imitated as closely as possible, and the objects should be typical of the neighbourhood in the first place, but be supplemented by others characteristic of the great divisions of the animal kingdom.

Schemes of Nature-Study.

The principal of the University of London, Prof. A. W. Rücker, F.R.S., presided at the third meeting. Mr. R. Hedger-Wallace described American systems of nature-study. He followed the classification of the methods in common use in the United States which was recently made by Prof. Hodge, of Clark University, and gave the distinguishing characteristics of each of the eleven divisions recognised by Prof. Hodge. Most of the American schemes of nature-study are marked by an undesirable pretentiousness which teachers in this country would do well to avoid. Perhaps the best of the American methods is that of Cornell University, drawn up by Prof. Bailey, and many of the schedules and instructions issued to teachers throughout the States by the authorities of Cornell University might be copied in this country with great advantage to the teaching of nature-study in our own rural schools. Mr. Hedger-Wallace particularly condemned the sentimentality developed by much of the teaching in American schools.

Mr. D. Houston gave an eminently practical account of the plan for teaching nature-study in schools which he has worked out for the Essex County Council. In this scheme it is rightly recognised that the success of any method depends ultimately upon the equipment and enthusiasm of the instructor. Consequently great stress is, in Essex, laid upon the preparation of teachers for their work. A three years' course has been inaugurated, and in the first two of these teachers are trained by lectures and laboratory work in the branches of science which underlie any serious work in nature-study; while in the third year the student prepares a detailed monograph upon a special plant, a course which is found to give an insight into the methods of research and to help the teachers to put the children into the right attitude towards the work. Mr. Houston exhibited an interesting series of exercises performed by teachers in training and by children in schools, which showed very conclusively that the work in Essex is being done on scientific lines.

Prof. Rücker summarised the addresses and indicated the lines the subsequent discussion might profitably take. He insisted that, in the education of children, science must be brought into close connection with art and literature. Science should teach how to observe and how to reason from the observations made, but for the due expression of what has in this way been learnt a course in drawing and literature is imperative. He also pointed out that while schemes of study which have been found to work well in some schools in certain circumstances are valuable to all teachers, such courses of study must not be adopted *en bloc* by teachers. Every instructor should be continually improving his scheme of study, modifying it to meet the peculiar needs of his own classes.

During the short discussion which followed, Dr. Gladstone, F.R.S., referred to the work under the London School Board which he helped to systematise.

Technical Education in Rural Districts.

In the absence of the Countess of Warwick, Prof. H. E. Armstrong, F.R.S., presided at the concluding meeting of the conference. Mr. Hennesey, the principal of Lady Warwick's School, Bigods Hall, Dunmow, described the equipment and curriculum of his school, which he explained was a school of science in which the courses of study for rural schools drawn up by the Board of Education were adopted. The school at Bigods is attended by both boys and girls, and no disadvantages have been found to result from the plan of co-education. Mr. Hennesey explained that a difficulty is experienced when the third year is reached, since it is found that only 50 per cent. of the third-year students intend to remain in the country to take up agricultural and horticultural pursuits. Instead of making the work of the third and fourth years purely technical a compromise is effected, so that those children who will work in urban centres may not suffer. Purely technical subjects are excluded, and great care is taken to make all subjects as educative as possible. It has not been found that the general education of the pupils suffers from the agricultural bias given to the teaching.

Prof. Meldola, F.R.S., passed in review the pioneer work in secondary and technical education in rural districts which has been accomplished in Essex. He concerned himself chiefly with the difficulties which have been overcome. He said that the sporadic teaching of insufficiently educated adults which is so common in many counties does little good. The best kind of technical education is that given by experts to classes of suitably trained youths. Rural technical education will not be satisfactory until an intimate connection between the elementary and secondary school is established. At present few children from the elementary school pass on for a further period of study to the secondary school provided, like the school at Bigods, with every facility for teaching the broad principles of agricultural and horticultural practice. A thorough system of scholarships by which the best children of the elementary school could pass on to the secondary school would have excellent results.

Prof. Armstrong, in bringing the conference to a close, insisted that the success of schemes of technical instruction is in no way proportionate to the costliness of the equipment. Simple appliances are best, and workshops are more productive of good

work than elaborately fitted laboratories. Desk work must be dethroned to a large extent and the pupils be given more time in the open air.

The exhibition of home-made apparatus was not so good as usual this year. Judging from the remarks of many teachers present at the conference, this exhibition has in previous years been regarded as one of the most helpful of the items on the programme of events, and Dr. Kimmins, to whose energy the success of the conferences is due, should develop this side of the annual meetings as largely as possible in future.

A. T. SIMMONS.

A NEW RANGE-FINDER.[1]

THE instrument designed by Prof. Forbes is intended only for use with rifle fire. It is not suitable for long-range artillery, or for the Navy. This infantry type is by far the most difficult to produce, because, in addition to accuracy, extreme portability is an essential feature. At the same time, the infantry are more in need of some addition to their present resources than any one else, and the urgent need of such an instrument has been proclaimed and re-echoed by all our officers who have returned from the war in South Africa.

All methods of optically measuring the distance of an inaccessible object depend on using a base of known length, which must be measured on the ground, or else be part of the instrument. In the latter case the instrument can usually be worked by one man, who can find the distance without changing his position. This class of instrument is sometimes spoken of as short-base range-finders. Numerous patents for such instruments have been applied for; but the difficulties in the way of ensuring accuracy are so great that only one type has ever been perfected and generally used. The Barr and Stroud range-finder has been adopted by the Navy with most satisfactory results, and this has proved the fact that a short base ($4\frac{1}{2}$ feet) is not inconsistent with accuracy. For the use of infantry, however, where extreme probability, and accuracy, and suitability for ill-defined objects, such as men, bushes, rocks, &c., are essentials, this is an unsuitable instrument.

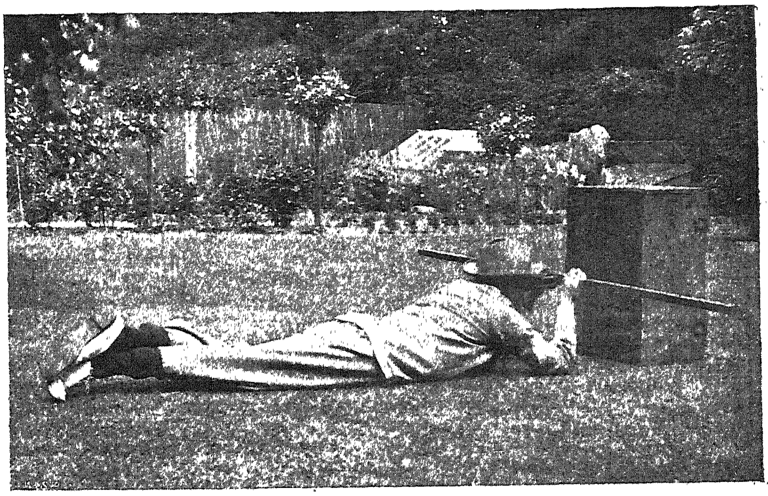

FIG. 1.—Range-Finder in use behind cover.

In the Barr and Stroud instrument the two images of a distant object are seen with one eye, hence the object appears to be double until the micrometer arrangement has been so moved as to make a coincidence of the two images, when the scale reading of the micrometer gives the distance directly. Now in naval work, for which this instrument is made, a ship, or its mast or funnel, is very sharp against the sky, and the coincidence can easily be made; but this method is almost valueless in the field. A bush, or a rock, or a man is an object so ill-defined, especially against certain backgrounds, that in attempting to make a coincidence you may move one picture in the telescope over the other for a considerable angle before you are sure that it is double. The difficulty has been got over by Messrs. Carl Zeiss and Prof. Forbes, who make use of stereoscopic vision in the new range-finder.

The instrument consists of a folding aluminium base, 6 feet in length, and a field glass. The base is a square tube hinged at its middle, and folds up to 3 feet 6 inches. Each half has at each end a doubly reflecting prism. The rays of light from a distant object strike the outer pair of these four prisms, are reflected at right angles along each tube, and are then reflected at the two middle prisms into the two telescopes of the binocular fixed to the base, in directions parallel to the original rays intercepted by the outer prisms. It is the measurement of the angle between these rays that tells the distance of the object looked at. This angle is measured by two vertical wires, one in each telescope, seen by the two eyes. One of the wires is fixed, the other is moved by a micrometer-screw until the two wires appear as one, while the object is seen distinctly. This gives the distance accurately to 2 per cent. even at 3000 yards. But now stereoscopic vision comes in and gives far greater accuracy. The wire seems to stand out solid in space, and the slightest turn of the micrometer screw causes the wire to appear to be nearer or farther than the object looked at, and when the wire appears to be at exactly the same distance the micrometer reading gives the distance with an accuracy far greater than that attainable by observing the duplication of images on the retina.

This range-finder can be used in a variety of positions. The more steadily it is held the more accurate the result. A standing position is the least steady. When kneeling, using only half the base, the other half may be bent down at right angles, and so form a leg which serves as a rest on the ground. The most easy position is sitting with the elbows resting on the knees. Another steady position is lying flat on the ground facing the object (Fig. 1). In every one of these positions you can take advantage of cover. Since the eyes are virtually at the extremities of the base, the observer may stand, sit, kneel, or lie behind a tree, bush, rock, ant-hill, horse, comrade, or waggon, and will not only be more able to work without sensation of danger, but without drawing the fire of the enemy on his comrades.

Lord Kitchener having expressed a desire to see the range-finder tested in the field, Prof. Forbes has proceeded to South Africa with his instrument, and a thorough examination of its efficiency will be made under practical conditions.

[1] Abstract of a paper read before the Society of Arts on December 18, 1901, by Prof. George Forbes, F.R.S.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE Prince of Wales having consented to be nominated as Chancellor of the University of Wales, has been elected to that office in succession to His Majesty the King, who has assumed the title of Protector of the University.

THE executive committee of the Carnegie Trust met at Edinburgh on Monday. The secretary and treasurer submitted their reports for the period ended December 31, 1901, showing that fees have been paid by the Trust to 2441 students, amounting to the sum of 22,941*l*. 16*s*. 6*d*. It was arranged to hold the annual meeting of the trustees in London, at which the first report of the executive will be submitted.

AT a special meeting of the Governors of University College Dundee, on January 8, Sir W. O. Dalgleish intimated that he would provide a sum of 5000*l*. for the building of the new medical school, and an additional sum of 5000*l*. towards the extinction of the debt on the College. This latter sum will be payable only if within a certain reasonable time sufficient money is subscribed to make up the remaining sum, the balance of

the debt—7500*l.*—in order that the debt of the College may be extinguished altogether.

AT a special meeting of the Court of the Victoria University, the recent movements to establish separate Universities in Liverpool, Manchester and Leeds were discussed. As the University College, Liverpool; Owens College, Manchester; and the Yorkshire College are the three constituent colleges of the Victoria University, the establishment of the three proposed Universities would mean the disruption of the present federated University. The two alternatives which the Court had to consider were as follows:—"Having regard to the resolutions of the three constituent colleges of the University, the question for decision must be whether (*a*) the three colleges are to remain as constituent colleges of the University; or whether (*b*) there should be a separate University in Liverpool and a 'University in Manchester without liability to admit or to remain in association with any other college,' and also a 'University established having its seat in Leeds.'" The latter view was accepted, and a committee was appointed to consider the terms and conditions on which it should be carried into effect.

THE New York correspondent of the *Morning Leader* says that the gifts to education in the United States in 1901 amount to more than 15,000,000*l.* Of this sum 9,000,000*l.* was contributed by three individuals. Mrs. Leland Sanford gave the magnificent sum of 6,000,000*l.* to the western University which bears her husband's name. Mr. John D. Rockefeller made an endowment of 1,000,000*l.* for the law school in the University of Chicago, and Mr. Andrew Carnegie has given 2,000,000*l.* to found an institution for scientific research at Washington. Mrs. Leland Sanford's gift of 6,000,000*l.* was in real estate and bonds and stocks. In making her gift Mrs. Sanford was actuated by the example of many wealthy persons in making bequests before their death in order to avoid possible will contests which might tie up the property for years. Mr. Carnegie's gift to endow research provides the United States with a fund which, wisely administered, will greatly strengthen university work in America and give an impetus to investigation which will have a profound influence upon the progress of the country.

THAT there is a widespread desire to modify the traditional methods of teaching the subjects of the ordinary secondary school curriculum and to bring them more into harmony with the practical needs of present everyday life, is strikingly shown by the frequent discussions on the desirability of reform in the teaching of mathematics which have taken place in the last few months. One of the most recent of such discussions was that which followed an address by Mr. W. C. Fletcher, headmaster of Liverpool Institute, at the meeting of the Incorporated Association of Headmasters held in London last week. Mr. Fletcher moved the following resolution, which was eventually adopted: "That this Association desires to press upon the universities and other examining bodies the desirability of greater elasticity in their regulations as to mathematical teaching, and is of opinion that to insist upon adherence to the order of propositions in Euclid is mischievous." Mr. Fletcher said that six years' experience of teaching geometry has led him to believe that Euclid is a great hindrance to ninety-nine boys out of every hundred in training and knowledge. A great deal of damage is done by insistence, not only upon the particular method, but on the particular order, of Euclid. As the result of his experience he had re-written the first half of Euclid's first book, omitted the second book, and introduced two or three propositions about proportion, in this way forming an interesting, sound and coherent plan. The headmasters were so impressed with the value of Mr. Fletcher's remarks that they decided to have his speech printed and circulated among teachers.

THE position of the University of Birmingham was described by the Vice-Chancellor, Mr. Chamberlain, at the second annual Court of Governors held on January 8. On the occasion of the former annual meeting the fund raised for the purpose of the University amounted to 330,000*l.*; it has now reached 420,000*l.* The Birmingham City Council has made a grant equal to a halfpenny in the pound on the borough rate, and this will provide about 5500*l.* per annum towards the ordinary maintenance of the University. The Staffordshire County Council has similarly identified itself with the aims of the University by making a grant of 500*l.* a year for five years in aid of the School of Mining and Metallurgy. It is hoped that the example will be followed by the county councils of Worcestershire, Warwickshire and Shropshire, and that the annual contributions from all these sources will amount to at least 7000*l.* per annum. With the practical assurance of this income, a sum of 300,000*l.* is available for the new buildings of the University. It is estimated that the buildings contemplated cannot be erected and equipped for a less sum than a million sterling. Out of the ten departmental blocks of the University, three are to be commenced, in the first instance, to accommodate the schools of mining and metallurgy, and of civil, mechanical and electrical engineering. A University Hall will also be erected. While the University buildings are being erected, the Mason College must be extended in some way and its equipment increased, in order to accommodate the additional students who have entered since the University was founded. For this purpose 10,000*l.* will be required, and Mr. Chamberlain announced that 6000*l.* had already been subscribed.

SCIENTIFIC SERIALS.

Annals of Mathematics (July and October, 1901).—Concerning Du Bois Reymond's two relative integrability theorems. The two theorems considered by E. H. Moore are, (1) a continuous function of (properly) integrable functions is integrable; (2) an integrable function of an integrable function is integrable. (1) was announced in 1880 and a proof published two years later (*Math. Ann.*, vols. xvi. and xx.). In connection with this proof (2) was announced. Dr. Moore in this note shows, by means of a simple example, that (2) is not true. Reference is made to a proof of (1) by Dini with an extension which is not applicable to the general case, but Dr. Moore extends Du Bois Reymond's general proof (1882).—P. Saurel, on a theorem of kinematics, gives an elementary demonstration of the well-known theorem that every displacement of a rigid body is equivalent to a rotation followed by a translation parallel to the axis of rotation.—The collineations of space which transform a non-degenerate quadric surface into itself, by Ruth G. Wood, discusses the ∞^6 collineations of space which transform the surface.—J. Westland contributes a note on multiply perfect numbers, with a view to determine all numbers of multiplicity 3 of the form $m = p_1{}^{a_1}p_2{}^{a_2}p_3$ where p_1, p_2, p_3 are three distinct primes and $p_1 < p_2 < p_3$.—The isoperimetrical problem on any surface, by J. K. Whittemore, gives a generalisation of the problem known to Pappus (see W. Thomson, "Popular Lectures and Addresses," vol. ii. p. 578). He solves Pappus's problem by the calculus of variations, and then solves, by an apparently novel method, the problem "Find a curve, $v = \phi(u)$, joining the two given points (u_0, v_0) and (u_1, v_1) having a given length L, and such that the area of the portion of the surface between the two curves, $v = f(u)$ and $v = \phi(u)$, shall be a maximum."—On a surface of the sixth order which is touched by the axes of all screws reciprocal to three given screws, by E. W. Hyde, has for its main object the determination and discussion of the envelope of a certain conicoid, which is touched by the axes of all screws of a certain system, so enabling one to grasp the nature of the system. The surface possesses other features of interest. The paper is illustrated with diagrams.—D. Sintsof, in a note sur l'évaluation d'une intégrale définie, discusses a previous note by M. Pell (evaluation of a definite integral, *Annals* (2), tome 1, No. 3).—The October number opens with a lengthy article (18 pp.) on the convergence of the continued fraction of Gauss and other continued fractions, by E. B. Van Vleck. Numerous references are given.—M. B. Porter supplies a short note on the differentiation of an infinite series term by term.—A note on geodesic circles, by J. K. Whittemore, discusses these circles in Bianchi's sense, viz. their definition is the locus of a point on a surface at a constant geodesic distance from a fixed point of the surface ("Vorlesungen über Differentialgeometrie," p. 160). Darboux ("Théorie Générale des Surfaces," vol. iii. p. 151) calls such a circle a curve of constant geodesic curvature. Mr. Whittemore gives three theorems—the first is, If, on a surface, there exists a family of concentric geodesic circles, such that the geodesic curvature of each curve of the family is constant, then the total curvature of the surface is constant along each curve of the family, and the surface is applicable to a surface of revolution, so that the geodesic circles fall on the circles of latitude of this surface.—Prof. Osgood gives a note on the functions defined by infinite series whose terms are analytic functions of a complex variable, with cor-

responding theorems for definite integrals. References to other memoirs abound.—Mr. C. L. Bouton gives an account of a game which he entitles "Nim" (a game with a complete mathematical theory). It is a game played at a number of American colleges and fairs and has been called "Fan-tan," though it does not correspond with the Chinese game of that name. He gives a description of the game (too curt, we think), and also discusses the theory of it.—Dr. G. A. Miller discusses the groups generated by two operators of order three whose product is also of order three, a short note, as is also the concluding one, on the invariants of a quadrangle under the largest subgroup, having a fixed point, of the general projective group in the plane, by W. A. Granville.

American Journal of Science, January.—An experimental investigation into the "skin" effect in electrical oscillators, by C. A. Chant. The skin effect was studied on sixteen cylindrical oscillators of various materials, including brass, iron, copper, gold, tin and silver, and of thicknesses varying from ·0000114 cm. upwards. The expected effect was not realised, as in the case of both the cylindrical and spherical oscillators the excessively thin gold shells were quite as efficient as the solid metal bodies.—The effect of hydrochloric acid upon the precipitation of cuprous sulphocyanide, by R. G. Van Name. In the presence of free hydrochloric acid the precipitation of copper sulphocyanide by a small excess of ammonium sulphocyanide is incomplete. The error can be reduced to a negligible amount by increasing the amount of the ammonium sulphocyanide.—The action of ammonium chloride upon certain silicates, by F. W. Clarke and G. Steiger. The minerals submitted to the action of the ammonium salt included stilbite, heulandite, chabazite, thomsonite, ilvaite, riebeckite, aegirite, serpentine, leuchtenbergite and phlogopite.—Studies of Eocene Mammalia in the Marsh collection, Peabody Museum, by J. L. Wortman. The present instalment deals with *Mesonyx obtusidens*.—A cosmic cycle, by F. L. Very.

SOCIETIES AND ACADEMIES.

MANCHESTER.

Literary and Philosophical Society, January 7.—Mr. Charles Bailey, president, in the chair.—The president announced that the Society was indebted to Dr. Edward Schunck, F.R.S., for a mural tablet, placed in the secretaries' room, bearing the following inscription: "This room was the laboratory of John Dalton; here his great discoveries were made, and here he conceived and worked out his atomic theory."—Mr. J. Cosmo Melvill exhibited many species of the genus Chrysanthemum, L., and described its affinities and subdivisions. He directed special attention to wild examples of *C. sinense* from China and *C. indicum* from both China and Japan, these two species being the origins of all the garden varieties, the former of the long-petalled kinds and the latter of the short-rayed and pom-pom forms.—Mr. R. S. Hutton described experiments which he had carried out at the Owens College on the fusion of quartz by means of the electric arc. He finds that, with suitable arrangement, there is no inconvenience caused by the reducing action of the arc, and that, owing to the much higher temperature, the fusion takes place with greater rapidity than with the oxy-hydrogen blowpipe. Methods were described for making tubes of quartz of any desired length in an electric arc furnace, and specimens of tubes were shown.—Dr. George Wilson read a paper on the failure of certain cast-steel dies used in the manufacture of drawn tubes. During the process of manufacturing tubes, the dies have occasionally fractured, to the danger of those using them, and an attempt has therefore been made to estimate some of the stresses to which such dies may be subjected. The results show that out of six fractured dies of which particulars were obtained, five had a factor of safety too small to cover flaws and dynamic effects. An example of the stress in a die is fully worked out, showing by curve the nature of the stresses and distortions.—Mr. C. E. Stromeyer exhibited some chemical gas washers which he had designed for dealing with relatively large volumes of gas. The largest apparatus was capable of dealing with about 50 litres per hour, and one of the smaller ones, designed to hold only six cubic centimetres of fluid and weighing only 40 grammes, was able to deal with 5 litres per hour.

PARIS.

Academy of Sciences, January 6.—M. Bouquet de la Grye in the chair.—On the focussing of a collimator or a telescope by means of the measurement of a parallax, by M. G. Lippmann. A point P at a finite distance from the collimator is viewed through an auxiliary telescope and brought on to the cross-wire of its eyepiece. The auxiliary telescope is now displaced parallel to itself through a known distance; if the image of P still remains on the cross-wire the collimator is correctly adjusted for parallel rays. If not, the collimator is adjusted until this condition is satisfied. The sensibility of the method depends on the magnifying power of the auxiliary telescope, and increases rapidly with the dimensions of the latter.—A method for verifying if a slider or a rule is rectilinear, by M. G. Lippmann.—The preparation and properties of potassium hydride, by M. Henri Moissan. The existence of a a hydride of potassium has been known for some time; in the present paper an account is given of the difficulties encountered in the preparation of this body in a pure state. Hydrogen acts very slowly at a temperature of 360° C. upon potassium, giving a white crystalline hydride of the formula KH. This is instantly decomposed by water, takes fire at the ordinary temperature in fluorine, chlorine and in dry oxygen. It possesses very energetic reducing properties, comparable to those of calcium hydride.—On a tumour of the tendon of Achilles, by M. Lannelongue. The changes in this tumour, which was not malignant, were followed by radiography. It was cured without treatment in two years, and as an operation was not necessary its exact nature remained doubtful.—The stability of a system, for any perturbations, affected by a movement of uniform rotation, by M. P. Duhem.—On the geographical position of In-Salah, an oasis of the Touatian archipelago in the Central Sahara, by M. G. B. M. Flamand. The latitude and longitude of this point, about which there has been some controversy, as well as of five other points, were redetermined by the Tidikelt expedition.—On certain systems of total differential linear equations, by M. Émile Cotton.—On the universal vibrations of matter, by M. A. Korn.—On the electrostatic field round an electric current, and on a theorem by Poynting, by M. W. de Nicolaïève. An experimental study the results of which are in exact accord with Poynting's theorem.—The general equations of electrodynamics in conductors and perfect dielectrics at rest, by M. E. Carvallo. An analytical expression and a dynamical interpretation for the two general laws of electrodynamics given in a previous paper is here deduced and the results compared with those of Maxwell.—A new method for the measurement and recording of high temperatures, by M. André Job. An application of the fact that the viscosity of a gas varies rapidly with the temperature. Oxygen gas is evolved at a constant rate from a voltameter and allowed to escape alternately through two capillary tubes, one of which is at a known temperature and the other at the high temperature to be measured. The pressure under which the gas escapes in each case is measured with a manometer, and by a direct comparison with a Le Chatelier couple it was found that the ratio of the excess of pressure in the two cases is a linear function of the temperature.—On the absolute value of the magnetic elements on January 1, 1902, by M. Th. Moureaux. The values given are for the observatory of Val-Joyeux.—The action of copper hydrate upon aqueous solutions of metallic salts, by M. A. Mailhe. The salts studied were the sulphates of cadmium, nickel, cobalt, zinc, manganese, mercury, aluminium and iron.—On the condensation of hydrocarbons of the acetylene series with esters. The synthesis of acetylenic acetones and β-ketonic ethers, by MM. Ch. Moureu and R. Delange. The reaction between the sodium derivatives of œnanthylacetylene and phenyl-acetylene with ten alkyl esters has been studied. The reaction takes place in two ways; in some cases the acyl derivative R—CO—C$\equiv$C—R′ is produced, which can be hydrolysed to the β-diketone R—CO—CH_2—CO—R′, in others the β-ketonic ester is obtained directly.—The utilisation of hexoses by the organism, by MM. Charrin and Brocard. From the point of view of utilisation by the organism, lævulose occupies the first place, galactose the second and glycose the third.—The presence of a parasite in the blood of epileptics, by M. M. Bra. Three microphotographs of the blood in epileptic patients under different conditions are given. The results appear to show that a microorganism is always present at the approach of and during the attack. This organism is a streptococcus, which would appear to have special morphological

and biological characteristics.—Contribution to the study of phosphorus as a plant food, by M. Th. Schlœsing, jun.—New observations on the evolution and origin of Peripatus, by M. E. L. Bouvier.—On the orientation of the Crinorhiza, by M. E. Topsent.—On the discovery of a nummulitic layer in a boring executed at St. Louis, Senegal, by M. G. Vasseur. From these observations the conclusion is drawn that towards the end of the lower Eocene period the sea, forming a vast gulf in the eastern portion of the Lybian desert and in the Arabian desert, and covering a part of Algeria, bent round to the north-west of the African continent and followed at a distance the line of the Atlantic coast, reaching on the south the basin of St. Louis.—Comparison of the Cretaceous basins of Eaux-Chaudes, Gèdre and Gavarnie, by M. A. Bresson.

ST. LOUIS.

Academy of Science, December 16, 1901.—A paper by Messrs. K. K. MacKenzie and B. F. Bush, entitled "The Lespedezas of Missouri," was presented by title.—Prof. F. L. Soldan delivered an address on the advance made in education during the nineteenth century, stating that the most characteristic feature of the century's progress lay in the epoch of expansion and organisation which it marked. The influence of Pestalozzi, Froebel, Horace Mann, William T. Harris and other distinguished educators was traced, the marked change in opinion concerning the commercial value of education brought out by the Centennial Exposition of 1876 was indicated, and the establishment of a true University grade in the United States with the opening of the Johns Hopkins University, the year following, was commented on.—Prof. F. E. Nipher stated that he had continued his experiments on the production of ether disturbances by explosions, and by the motion of masses of matter. He had apparently succeeded in eliminating the effects of the shock of the air-wave upon the magnet-needle. The needle is adjusted to a condition approaching maximum sensitiveness. There is no iron about the apparatus, except what is contained in the needle and in the compensating magnets. The latter are clamped in place so that the structure on which they are mounted may be pounded by a mallet without disturbing the needle. Rowland effects due to convection of electrified particles have also been eliminated. There remains a marked deflection of the needle, seeming to indicate that an ether distortion or wave originates in a sharp or violent explosion. This result is so amazing that it is announced with the statement that the whole subject is yet under the most searching examination. The coherer and the receiver of the telephone are to be used in two wholly different plans of experiment, in one of which the effects along the entire track of a leaden bullet are to be summed up in an alternating current. The results which seem to have been reached are in entire harmony with the well-known experiment of Michelson and Morley, who found that the ether within the building in which they worked was being carried along with the building and with the earth in its orbital motion.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 16.

LINNEAN SOCIETY, at 8.—On the Use of Linnean Specific Names: H. and J. Groves.—Exhibitions: Branches of Cherry affected by the Gnomonia Disease, with Remarks on its Effects and Climatic Causes: A. O. Walker.—Photographs and Specimens of Heads of Wild Sheep, to Illustrate a recent Suggestion as to the Use of Large Horns in Feral Species: J. E. Harting.

CHEMICAL SOCIETY, at 8.—Myricetin, Part II.: A. G. Perkin.—The Colouring Matters of Green Ebony: A. G. Perkin and S. H. C. Briggs.—An Investigation of the Radioactive Emanation produced by Thorium Compounds, I.: E. Rutherford and F. Soddy.

FRIDAY, JANUARY 17.

ROYAL INSTITUTION, at 9.—Interference of Sound: Lord Rayleigh.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Theory of Heat-Engines: Captain H. Riall Sankey.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Modern Machine Methods: H. F. L. Orcutt.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Dysentery in Asylums: Dr. Mott, F.R.S.—The Relation of the Dysentery of Asylums to that of South Africa: Dr. Washbourn, C.M.G.

MONDAY, JANUARY 20.

SOCIETY OF ARTS, at 8.—The Purification and Sterilisation of Water: Dr. Samuel Rideal.

TUESDAY, JANUARY 21.

ROYAL INSTITUTION, at 3.—The Cell: its Means of Offence and Defence: Prof. A. Macfadyen.

SOCIETY OF ARTS, at 8.—The Architect's Use of Enamelled Tiles: Halsey Ricardo.

ROYAL STATISTICAL SOCIETY, at 5.—Tonnage Statistics of the Decade 1891-1900: Sir John Glover.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—On some Rude Stone Monuments in Yorkshire: A. L. Lewis.—On a Group of Cairns with Megalithic Cists in the West of Scotland, and the Human Remains associated therewith: Dr. T. H. Bryce.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed*: American Workshop Methods in Steel Construction: H. B. Molesworth.

WEDNESDAY, JANUARY 22.

SOCIETY OF ARTS, at 8.—Scientific Observations at High Altitudes: Rev. J. M. Bacon.

GEOLOGICAL SOCIETY, at 8.—The Fossiliferous Silurian Beds and Associated Igneous Rocks of the Clogher Head District (Co. Kerry): Prof. S. H. Reynolds and C. I. Gardiner.—A Process for the Mineral Analysis of Rocks: Prof. W. J. Sollas, F.R.S.

THURSDAY, JANUARY 23.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: (1) Mathematical Contributions to the Theory of Evolution. XI. On the Influence of Natural Selection on the Variability and Correlation of Organs; (2) On the Correlation of Intellectual Ability with the Size and Shape of the Head. Preliminary Notice: Prof. K. Pearson, F.R.S.—A Short Description of the Culicidæ of India, with Descriptions of New Species of Anopheles: F. V. Theobald.—The Affinity of Tmesipteris with the Sphenophyllales: Prof. A. P. W. Thomas.—On the Excretory Organs of Amphioxus: E. S. Goodrich.

ROYAL INSTITUTION, at 3.—Recent Excavations at Delphi and in the Greek Islands: Dr. A. S. Murray.

SOCIETY OF ARTS, at 4.30.—Bengal: the Land and its People: F. H. Skrine.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Earth Currents derived from Distributing Systems: E. B. Wedmore.

FRIDAY, JANUARY 24.

ROYAL INSTITUTION, at 9.—The Discovery of the Future: H. G. Wells.

PHYSICAL SOCIETY, at 5.—The Factors of Heat. Part I.: James Swinburne.—Exhibition of some Twinned Crystals of Selenite: Eustace Large.

THURSDAY, JANUARY 23, 1902.

AN "ENERGETIC" VIEW OF EXISTENCE.

Vorlesungen über Naturphilosophie. By Wilhelm Ostwald. Pp. 457. (Veit and Co., 1902.)

LEIBNITZ once remarked that if we could imagine a human brain so magnified, without disturbing the relations of its parts, that we could move about in it as "in a mill," and could learn and understand all the mechanism of brain-atoms, we should see merely atoms in motion and should learn nothing of the thoughts which correspond with these motions. Du Bois-Reymond, in an address on the limits of our knowledge of nature, expresses a similar thought. Imagining that we could acquire knowledge of the processes occurring in the brain similar to that which we possess of the heavenly bodies, he says:—"As regards the actual mental processes, it is evident that even with such an astronomical knowledge of the organ of thought (Seeles-organ) they would elude our comprehension, just as they do now. In possession of such knowledge, we should still stand before them as before something completely intangible. An astronomical knowledge of the brain, the highest we can ever attain to, reveals to us nothing but matter in motion. By no conceivable arrangement or motion of material particles can a bridge be constructed which will lead us into the region of consciousness."

"I know of no more convincing proof of the philosophic value of the application of the doctrine of energy to our method of viewing the external world," continues Ostwald, after quoting the above paragraphs, "than that in the light of that doctrine, this ancient problem loses all its terror. For the difficulties are owing to the fact that Leibnitz and Du Bois-Reymond, following Descartes, make the assumption that the physical world is constituted entirely of matter in motion. In such a world there is no place for thought. We, who regard energy as the ultimate reality, perceive nothing of such impossibilities. We have seen that the effects of nerve-conduction can be referred without contradictory ideas to energetic precursors; and we have seen, too, that nerve-processes involving consciousness are continuously connected with those in which consciousness plays no part. I have tried my best to find anything absurd or unthinkable in the assumption that certain kinds of energy involve consciousness; but I have been unable to discover anything of the kind. We shall shortly be convinced, by an investigation of the most important phenomena of consciousness, that they are conditioned by transfer of energy; and it is no more difficult for me to think that one of the conditions of kinetic energy is motion than that the energy of the central nervous system must be accompanied by consciousness."

This quotation will give the reader a glimpse into the nature of the material considered by Prof. Ostwald in these lectures. In the present review I do not intend to offer critical remarks, but merely to present to the readers of NATURE a sketch of the system of philosophy which appears to Ostwald to be the outcome of the present position of our knowledge of physical phenomena. It would be ungracious, however, not to congratulate the author on the great interest which his book awakens, and on the exceedingly clear and lucid style in which he presents his ideas, in spite of the somewhat involved constructions which the nature of the language in which it is written necessitates. In his preface Prof. Ostwald, after asking the indulgence of his readers for many imperfections and omissions, expresses the hope that in the new journal, the *Annals of the Philosophy of Nature*, the false may be corrected, the imperfect completed, and the ideas of doubtful interpretation discussed.

The earlier portions of the work deal with a critique of the older philosophical methods which attempted to forecast and explain phenomena by thinking; Ostwald sets out with the aim of controlling and regulating thought by constantly keeping phenomena in view. Yet in order to convey our thoughts to others we must make use of words and conform to certain laws of thought. In fact, we employ our intellectual apparatus to fathom the depths and investigate the working of precisely that intellectual apparatus, a problem similar to the one solved by Baron Münchausen when he extricated himself from the bog into which he had sunk by pulling himself out by his own pigtail. The ordinary methods of science, however, are here applicable; we can examine various assumptions and accept that which appears best to fulfil its purpose. We can never attain certainty, or a knowledge of the absolute, in philosophy, nor can we, indeed, in any natural science; but we may arrive at conclusions which possess a high degree of probability. And in philosophy, as in science, we must be content with a gradual approach to truth, rejecting, in many cases, conceptions found to be at variance with experience. Philosophy, like science, is empirical; but as it progresses, the region of empiricism is narrowed, although it will never ultimately disappear.

The signification of certain terms is next expounded; experience, memory, comparison, conception, thing, object; and the nature of language and the danger of mistaking words for things. A plea is here entered for the adoption of an artificial language to be used only for science and business, avoiding ambiguities and attaching definite meanings to all its words. Some words of such a language have already been adopted, as, for example, meter and gram; our musical notation and our system of ciphering are universal, and to devise a universal language would be a distinct gain for the human race. A short account of the principal parts of speech and of the changes in meaning of words concludes the chapter. The part played by our senses in receiving impressions from without is next considered, and here the particular views adopted by the author first become prominent. In every affection of the senses a *transfer of energy* has occurred. It is in receiving impressions through the tactile sense that this is most obvious, and here, too, we are impressed by the existence of a *will*. The question whether the "external world" is not to be regarded as a mere phase of consciousness or as reality is solved thus: "We have not to ask, Is there an external world? but, What phenomena must we class under the name *external world?*" "Those which are independent of my will" is the answer; or again, "Those in which my organs of sense take part."

The formation of conceptions (Begriffe) requires five operations—receiving an impression, distinguishing it from others, connecting it with others, comparing it with others and, finally, reaching a conclusion. A

N

"thing" is an experience (erlebniss), generally external to ourselves, which we regard as separable or distinguishable from other experiences. But "things" are related to each other, and a collection of things forms a "manifold" or multiplicity (Mannigfaltigkeit). Ostwald illustrates the meaning of a "manifold" by the analogy of the contents of a boy's pocket; the articles have no other relation to each other than that they happen to be there. The laws of the manifolds of our experiences are represented by time and space. Time is characterised by continuity and by its being a "simple manifold," that is, from one point of time to another, there is only one path; and this implies that in time there are no points of intersection, there is only an earlier and a later, and these cannot be interchanged. Space, on the contrary, is a complex manifold, inasmuch as there is an infinite number of ways from any one point to any other, and it is "isotropic," or free from direction.

Manifolds (or collections of things in some way related) can be divided in an affinity of ways; their parts can be placed in order, and, in fact, all real manifolds must be ordered. A consideration of such order brings into operation our faculty of comparison. An instance is to be found in "ordinal" numbers, which form a manifold limited on one side, but unlimited on the other, uniform and ordered. The cardinal numbers, on the other hand, define merely the extent of a manifold, without reference to distinguishing between individuals. But ordinal numbers may be made unlimited in both directions by use of a negative sign.

The conception of magnitude next claims attention. The conceptions of identity and equality, and the impossibility of reaching certainty as regards the latter, the conditions of equality in time, the notion of continuity, and the law of interpolation lead up to the consideration of two kinds of magnitude—those which may be termed intensities or "strengths" (Stärken), and those for which the English word "capacity" or "quantity" appears the best translation (Grössen). While capacities may be subdivided into similar portions, these portions may be recombined in any proportion to reproduce a capacity of equal kind. On the other hand, intensities cannot be divided into similar portions, for each portion retains the characteristic property due to its position in the original intensity, even after subdivision. Capacities can be measured by use of cardinal numbers; thus, five litres of water remain five litres, whether they be contained in one or in a hundred vessels, whereas intensities require ordinal numbers to denote them, the first second of time is not the same as the tenth second, although it is equal to it; it is impossible to substitute the one for the other.

The restrictions of human thought by the conditions of time and space depend on the fact that while it is impossible to predict certainly what will be the consequence of any events, it is nevertheless possible to predicate what consequences are necessarily excluded. And no events in the external world are possible unless they happen in time and space. Given these conditions, however, there is an infinite possibility of events occurring. Kant's contention that space and time are "forms of thought" is considered by Ostwald to be due to our having inherited countless experiences in which these conditions of thought regarding external phenomena are essential.

And now, after 146 pages of preliminaries, we come to the features of this work which give it its definite character. Relying on the fact that in all our impressions from without the repetition of a certain individual impression at different times and seasons conveys to our minds a conviction of permanence, inasmuch as the mountains and the sea, our neighbours and ourselves, preserve identity, while exhibiting continual change, Aristotle summed up the conclusions formed by innumerable generations of his predecessors in attributing to each thing an unchangeable *substance*, its changes being ascribed to *accidental* variations. Ostwald now proceeds to inquire, What is the universal *substance?* And in what way are diverse things differentiated from each other? What is the most general *accidence* or condition of modifying substance? To this question the answer is, energy; it is the most general substance (the word being used in the signification of that which underlies all external things), for it is present in time and space, and it is also the most general accidence, for it can be differentiated in time and space. The substance of physicists and chemists is termed *matter*; but a definition of matter is avoided in most treatises on chemistry and physics. It is customary, however, to use the word "mass" in the sense of "quantity of matter." The seventy or eighty different kinds of matter are called elements. Extension, form and impenetrability are ascribed to matter, and it is regarded as indestructible. Among other properties imputed to it are inertia, weight, divisibility and porosity, but, as a rule, little emphasis is laid on the question as to which of these properties is essential and which adventitious. To the old conception of matter has been added in recent years that of ether; not, according to Ostwald, because its assumption leads to a satisfactory presentation of facts, but because people have been unable to devise any better assumption. Indestructibility, or permanence, too, has been ascribed to matter, but ponderable substances are not the only ones which possess permanence; that quality, for example, may likewise be predicated of momentum. Again, a quantity of electricity is permanent, regard being paid to positive and negative signs. Energy also possesses the quality of permanence, and it has the supreme advantage that all natural phenomena can be grouped in an orderly fashion by means of the conception of energy as an entity, and it embraces, not only the conception of substance, but also that of causality. The definition chosen for energy is "work, and all that arises from, or can be converted into, work." If the amounts of energy which result when one kind is completely converted into any other kind be termed equal, then Julius Robert Mayer's law that "during any change the total amount of the energies present remain unchanged" holds. The object of the book under review is to construct a scheme of the world by the exclusive use of the concept of energy, instead of the concept of matter.

The next chapter treats of the various forms of energy in a manner which will be familiar to those who have read Ostwald's "Allgemeine Chemie." There are here

some thoughts which appear to me new. For example, the question is asked, How comes it that all things which we know on this earth possess at once elastic energy as well as weight? The answer is, that it is conceivable that by a process of elimination all things which have no weight have left our universe; for the slightest impulse would send them on a road into space, never to return. A similar suggestion is put forward to account for the coexistence and the proportionality of mass and weight, and matter is defined in terms of energy as a portion of space in which a number of kinds of energy coexist. In reply to the question, Why do they coexist? it is answered that if they did not coexist we should be without knowledge of that portion of space; they *may be* there singly, but if so they elude our senses or methods of detection.

Ostwald claims for this method of regarding Nature that it is free from hypothesis; that each conception necessary for it has a demonstrable and measurable capacity and intensity; and that nothing is stated which cannot be tested by experiment and measurement.

It is impossible, in the limits of a review like this, to follow the author in his contest with the "mechanical explanation" of natural phenomena. An idea may be gained of his method by the quotation,

"Had our researches dealt originally with heat instead of with mechanics, we might be reading books with such titles as 'Motion Regarded as a Mode of Heat'; and there is as much justification for this title as for the ordinary version."

Indeed, the phenomena of radiation begin to be regarded as rapid alternations of conversion of electric and magnetic energies into each other, and in this the pictorial or mechanical idea is almost, though not completely, abandoned and replaced by an energetic interpretation. "Explanations," in the sense of pictorial analogies, are bound in the long run to be fallacious, and only those elements actually present in the phenomena should appear in its representation. As an illustration, it may be said that, in spite of our knowing much about the relations of bodies towards one another from an electrical standpoint, we are nevertheless ignorant of the "nature of electricity." To this it is answered that when we are acquainted with all such relations we shall know as much of the "nature of electricity" as is possible.

Among the laws of energy are to be found the following:—Every equalisation of energy requires time for its accomplishment; no equalisation (Ausgleich) can ever be complete. Only such energies can maintain themselves as distinct phenomena in space which, when coupled with others, maintain a compound equilibrium in which an increase of intensity of the one form is compensated by an equivalent increase of intensity of the other. In order that anything may take place, uncompensated differences of intensity must be present; the uncompensated excess will act as if it alone were present; the weight hung from the spring will fall, unless it is completely compensated by the tension of the spring; the spring will shorten, if the weight is not heavy enough to keep it in equilibrium.

While the happening of an *occurrence* is the resultant of differences of intensity, what we term "matter" is closely connected with capacities. The reason of this is that chemically equivalent quantities or, in other words, chemical capacities are either equal to or bear some simple relation to other capacities.

In treating of causality, Ostwald accepts Schopenhauer's view that the mind is conditioned by the necessity of ascribing a cause to all occurrences, as it must regard them as existing in time and space; but as with time and space, he regards this condition as inherited. From the point of view of energy, one form of energy is to be regarded as the cause of another kind, into which it is transformed, and it is to be noted that in such a transformation energy of higher intensity is always converted into energy of lower intensity. In the case of compensated energies, as, for instance, with a coiled spring, the cause may be regarded as the small amount of energy necessary to release or discharge it, that is, the removal of the compensation of energies at one place. Another group may be referred to a state in which the velocity of change is insignificantly small; an accelerator may be introduced, thus acting as a discharging agent. Changing his point of view, Ostwald suggests that the law of causality is nothing more than another aspect of the process of forming a concept. For this implies placing together things which display agreement in properties, and this "synthesis" may result either in the invention of a name or in the statement of a law of nature; the applicability of this concept in new cases depends only on our skill in originally forming the concept. Passing to the discussion of "necessities of thought" and applying them to the laws of logic, the question is not, Are such laws inherently necessary? but, Are our concepts in general, and among them the laws of logic, fitted to represent the sum of our experiences?

The phenomena of life next come under review. Ostwald regards as the special characteristic of living organisms self-preservation, that is, the preservation of a "stationary" form of existence; the organism must preserve its normal state by maintaining uncompensated differences of intensity by continuous expenditure of energy, and it does this by making use by its own act of previously stored supplies of energy. Reproduction is regarded as a special case of self-preservation. The stores of energy, thus utilised, are mainly chemical, and it is incidentally remarked how much more easily chemical energy can be stored than any other form. The rate of change is regulated by three methods—first, by control of temperature; second, by introducing reagents only where they are required; and third, by the use of "catalysers," that is, of substances which have the power of accelerating or of retarding chemical change. Inasmuch as time is not a factor in chemical energy, the retarding or accelerating action of catalysers requires no "explanation." It is perfectly natural to suppose that the presence of foreign bodies may exert influence as regards the rate of the conversion of chemical energy; on the other hand, if the atomic hypothesis be accepted, it is by no means evident why the motion of the atoms should suffer change by the introduction of a substance which, as it remains unchanged during the conversion of chemical energy, brings no "force" to bear capable of accelerating or retarding the supposed atomic motion.

In the chapter on the "Purpose and Means of Life"

the Darwinian theory is alluded to, and the word "fitness" (Zweckmässigkeit) is defined, with regard to life, as that which increases its duration. And "fitness" consists in the organism being provided with means for spreading, by multiplication, over a wide area, and in its possessing a large store of energy. These conditions are fully discussed in a most suggestive manner. Passing on to the nerves and their functions, it is noticed that the transfer of energy through a nerve is not dependent on the nature of the stimulus which is applied; thus a mechanical, electrical or chemical stimulus, that is, the expenditure of any one of these varieties of energy, is equally effective in causing a flow of energy through a nerve. Ostwald therefore throws out the suggestion that a special form of energy must be associated with all nerve-processes, which he terms "nerve-energy." He regards it as probable that the passage of energy in a nerve is due to the presence of catalysers, which are brought into action by the nerve-energy; these are partly destroyed by their action, so that the nerve fails to respond after it has undergone excess of stimulation. But with rest the catalysers are replaced in even greater amount than originally, and the nerve gains power by use. Organisms, in general, store energy in a chemical form, and their chief function is the conversion of this chemical energy into other forms. As a means of effecting this change they employ catalysers in order to accelerate useful changes and to retard those which are baneful. Closely connected with this idea is memory, which, according to E. Hering, may be defined as that property of living substance by means of which processes which take place in them leave effects which are favourable to the repetition of such processes. Without insisting on the justice of his suggestions, Ostwald adduces a number of chemical processes in which repetition renders the chemical change easier and more rapid.

Passing next to the consideration of the life of the soul or intellect (das geistige Leben), Ostwald takes the view that in all intellectual processes another kind of energy takes part, which he terms "spiritual" (geistige) energy. He is disposed to regard this as identical with nerve-energy, and consciousness is a property of this form of energy when its seat is the brain. Again he illustrates by an analogy; extension in space is a sign of mechanical energy and duration in time of energy of motion. Indeed, he surmises that as the processes of consciousness are themselves associated with a special kind of energy, our views of external nature are therefore legitimately energetic. One is reminded, however, of Dr. Johnson's dictum, "Who drives fat oxen must himself be fat"; at all events the idea is an ingenious one. Consciousness need not always, however, be associated with the occurrence of a process involving nerve-energy; while we have conscious impressions, conscious thoughts and conscious acts, these may also occur unconsciously. It must be admitted that some explanation is required of unconscious thought; anyhow, the author makes out a fair case for the belief.

To follow the author in his discussion of personality, of will and its freedom, of pleasure and pain, of art, of music and of goodness would occupy much space. I hope that even the very imperfect sketch which has been attempted will prove sufficient to induce students both of science and of philosophy to read for themselves this interesting work, and to examine, without prejudice, Ostwald's interpretation of the facts of Nature.

W. R.

THE CIVILISATIONS OF THE OLD AND NEW WORLDS.

The Fundamental Principles of the Old and New World Civilisations. By Zelia Nuttall. Being the second volume of the *Archaeological and Ethnological Papers of the Peabody Museum.* Pp. i+602. (Cambridge, Mass.; London: Quaritch; Leipzig: Hiersemann, 1901.)

THE interesting volume before us is, we believe, the first which any writer has devoted to a careful study of the common principles which underlie the civilisations of Egypt, Babylonia, Mexico and Europe, and as such it merits much consideration at the hands of ethnographers and anthropologists, and of students of religion in general. Much is known about European civilisation, both in its early and middle forms, and something is known of the great civilisations of Babylonia (Sumerian) and of Egypt, but Mrs. Nuttall, in bringing together the results obtained from the study of these subjects during recent years, and in putting them into line with a new group of results obtained from an examination of the Mexican inscriptions at first hand, has done a piece of good and useful work which will be appreciated by all serious students of the beliefs of primitive man. The books which have appeared in Europe and America on early symbolism and cognate subjects are many, but in most of them the writers have confounded what ought to have been kept apart, and owing to a want of groundwork of facts have been led to make nebulous theories which have earned for their authors the ridicule of the trained investigator of such subjects. There is no study more fascinating than that which results in the bringing together of the facts which are common to all great civilisations from China to Mexico, and there is probably none in which so many men have gone astray; every earnest worker knows why this has happened and deplores the publication of books and articles by faddists and others which will obscure the true light.

Mrs. Nuttall's work may be conveniently divided into three sections, which deal with the civilisations of America, Asia and Europe respectively, and these are followed by a fourth section, which treats of civilisations in general; the remainder of the book contains three appendices and an index. As was to be expected, nearly one-half of the volume is devoted to the description of American civilisation, and it is this section in which the archæologist will probably be most interested. Originally the author intended to produce a short monograph of forty-one pages, which treated of the origin of the native swastika or cross symbols, but having actually written the monograph she arrived at the conclusion that the cosmical conceptions of the ancient Mexicans were identical with those of the Zuñis. It was next clear to her that the same fundamental ideas were to be found in Yucatan, Central America and Peru, and the natural result of her investigations into them was that Mrs. Nuttall's monograph of forty pages grew into one of 284 pages, and that then she found a course of comparative studies would be necessary if the best use was to be

made of her previous labours. Unfortunately, Mrs. Nuttall began to print before she realised the magnitude of the task which she had undertaken, and it was impossible, therefore, for her to avail herself of the results of the study of symbols, &c., given by the late Mr. John O'Neil in his "Night of the Gods," by Mr. Elworthy in his work on the "Evil Eye," and by Mr. Frazer in his "Golden Bough." There is, however, little cause to regret this, for by works of this kind Mrs. Nuttall would certainly, though unconsciously, have been influenced, and it is probable that she might have been tempted to modify some of her views as the result; but as it is we have her unbiased opinions placed before us, and this is what is wanted at this stage of the study of primitive beliefs and symbolism. Many years must elapse before the final work can be written on these subjects, for all the materials upon which it must be based have not yet been collected, and until this is done it is futile to attempt to deduce the "conclusion of the matter."

Starting with the discovery that the great Mexican god Tezcatlipoca was identical with Mictlantecuhtli, and that having been overthrown by Huitzilopochtli he arose and transformed himself into the constellation of Ursa Major, Mrs. Nuttall goes on to show by a series of cuts that the constellation of Ursa Major furnished the archetype of the different forms of the swastika and cross symbols. The next point to determine was at what epoch the swastika was used as a symbol, and this Mrs. Nuttall decides could not have been before Ursa Major became circumpolar, *i.e.* about B.C. 4000.

"At that period, when Draconis was the Pole-star, the circle described about it by Ursa Major was considerably closer than it is at present" (p. 21).

At a very early period, Mrs. Nuttall thinks, Polaris came to be regarded as an immutable centre of axial energy, and in process of time as the symbol of the Creator of the universe. The rotary motion of Ursa Major was next observed carefully, and eventually the different positions of the constellation became associated with the seasons, and the swastika was commonly employed as the sign for year, or for a cycle of time.

But besides the swastika another calendar sign is known, *i.e.*, that which is a representation of the night of the winter solstice, the well-known triskelion; examples of the swastika are common among the ancient Mexicans, while of the triskelion there are none. The constellations of Ursa Major and Ursa Minor each contain seven stars, and this mystical number appears in the seven tribes of the ancient Mexicans who traced their origin to seven caves situated in the north, and in the seven parts into which Cosmos was divided. The first of Cosmos, or fixed centre, was Polaris, creative, generative and ruling power of the universe; its Four Quarters were associated with the elements and were ruled by the central force, and the ideas of Above and Below, which are found in Egyptian and other ancient languages, were suggested by the rising and setting of celestial bodies.

The Mexican religion being of a character so decidedly astronomical, it follows that everything connected with the worship of the great god would partake of the same nature; pyramids and temples were just as much astronomical observatories as houses of God, and their construction was planned accordingly. The people who held the views described above believed that they were descended from star deities, and they had a legend that the goddess "Starry Skirt," having been united to "Shining Star," gave birth to a flint knife, called Tecpatl. Their other children were startled at this, and, seizing the flint knife, hurled it to the earth, when it broke into pieces at the "Seven Caves" and produced 1600 gods and goddesses. It is worthy of note in connection with this that the flint knife was called the son of Cihuacoatl, the earth-mother. As befitted a religion which was based upon the cult of the night sky, at least one-half of the ceremonies were performed during the night; the sacred fire burnt by day and by night, and was only allowed to go out once every fifty-two years. But it was rekindled at midnight precisely.

We regret that we cannot follow Mrs. Nuttall step by step through her deductions from the Mexican picture signs and her description of primitive customs and beliefs as illustrated by them, for to do so would require the space allowed for several articles; the reader must do this for himself, and we are justified in saying that he will be rewarded for his pains if he does so. The astronomical origin of nearly every habit and custom of the ancient Mexican is clearly traced, and the relative position of the sexes in the State, as well as the classification of the people for administrative purposes, are well delineated; in short, what Mrs. Nuttall has given us is a detailed history of the ancient Mexican and his civilisation. The references to inscriptions throughout the work prove that she is familiar with what is known of the meaning of Mexican picture signs, and many of her facts are based upon the results given by Mr. Alfred Maudslay, but we are glad to see that whilst Mr. Le Plongeon is quoted at times, Mrs. Nuttall does not in any way identify herself with his wild views about the Maya language.

Passing from American to Chinese civilisation, Mrs. Nuttall has collected a large number of notes and passages from which it is seen that the Chinese held views about Ursa Major, the Four Quarters of Heaven, the Above and the Below, &c., very like those which were held by the ancient Mexicans, and it is remarkable how close is the similarity between the habits and customs and religion of the two peoples in certain respects. The really interesting point in connection with such similarity is to account for its existence; at present it is impossible to do this, and we do not see that the difficulty is in any way lightened by the theory which makes the Chinese to come originally from Babylonia, which country the emigrants are said to have abandoned when Kutir-Nakhkhunte conquered Babylon, B.C. 2295. The identity of Chinese and Akkadian has not been demonstrated to the satisfaction either of Chinese or Akkadian scholars in general, although it was fashionable some few years ago to declare that the two languages were one and the same tongue; the theory was not entertained by any except Chinese scholars who knew no Akkadian, or by men who knew a little Akkadian but had no knowledge of Chinese. The remarks on the entrance of Buddhism into China in the first century of our era are to the point, and the extracts from the famous bilingual Syriac and Chinese inscription (p. 304) at Singanfu which Mrs. Nuttall quotes contain interesting

confirmation of her views of the Christian cross being originally related to the swastika. The Chinese, taking this view, naturally called the Christians "Cross-worshippers." In Japan and India Mrs. Nuttall has found many parallels, and in Mesopotamia to this day the men of Saba appear to worship the Pole-star. The religious literature of ancient Babylonia and Assyria contains many passages which prove that the Semites who employed the cuneiform character held many views in common with the Mexicans; while an elaborate examination of Egyptian works has provided Mrs. Nuttall with a large number of proofs that in Mexico, China, and Egypt the views held in respect of certain astronomical phenomena were identical.

One of the most interesting sections of the book before us is that which treats of civilisations in general, and which contains Mrs. Nuttall's general summary and conclusions about the meaning of the facts which she has so diligently compiled. To detail these would greatly lengthen an article which is already inordinately long, and the reader will, no doubt, prefer to peruse these for himself; but we may briefly point out that the central idea of the work is that the swastika, which was first employed as a year sign, became later the symbol of the Four Quarters, of quadruplicate division, and of a stable central power, whose rule extended in four directions and controlled the entire Heaven. Human society was divided into four groups, and territorial organisations were formed in four parts. Early civilisations were founded on astronomical principles, on which also rested the worship of the gods. In the case of America, certain elements of culture are assumed to be due to "Mediterranean seafarers" and to transported refugees and would-be colonists; the basis, however, of both foreign and native civilisations was the recognition of immutable laws governing the universe, "attained, by both races, by long-continued observation of Polaris and the 'northern' constellations." The use of Mrs. Nuttall's volume is much facilitated by the excellent index, which fills thirty-four pages of matter printed in double columns in small type, and which merits great praise. We could have wished that a bibliography had been added and more references to the public literature of early symbolism; to say this is not to detract from the commendation which the book justly deserves, for a classified list of authorities could be compiled from Mrs. Nuttall's notes, and it would be useful to everybody interested in the subject.

GEOMETRY—NOT IN EUCLID'S ORDER.

Primer of Geometry, comprising the Subject-Matter of Euclid I.-IV., treated by the Methods of Pure Geometry. By H. W. Croome Smith, B.A. Pp. xvi + 100. (London: Macmillan and Co., Ltd., 1901.) Price 2*s.*

THIS little book is another attack on Euclid, and its main object is to exhibit an elementary course of geometry in a system of natural sequence—Euclid's order and method being, of course, ignored. Although in the preface the author adopts a severely logical style and successfully maintains a strong case against our conservative Euclidians, it seems to us that in one respect he is in error. His work is divided into three chapters, headed "Straight Lines and Rectilineal Figures," "The Circle," and "Areas." In the first chapter no mention of a circle occurs, and the author taxes Euclid with an illogical mode of procedure in the following words:—

"It is at least questionable logic to make use of the circle in the early stages, and subsequently to use the properties thus demonstrated of lines, angles, &c., in demonstrating the properties of the circle."

Justice to Euclid compels us to maintain that this charge is substantially unjust, because the only use made by him of the circle in the early stages (Book I. of Euclid) relies on the facts that the radius is a line of constant length, and (in prop. xii. of Book I.) that if a circle cuts a right line once, it will cut it again. No one can quarrel justly with these assumptions, or can seriously describe them as involving "properties" of the circle which require antecedent demonstration. When criticising Euclid, we must remember that geometry is not wholly a system of pure or formal logic—it implies the sense of sight, sensuous intuition in space.

One disadvantage of ignoring the circle wholly in the early stages, as is done by Mr. Croome Smith, is that we get into serious difficulties with regard to the conception and measurement of *angles*. He identifies an angle with "change in direction"—"this *change in direction*, which has nothing to do with the length of the line, is what we mean by *angular magnitude*" (p. 6); "the angle is *measured* by the amount of revolution of a straight line when turned about the vertex in the plane of the lines from the one to the other." True; but how are we to get a quantitative meaning of the word "revolution" itself? It is, without the aid of the conception of a divided circle, or of a system of superposition, just as vague and undefined as Euclid's own term "inclination." It appears to us that Mr. Croome Smith wrestles vainly with a definition of a right angle on p. 7. He imagines a right line OA to revolve round O into the position OB, which is OA reversed, and he says,

"in the position OC, midway between OA and OB in the course of its revolution, the turning line makes with OA or OB an angle which is half the preceding angle: such an angle therefore is also an angle of *constant* magnitude, and is called a right angle."

In this definition there is one little word—"midway"—the precise meaning of which we should wish to know. We fear that it is hopelessly vague without the notion of a circular protractor, or something more than the author is willing to give us. Hence we think that his definition of an angle and his method of measuring angular magnitude are not successful.

Nevertheless, criticism of this kind must not condemn a book which has several merits. A judicious teacher will always be able to supplement imperfect definitions. There is, perhaps, far too much straining after completeness of definition and verbal exactness in writers on geometry; for some of the most simple notions in the subject are things which cannot be defined with absolute accuracy, and the writer as well as the teacher must take it for granted that the pupil has already an adequate notion of the thing described—*e.g.*, a point, a right line, a plane surface.

Mr. Croome Smith rightly discards Euclid's limitation

that we must make no use of the bisector of an angle or of a line until we have shown how to draw the bisector. Fancy anyone laying down the law for Clerk Maxwell that he must make no investigation of the electromagnetic theory of light until he has demonstrated the reality of the ether! By ignoring the restriction, Mr. Croome Smith is enabled to replace the usual proof of the Asses' Bridge proposition by one much simpler.

All the *problems* of Euclid (to bisect an angle, to draw a perpendicular to a line from a point without it, to draw a tangent to a circle, &c.) are kept by themselves in a section at the end of the book. The author's proofs leave nothing to be desired on the score of simplicity, and his little book will be of much value to any committee that may be formed by the Universities or the British Association for the purpose of providing an easy and natural course of geometry for use in our schools.

We cannot refrain from calling the author's attention to the *form* of such a statement as (p. 31): "A rhombus, and therefore a square, are equilateral." This is followed by one of similar arrangement; and in line 12 from the end of p. viii, "is implied" should be "are implied."

OUR BOOK SHELF.

The Small Farm and its Management. By James Long. Pp. xvii + 281. (London: Smith, Elder and Co., 1901.) Price 6*s.*

MR. LONG starts with the idea that it is very desirable for the purpose of maintaining a vigorous rural population that the number of small farms cultivated by their owners should be considerably increased. Nearly everyone will probably agree to this proposition. When, however, we learn the conditions needed for the success of the small farmer, and which are plainly set forth by the skilful writer of the present book, we become more and more convinced that the extent to which successful farming of this kind can be developed under present conditions is very limited.

Mr. Long tells us that for a successful twenty-acre farm, third-class land must be refused at any price; that second-class land should only be occupied by highly skilled men with sufficient capital; and that first-class land should, if possible, always be selected for such a holding. The land must, further, be situated near a railway, with easy access to a large consuming population. Such land, Mr. Long frankly tells us, will generally be found already occupied, and could not be purchased save at a high price. His ideal farm is, further, to have one-half of its area in permanent grass, and to possess an acre of orchard. It must, of course, have a dwelling house and farm buildings, with a suitable access to a road. How can all these special conditions be provided except at a prohibitory cost?

When we pass to the details of the management which is to result in a handsome profit to the owner, we discover that he is supposed to be no mere agricultural labourer, but to excel both in knowledge and judgment the average farmers of the country. His farm of twenty acres is to carry one horse, four cows, a breeding flock of ten ewes, two sows and their offspring, eighty hens and forty turkeys, and is to produce for sale twenty-four quarters of oats, twelve tons of potatoes, and the fruit from an acre of orchard. His four cows are to be chosen and managed with such judgment and skill that they will yield 3000 gallons of milk every year, a quantity far above the average. His hens are to lay twice the number of eggs usual in poultry yards. Everything on the farm is assumed to be first rate and thoroughly successful. The result of this splendid management is to be a profit of 120*l.* per annum. Years of drought, or other agricultural disasters, are apparently not supposed to occur. It will naturally be asked, if a profit of 120*l.* can be made on twenty acres, why should not an annual profit of 1200*l.* be made on a farm of 200 acres worked on the same lines? And if such is the value of the land to the occupier, at what price can it be purchased?

Whatever opinions we may form as to the possibility of creating a system of small farms, or as to the prospects of their profitable cultivation, we can form but one opinion about Mr. Long's book. It is well done, and supplies a large amount of information on a great variety of subjects which cannot fail to be of value to all who are seeking to make a profit out of a small holding.

R. W.

L'Huître Perlière, Nacre et Perles. Par L. G. Seurat. ("Encyclop. Scient. des Aide-Mémoire"). Pp. 194. (Paris: Masson et Cie.) Price 2 fr. 50 c.

THIS is a useful little book of close on 200 pages and a few illustrations, in which the author—whose name was already known in connection with pearl oysters—has brought together the leading facts in regard to the molluscs, of both sea and fresh waters, producing pearl and mother-of-pearl. The introduction shows that the book has been written mainly in the interests of the French nacre industries, which the author regards as of great national importance. Although London is at present the great market for pearl shell, we are told that "La France possède, en effet, les plus vastes bancs d'huîtres perlières et nacrières qui soient au Monde, dans ses colonies d'Océanie," and the author evidently desires to stimulate the exploitation and cultivation of the French pearl industries at Tahiti and other Pacific stations. But still, the descriptions of animals and fisheries have been drawn from all parts of the world, and, in fact, most attention is given to the oyster (*Meleagrina fucata*) of Ceylon and British India on the well-known banks of the Gulf of Manaar.

M. Seurat points out on more than one page the gaps in our knowledge of the nacre-forming molluscs, and wisely insists upon the necessity of a thorough examination of the structure, life-history and habits of the Meleagrinas before it is possible to establish a rational regulation of the fisheries. The scope of the work may be gauged by the following summary of the contents of the chapters: Anatomy and biology of the pearl oyster and of other molluscs that produce pearls or nacre; the pearls, their position, structure, chemical composition and experiments as to their production artificially; the fisheries both in the sea and also in the rivers of Europe and America; commerce and industries; and, finally, pearl-oyster cultivation. In his conclusion our author sums up that "l'ostréiculture perlière est une chose possible, qui est susceptible de donner des résultats pratiques," and draws a rosy picture of the prosperity that would attend the lagoons of Tahiti under a rational exploitation of this new industry. So may it be.

Voices of Nature and Lessons from Science. By Caroline A. Martineau. Pp. 160. (London: Sunday School Association, 1901). Price 1*s.* net.

MISS MARTINEAU describes clearly a number of simple scientific facts, mainly concerning natural history subjects. She thus assists the extension of a knowledge of nature among those who are greatly in need of it. The prominence given to Darwin's teachings—a large part of the book being taken up with the elementary principles of evolution—is a very commendable characteristic. The spiritual lessons to be learnt from natural phenomena may be "skipped" by readers who prefer to deal with ethics apart from natural science.

LETTERS TO THE EDITOR.

The Quadrantid Meteors, 1902.

ON the night of January 3 some fine meteors were observed here. It is doubtful, however, if any of them were directly connected with the radiant that has given this early January shower its name. Possibly the first meteor observed shortly before ten o'clock may have issued from the neighbourhood of Boötes, as it shot upwards from the direction of the Great Bear with a brilliancy sufficient to attract attention in a lighted thoroughfare, from where, however, its starting point could not be clearly ascertained. During a watch kept under more favourable conditions for observation, between 10.30 and 11.30 G.M.T., four or five shooting stars were observed, the brightest of which scarcely equalled a second magnitude star, its path extending from Gemini to the east of Ursa Major. The others were seen flashing to the east of the latter constellation with no well-defined centre of radiation. It should have been stated that in a ten minutes' watch between 10 and 10.30 a stationary meteor more brilliant than a first magnitude star appeared for about half a second midway between the Quadrantid radiant and Ursa Major. This was the only meteor seen that may perhaps be regarded as comformable to the radiant proper, though almost exclusive attention was given to that part of the sky. Though occasionally a look out was kept from 12 to 1 a.m., no shooting stars were seen, but in an unbroken watch from 1.15 to 1.45 a.m. a brilliant bolide was observed at 1.40 gliding down evidently from the neighbourhood of Gemini towards the Great Bear, and throwing off several fragments near the end of its path. It was the brightest meteor seen during the night. The night of the 3rd was very fine here, though a few clouds interfered somewhat with observation between 10 and 10.30.

Similar atmospheric conditions obtained in the first half of the night of the 4th, and an early watch for Quadrantids was maintained between 10 o'clock and midnight. Six or seven meteors were observed during this period. The first seen at 10 p.m. shot down through Orion at a great rate from some point considerably higher up, the exact whereabouts of which could not be known, as the meteor was only accidentally glimpsed. It must have been of a magnitude equal to Sirius. Another meteor (second magnitude) passed from a little below Gemini to Ursa Major at 10.45, and yet another from the same radiant centre to Leo at 11.45, the latter being of more than first magnitude brightness. This upper radiant must have been at the least fairly active, as the above meteors were only accidentally seen, persistent observation being maintained towards Boötes, which, however, as yet met with scant success, only a few meteors having been noticed, all below the second magnitude with the exception of one in the form of a brilliant flash, which shot straight from the direction of Boötes, but made its first appearance considerably to the east of that constellation, its course being parallel to the horizon. No definite centre of divergence could be assigned to the rest.

During a subsequent watch held between 12.45 and 1.15 there seemed to be a period of meteoric quiescence, but when the outlook was resumed at 1.30 a distinct change had evidently taken place in the interval. Bright meteors were shooting steadily from the last two stars in the tail of Ursa Major. The radiant seemed very accurately defined there at a point midway between the stars in question and very slightly to the east. From 1.30 to 1.45 five meteors issued from this centre ranging between the second and third magnitudes. During the same time also three second magnitude shooting stars came down towards Ursa Major, evidently from the upper radiant, whose activity had drawn attention to it earlier in the night, and which was now in active cooperation with the radiant centre lower down. Further observations, however, could not be obtained as regards the progress of the display, as light clouds at 1.45 a.m. began to obscure the sky, obliterating all but the brightest stars, which continued to shine dimly for a while, during which an occasional flash of a meteor was seen; but eventually the heavens became a starless blank, and the watch had to be abandoned. Whether, therefore, the radiant proper of this shower developed any symptoms of activity as the night wore on and the time of the expected maximum drew near could not be ascertained here. In view, however, of the sudden appearance of the radiant in the tail stars of Ursa Major, this may not have been improbable, the more especially as there are reasons for believing that the maximum of the shower may have occurred one or two hours later than that fixed at 3.30.

It may be observed that the multiple character of the radiant of the meteors of January 2 was particularly noticeable in 1872 (British Association Report, "Luminous Meteors," 1872), when radiant centres roughly corresponding with those on the present occasion furnished more than 50 per cent. of the meteoric shower observed in that year. JOHN R. HENRY.

Dublin.

Sir Walter Raleigh and Evolution.

I HAVE recently come across a passage in Sir Walter Raleigh's "History of the World" which seems to me sufficiently remarkable for the author to deserve a notable place among those early naturalists who anticipated in some measure the modern views on evolution. In the historical sketch at the beginning of the "Origin of Species" Darwin quotes Buffon, who was born a century and a half later than Raleigh, as "the first author who in modern times has treated the subject in a scientific spirit"; but although, scientifically, Raleigh cannot be compared with Buffon, the fact of his having penned at such an early date the words I am about to quote possesses some interest. The passage I refer to is to be found in the 1621 edition (part i., book i., chap vii., § 9, p. 94). Speaking of the days of the Flood, he says: "But it is manifest, and undoubtedly true, that many of the *Species*, which now seeme differing, and of severall kindes, were not then *in rerum natura.* For those Beasts which are of mixt natures, eyther they were not in that age, or else it was not needfull to preserve them, seeing they might be generated againe by others: as the Mules, the *Hyæna's*, and the like; the one begotten by Asses and Mares, the other by Foxes and Wolves. And whereas by discovering of strange Lands, wherein there are found divers Beasts and Birds differing in colour or stature from those of these Northerne parts; it may be supposed by a superficiall consideration, that all those which weare red and pyed Skinnes, or Feathers, are differing from those that are lesse painted, and were plaine russet or blacke; they are much mistaken that so thinke. And for my owne opinion, I find no difference, but onely in magnitude, betweene the Cat of *Europe*, and the Ownce of *India*; and even those Dogges which are become wilde in *Hispagniola*, with which the *Spaniards* used to devoure the naked *Indians*, are now changed to Wolves, and begin to destroy the breed of their Cattell, and doe also oftentimes teare asunder their owne Children. The common Crow and Rooke of *India* is full of red feathers in the drown'd and low Islands of *Caribana*; and the Black-bird and Thrush hath his feathers mixt with blacke and carnation, in the North parts of *Virginia*. The Dog-fish of *England* is the Sharke of the South Ocean: For if colour or magnitude made a difference of *Species*, then were the *Negro's*, which wee call the Blacke Mores, *non animalia rationalia*, not Men, but some kind of strange Beasts: and so the Giants of the South *America* should be of another kind, than the people of this part of the World. We also see it dayly, that the natures of Fruits are changed by transplantation, some to better, some to worse, especially with the change of Clymate. Crabs may be made good Fruit by often grafting, and the best Melons will change in a yeere or two to common Cowcummers, by being set in a barren Soyle." AGNES ROBERTSON.

The Old Hall, Newnham College, Cambridge, January 13.

The Teaching of Mathematics.

PROBABLY every experienced teacher of mathematics qualified by a sufficiently thorough acquaintance with the relations of his subject to the physical sciences and practices will have some sympathy with the document which appeared under this heading in your last issue (p. 258). I do not desire to discuss the changes it suggests, I merely wish to describe as a contrast to that or any other rational scheme the work that year by year the public purse pays some of us to attempt. Protests against South Kensington teaching and the South Kensington scheme of work are frequent, but I do not remember seeing any detailed criticism of any part of the course. Here is the work that I and hundreds more teach yearly in what is known as the second stage of mathematics.

In geometry; the second, third and fourth books of Euclid. In algebra; quadratic equations, or indeed any equation, surd or rational, for one or two unknown quantities, except such as ultimately demand the solution of a non-factorial cubic or biquadratic; the simplification of surd quantities and expressions and problems in ratio and proportion.

Trigonometry has to be taught from the beginning through the equations of identity between functions of the ratios and the values of the ratios of the simple angles to the logarithmic solution of oblique triangles, with proofs of the requisite formulæ. A sufficient knowledge of logarithms is demanded from the student to prove the ordinary logarithmic laws—no reference is made in the entire syllabus to the theory of indices—and to prove the numerical laws of characteristic and mantissa belonging to the decimal system of logarithms. He must also be able to adapt and use—for any possible logarithmic computation—a few seven-figure logarithms given at the end of his examination paper, and obtain by means of proportional differences a result corrected to six significant figures.

All this work is to be taught between September and May to pupils who, throughout the country, are generally accorded two hours a week for the subject, and who, as evening students otherwise employed through the day, are seldom able to give much time to study.

In some parts of the course—for instance, the equations set for solution—a pedant's ingenuity is used to find novelty and—for the beginner—difficulty. In other parts—as, for example, the surds and logarithms—the monotony of treatment year by year is one of the mainstays of the examination-teacher.

I have not exhausted the possible complaints against the course. Its first four stages are almost equally bad throughout, though the second is certainly the worst. But I have, I hope, said enough to convince any experienced teacher of the subject under other conditions of the urgent need we feel for changes.

I wish to guard myself against one possible personal imputation. I am not complaining because I have failed; I have been, I believe, at least averagely successful in obtaining the examination-product that South Kensington demands, and I have, I hope, also taught some mathematics. But I protest that my efforts towards the one end should be so severely handicapped by the necessity of attaining the other.

Plymouth Technical School. C. J. FORTH.

Birds Capturing Butterflies in Flight.

MR. MCKAY'S letter in NATURE of January 16 (p. 247) is of interest in pointing out that some butterflies are normally exposed in flight to danger from certain birds. Nevertheless, I believe this to be exceptional so far as this country is concerned. At the present moment I have in my possession a specimen of the day-flying moth *Orgyia antiqua*, which my friend Mr. D. F. Taylor saw seized when on the wing by a house-martin, which relinquished its hold in consequence of a luckily aimed stick from my informant. The left fore-wing shows plainly the mark of the bird's beak, which, however, did not tear the wing, but merely left a triangular area denuded of scales. So far as I am aware, house-martins do not, as a rule, feed on Lepidoptera, and this instance is probably to be regarded as a mistake on the part of the bird. It is possible that other isolated examples of similar mistakes may have been noticed, but their bearing on the general question of the coloration and markings of butterflies must be very slight. OSWALD H. LATTER.

Charterhouse, Godalming, January 17.

An Unusual Rainbow.

ON June 16 last I was at Lucerne, and at about 4 p.m. there was a remarkably brilliant rainbow over the lake. It was, however, unlike any previous rainbow ever seen by me, inasmuch as in addition to the ordinary bow of seven colours there was a second band of orange colour and a second band of purple, added to the other seven colours on the underside, but distinctly part of the same unbroken and continuous band of colour; in other words, it was a bright broad rainbow composed of nine instead of seven bands of colour. I have, since my return, met with no person able to explain this phenomenon. I was quite alone at the time. The rainbow lasted several minutes. It has been suggested to me that possibly some scientific reader of your paper could explain this very unusual appearance; or, at any rate, some other traveller at Lucerne on the day referred to may be able to confirm my description of what appeared to me so very unusual that I should almost have hesitated to accept any other person's description of it. THOMAS FULLER.

Bristol, January 17.

Change of Pitch of Sound with Distance.

IN Mr. West's letter in NATURE of December 12, 1901, he suggests that a lowering of pitch with distance may have been noticed, although his experience has been the reverse. My grandfather, the late Mr. Henry Knaüff, who, during his lifetime, was an organist and organ builder in Philadelphia, mentioned having noticed this lowering of pitch on several occasions. In long churches, with the organ over the front doorway, he claimed that the voice of the celebrant at the altar sounded distinctly flat to a listener at the organ, but on advancing to the altar this flatness disappeared. I have never noticed this myself, but I have not his ear for small differences of pitch.

PAUL R. HEYL.

Boys' High School, Reading, Penna., U.S.A.

TO THE MOUNTAINS OF THE MOON.[1]

MR. J. E. S. MOORE has undoubtedly written an interesting and original book on the lake region of Central Africa, a book which in many respects deserves to rank with that remarkable pamphlet (it was little more in volume) by the late Prof. Drummond on Nyasaland (miscalled in this instance "Central" Africa). Prof. Drummond's journeys up and down the Zambezi-Shire and the length of Lake Nyasa, with a climb on to the Nyasa-Tanganyika plateau superadded, were wholly unremarkable as a work of exploration, but Drummond contrived to see and put into pithy sentences what a legion of African explorers had seen but never expressed before. Drummond's little book should long remain a classic, and many of his expressions are quoted by the more modern African travellers with force, but without acknowledgment. Mr. Moore avows his indebtedness to Drummond on more than one occasion, but his own work is quite as original in its way, though perhaps dashed with a spitefulness which was absent from Drummond's writings. Mr. Moore's book is a true account of what he has seen, but a partial one, that is to say, he has told no untruth, but he has left untold at least a third of the whole account. In order to be original, in order to counteract the rather wearisome optimism of most works of African travel written during the last ten years, he has been careful to insist on all the faults which a white man may legitimately find with the climate, soil and insalubrity of Central Africa. He deliberately ignores much that might be permanently attractive to the European settler, much that is profitable to European commerce, and much of the good that has been done by European pioneers, whether Government officials, missionaries or traders. It is a pity in some respects that Mr. Moore's work is not complete, that he should have striven so much after originality as to refrain from writing a perfectly balanced book conveying an impartial verdict. It is, perhaps, best and fairest to regard Mr. Moore's work as a "two-thirds" book, a description giving two-thirds of the whole truth and leaving the reader to supply the missing third from the many other publications describing East-Central Africa between the White Nile and the Zambezi which have appeared since 1890. There is no doubt that Mr. Moore is eminently readable; he is so interesting that his occasional descents into sheer flippancy and his carelessness in the spelling of names may easily be forgiven, except, perhaps, by those whose names are incorrectly spelt! By a curious fatality there is scarcely a single European surname or a native place-name of any importance in the whole book which is not incorrectly spelt.

1 "To the Mountains of the Moon." By J. E. S. Moore. Pp. xvi+350. (London: Hurst and Blackett, Ltd., 1901.)

The illustrations supplied to the work consist of photographs and drawings, the latter singularly vivid if occasionally crude. Mr. Moore succeeds almost better than any other African traveller whom we know, able to use pen and brush, in giving an idea of the wonderful cloud effects to be seen in these African skies. We have stigmatised his black and white drawings as crude—as such they must appear to the ordinary European—yet in extenuation of their hard light and shade must be quoted the undeniable fact that there is something about the African atmosphere which gives these violent effects. A vivid (and the reviewer is able to say a truthful) picture is that facing p. 76—"Storm-clouds, Mountains and Bananas on the East Coast of Tanganyika."

As regards the scientific results of Mr. Moore's expedition—the point of view from which most readers of NATURE will be interested or uninterested in the book—we are able to say very little, because Mr. Moore is reserving his reports on his biological studies for another volume. The chief matters of interest to scientific students of Africa in the work under review consist of the ascent of the still active volcano of Kirunga cha gungu and a plucky attempt to ascend one of the summits of the Ruwenzori range. Interesting observations were also made on and around Lake Kivu; and Mr. Moore's opinion that this lake was probably once connected with Albert Edward and the Nile system rather than with Tanganyika and the Congo, but that the severance between Kivu and the Nile in the Albertine Rift Valley occurred through the uprising of the Mfumbiro volcanoes, is probably correct. It is certainly original. The lacustrine fauna of Kivu is apparently similar to that of Albert Edward, and quite distinct from the remarkable marine fauna of Tanganyika.

With regard to Mr. Moore's attempted ascent of the Ruwenzori range, furnished with guides by Mr. Bagge, the Government official at Fort Portal (a place which Mr. Moore persists in calling Fort Jerry), he attacked the mountain by the Mubuko Valley. According to his own account he probably reached a total altitude of 14,900 feet. Sir Harry Johnston, who ascended the mountain some months later, tells us that he, following the same route, could get no higher than 14,800 feet. Subsequently Mr. Wylde, of the Uganda Administration, also reached a point which he describes as under 15,000 feet in altitude. As Mr. Moore's and Mr. Wylde's observations were only taken by aneroid whereas Sir Harry Johnston's was by boiling-point thermometer, it is probable that all three explorers reached the same spot in total altitude, all being stopped there by the same obstacles of rocky precipices. Mr. Moore believes that the spot he reached was on the actual ridge of Ruwenzori, from which, theoretically, one might look down on the Semliki Valley or on Eastern Toro. Now from Sir Harry Johnston's observations, as given in his lecture of November 11 last, and his paper recently published in the Geographical Society's magazine, it is clear that this altitude of just under 15,000 feet is nowhere near, is

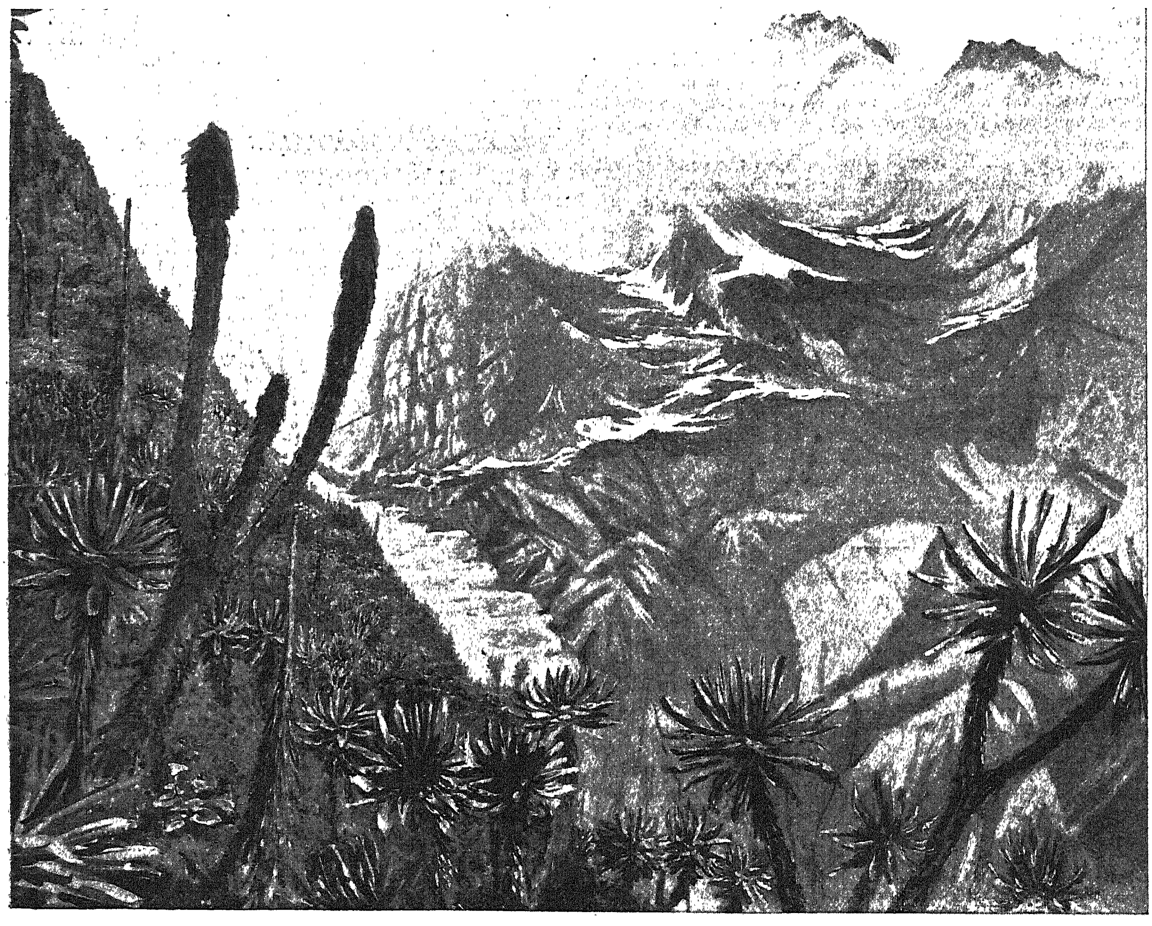

FIG. 1.—View of the small glacier between the Northern Snow Ridge of Ingomwimbi and Kanyangogwi from the former, at a height of 13,600 feet.

perhaps a couple of thousand feet below, the top of the ridge which connects all the Ruwenzori snow-peaks. Assuming this ridge to be at something like 17,000 feet in altitude, the high peaks of Ruwenzori would again rise two or three thousand feet higher, and thus the supreme altitude of 20,000 feet of the highest point of Ruwenzori which has been predicted by Major Gibbons, Sir Harry Johnston, Mr. Wylde and others is more likely to be nearer the ultimate truth than Mr. Moore's assertion that the greatest height of Ruwenzori is probably not more than 17,000 feet in total altitude.

Mr. Moore makes some very interesting remarks on the causes which probably led to the formation of the park-like scenery so characteristic of tropical Africa. On recently formed alluvial flats those strange and hideous fleshy euphorbias commence to grow on what is, to begin with, a shadeless, sandy wilderness, where all seedlings which might form forest trees are burnt up and withered by the scorching sun. The euphorbia, however, resists the sun's rays, being distinctly a plant of the desert. As its candelabra branches increase in numbers and spread out to the right and left they create shade, while the fallen branches decay and form vegetable soil. Under this protection and by this nourishment seedlings of palms and forest trees survive and flourish. When they have got a good hold on the soil the original euphorbia is long since dead or hidden, and the park-like clumps of handsome trees have become a permanent feature over what was once a wind-swept, sun-scorched, barren plain.

We strongly recommend Mr. Moore's book to the attention of all who are interested in tropical Africa. His pessimistic description, however, of the future prospects for European trade with these countries can be easily corrected by a glance at the statistics issued by the African Protectorates. Countries the trade of which has risen in a few years from an annual value of 30,000*l.* to a quarter of a million, while their local revenue has grown from nothing a year to 50,000*l.* or 60,000*l.*, cannot be such hopeless investments for European commerce and enterprise as Mr. Moore would have us believe.

Mr. Moore was accompanied on his journey by a surveyor, Mr. Malcolm Ferguson, whose surveys are certainly one of the valuable results of the expedition. If Mr. Ferguson is to be regarded as more accurate than his predecessors his work will result in the shifting of the northern end of Lake Tanganyika nearly half a degree further to the west, while he will also have supplied us with the first approximately correct delineation of Lake Albert Edward.

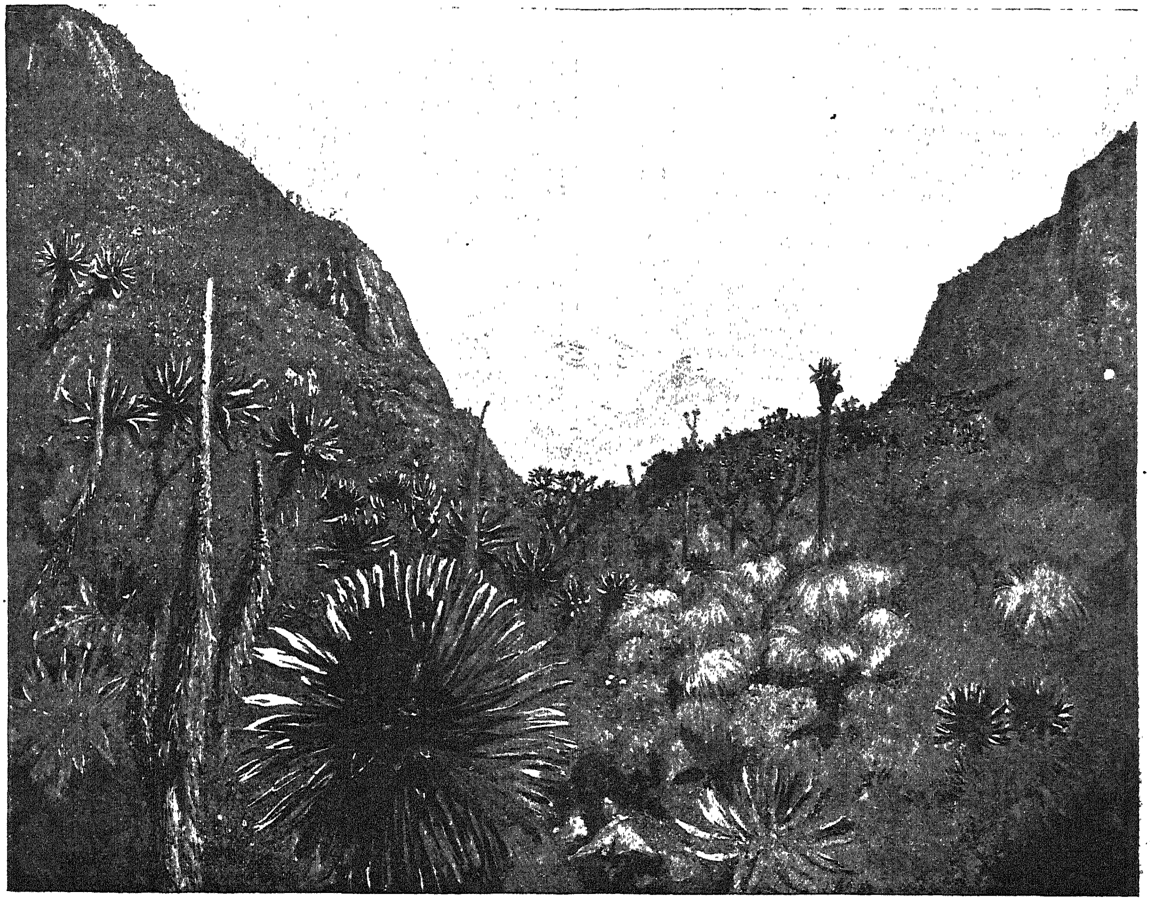

FIG. 2.—The Northern Snow Ridge of Ingomwimbi from a point about 12,500 feet.

THE RECLAMATION OF THE ZUIDERZEE.

IN a recent consular report from the Netherlands, issued by the Foreign Office, reference is made to a Bill which was introduced in the Second Chamber of the States General, for the purpose of obtaining authority to carry out the works required for the first portion of a scheme for reclaiming 800 square miles of land from the Zuiderzee, and for raising the necessary funds, estimated at eight million pounds, the cost of the entire scheme

being put at $15\frac{3}{4}$ millions. A translation of the Bill and explanatory memorandum of the Minister of the Waterstaat are also given.

This scheme for adding land to the seven provinces of the United Netherlands is only a continuation of those bloodless conquests which Holland has been carrying on for the last twenty centuries, by which, little by little, the cultivated area of the country has been enlarged without annexation, or encroachment on neighbouring countries.

Holland affords the most remarkable example of the operations of Nature in that process of destruction and reconstruction of the earth on which we live that is always in process. The land is almost entirely composed of the off scourings of Swiss, German and French territory washed off the land by the rain, transported several hundred miles by the rivers Rhine, Scheldt and Maas, and dumped by them into the North Sea, until a delta was formed and the shore advanced seaward 130 miles for a width of 60 miles. So long as the storms of the North Sea beat on this delta the fine particles of alluvium were washed away by the waves and carried to the still water of the deeper parts of the ocean, leaving only sand behind. The wind then became an active agent in the making of the land by lifting and transporting shorewards the material off the long stretch of bare sands exposed at low water, and gradually heaping it up in the form of sand hills, constituting that long line of dunes which extends the whole length of the seaboard for 230 miles and forms the main protecting barrier of the land from the incursion of the sea during storms and high tides. The delta thus sheltered and protected became one vast warping ground over which the rivers continued to deposit their burden of rich alluvium, gradually building up a soil of marvellous fertility.

Through the surface thus raised the water poured into the delta found its way to sea through innumerable channels which finally concentrated in three main openings through the dunes. The surface thus became an amphibious country, half land and half water, divided by numerous channels into islands. At the time when historical records begin some of these islands had risen above the level of the tides, and the country consisted of large alluvial plains the greater part below mean sea level, large meres or lakes from 15 to 20 feet deep, and deep winding channels, the whole bordered by the higher plains on the south and east composed of sand and drift.

At this epoch man stepped in to gather the fruits of that which the contending forces of rain and rivers, storms and tempest, wind and tides had produced.

The Roman records afford some outline of the condition of Holland at this time, from which it is known that early in the Christian era the higher diluvial lands, dunes and heaths were occupied by the Batavians, who gained a precarious living by hunting, fishing, and pasturing cattle in summer on the alluvial islands.

Whether the first embanking and reclamation was done by the Batavians or by the Romans is uncertain, but records exist showing that the latter, recognising the value of these rich lands for corn growing, commenced a system of reclamation by making more direct channels for the flood waters, and embanking the lands.

This system of reclaiming the land of the delta has gone on persistently ever since. At first only the higher lands were embanked, but as population increased the aid of science was invoked, and mechanical agency was applied to the raising of the water from the shallower meres and lakes, the motive power being the wind. For four and a half centuries the fens and morasses, lakes and old river beds which had been converted into cultivated land were kept dry by the aid of innumerable windmills studded all over the country, some of the deeper polders requiring three engines, at different levels, to raise and discharge the water. About sixty years ago steam power was added to that of the wind, being first used for the drainage of Lake Harlem, by which 45,000 acres of rich land were recovered and a new province of 10,000 inhabitants added to the country. What was once a lake from 15 to 20 feet deep is now the great market garden of Amsterdam. "And so by the skill and genius of man there was thus driven from the bosom of the country a most dangerous enemy, and a province was conquered without tears and without bloodshed, the engineer taking the place of the general and the navvy that of the soldier."

Such is the physical history of the provinces of Holland known as the United Netherlands, which has a population of nearly five millions and covers an area of 12,738 square miles, of which about two-thirds consist of reclaimed lands, intersected by a system of main drains and navigable canals extending to a length of 2050 miles. The annual budget for the maintenance of these drains and banks amounts to 500,000*l*.

The land thus obtained has, however, only been held by one long-continued struggle between man and Nature; the ocean attempting to regain the land over which it had dominion, and the rivers striving to break through the barriers that have been imposed on them, the skill and perseverance of the Dutchmen being exercised in holding that which they had gained by the most careful guarding and watching.

For nearly twenty centuries the fight has been going on, from time to time the land being attacked both from the sea and land. At different periods the rivers, resenting the limits within which their waters have been restrained, have burst their bounds and flooded the country. This has generally happened after the breaking up of some great frost, when the water, flowing down in enormous volumes, has brought with it broken ice-drifts which, blocking in some bend or other obstruction, have stopped the progress of the flood. When this occurs the water finds relief by running over the top of the banks or breaking through them, covering thousands of acres and inundating villages and homesteads. Thus in the fifteenth century the Rhine burst its banks and flooded 100,000 acres and seventy villages. In another great flood nearly the whole of Holland was inundated and 400,000 lives were lost, the country being so depopulated owing to this vast loss of life that the damage done could not be made good, or the prosperity of the country restored, for many years.

Even more disastrous than the land floods have been the breaches made in the sand-hills and sea-dykes by abnormal high tides, due to gales lasting over several days, driving the water upon the shore. It was owing to one of these great storms, at the latter end of the thirteenth century, which lasted for several days, that the water of the North Sea was raised to an unprecedented height and driven by the north-west gale on the sandbanks which protected the north coast, breaking through these in several places and inundating an enormous tract of country lying behind. By this breach the province of Friesland was separated from that of North Holland, and the water, uniting with Lake Flevo, formed the Zuiderzee, a vast inland salt-water sea 80 miles long and in places 30 miles wide. Remains of the original coast-line exist in the islands of Texel, Vlieland, Tor Schelling and Ameland. In the Zee the higher parts of the inundated land are now marked by the islands of Wieringen, Schakland, Marken and Urk, the latter of which is so little above the level of the sea that the greater part of it is covered with water whenever extraordinarily high tides occur, the houses and church standing on mounds slightly elevated above the rest of the island. Numerous villages, with their churches and homesteads, which once contained a numerous population, now lie buried beneath the waters of the Zuiderzee, and it is stated that 80,000 of the inhabitants lost their lives.

For more than six centuries the area then drowned has remained an inland sea, on which a numerous fishing

population gains its living, the plough and the waggon having given place to the net and the boat.

The reclamation of Lake Harlem having demonstrated the great advantages to be gained by such works, several schemes were subsequently brought forward for reclaiming the Zuiderzee and regaining what was thus stolen by the sea, the most extensive of these plans proposing the joining together of the islands which were left standing, and filling the gaps between them by embankments.

At last, in 1894, a Commission of twenty-seven members was appointed by the Government to make a thorough investigation of the subject, the commissioners being selected for their special capabilities for determining as to the practicability of the reclamation from an engineering point of view, and as to the cost; as to the adaptability of the land for agricultural purposes, and its value when reclaimed; as to the proper way of dealing with the interests of the fishermen who would be displaced; and generally the advantages that would occur to the State. This Commission reported in 1892, and recently a Bill was brought before the Dutch States General for carrying into effect the recommendations of the commissioners. Owing to a change in the Ministry the Bill lapsed before it had passed through the necessary stages, but there is no doubt that it will be revived in due course by the new Ministry.

The idea of entirely reclaiming the whole of the Zuiderzee by uniting the islands has been abandoned as commercially impracticable, and a modified scheme adopted for only enclosing the inner portion by an embankment 18 miles in length, extending from the North Holland coast near the island of Wieringen to the Friesland coast near Piaam. The top of this embankment will require to be 18 feet above mean high water, and it is proposed to construct in it two locks and six outfall sluices, giving a total waterway of 984 feet for the discharge of the water from the River Ysell. One of the locks is to be of sufficient size for sea-going craft, which will thus be able to get to Amsterdam through the locks at Schellingwoude and to other parts of Holland along the various canals that now have communication with the Zuiderzee. On the top will run a road and railway. The estimated cost of this bank is 3,000,000*l.* When the bank is completed it is proposed to reclaim two large areas of land on the west side which are now covered by water, containing together 131,450 acres, of which 115,000 acres will be available for cultivation, the remainder being occupied by roads, drainage canals and banks. For the drainage of these reclaimed polders eight steam pumps will be required, of an aggregate capacity of 4330 horse-power.

Subsequently it is intended to reclaim two further tracts containing 365,288 acres, but this reclamation was not included in the Bill now under consideration. When this is done there will remain a large area of water, practically the site of Lake Flevo, covering 560 square miles. It is considered that the depth of the water in this lake is too great for profitable reclamation. The cost of enclosing the two tracts of land and providing the necessary pumping machinery is estimated at 2,962,500*l.* For the interests of the fishery 375,000*l.* is allocated; for military defences, 666,000*l.*; for deepening the approaches to the harbours and other works in the interests of the navigation, 717,000*l.*, making, with the cost of the bank, a total estimated cost of 7,720,500*l.* The enclosure of the eastern polders, containing 365,288 acres of cultivatable land, is estimated at 7,862,500*l.*, making a grand total of 15,583,000*l.*

The enclosing dyke is reckoned to occupy nine years; the reclamation of the western polders would be completed at the end of fourteen years, and it would take thirty-three years before the whole reclamation could be completed.

It is proposed that the cost of the works, amounting to 7,720,500*l.*, shall be repaid by annual instalments spread over sixty years, requiring an annual charge of 166,667*l.* The renting value of the reclaimed land is estimated at 230,000*l.* a year, showing an annual financial gain of 63,333*l.*

It is considered that, even if no financial gain should ensue, the scheme is one that will be of eminent advantage in the increase in the general prosperity:—by creating a better condition of the Waterstaat over a considerable portion of the country, and in effecting a large saving in the cost at present incurred in pumping; and in the maintenance of the sea banks, the length of which will be reduced from 198 to 25 miles; by the establishment of direct communication by road and railway along the new bank between North Holland and Friesland, which will shorten the distance between Leuwarden and Amsterdam 35 miles; and, above all, by the economic advantages that will be derived from the cultivation of a very extensive tract of land, and the employment that will be given to a very large population.

W. H. WHEELER.

SMALL-POX IN LONDON.

THE statistical committee of the Metropolitan Asylums Board has recently presented an interesting report upon the cases of small-pox which have been treated by the Board during the year 1901. This report enables us to trace the growth of the present epidemic, and, so far as it goes, dealing with 1017 cases of small-pox, teaches us some very useful lessons upon a subject at the present time of the most profound interest, viz., the efficacy of vaccination as a protective measure.

It appears that in the early part of last year, in fact up to August, London was unusually free from small-pox, only slightly more than a dozen cases having occurred. From August 22 and on, however, the disease appeared to have obtained a strong hold in the parishes of St. Marylebone and St. Pancras. Subsequently cases occurred in every one of the thirty-one poor-law parishes and unions comprising the Metropolitan Asylum District. The average weekly admissions were as follows:—In August, 35·5, September, 37·75; October, 39·75; November, 113·6; December 1 to 28, 164·5; December 28 to January 4, 242·0.

With regard to gross mortality, this is given at 24·28 per cent. It must, however, be borne in mind that in arriving at this figure many cases of recent admissions have been included because they have already been completed by death, whereas the contemporary cases, which will probably nearly all recover ultimately, cannot be included until completed by discharge. The result is that the rate of mortality above must be admitted to be undoubtedly higher than it will be when all the cases have been completed and the final rate ascertained.

For the purpose of estimating the effect of vaccination upon the cases which have died or recovered during the year, these were divided into three classes: (1) cases with visible cicatrices, (2) doubtful cases, (3) unvaccinated cases. The total mortality rate per cent. of vaccinated cases was 14·21; of doubtful cases 65·08; of unvaccinated cases 50·52. It strikes one at first as odd that the mortality of the doubtful cases was ten per cent. higher than that of the admittedly unvaccinated. By definition it, however, appears that the doubtful cases most probably consisted of practically unvaccinated cases, and were very few in number. Perhaps one of the most marked features in these statistics is the protection from small-pox afforded by successful infantile vaccination. Under ten years of age only twelve vaccinated cases are recorded and no death. Infantile vaccination, further, seemed greatly to diminish the rate of mortality from the disease even up to forty, although there was a very rapid

falling off of its power in this direction after twenty years of age.

With regard to the value of and necessity for re-vaccination, the experience of the committee confirms that of a similar committee which reported upon the small-pox epidemic of 1870-72. "No greater argument to prove the efficacy of this precaution," says this report, "can be adduced than the fact that out of upwards of 14,000 cases received into the hospitals only four well-authenticated ones were treated, in which revaccination had been properly performed, and these were slight attacks."

NOTES.

THE work of preparing Bushy House for the National Physical Laboratory is now approaching completion, and, His Royal Highness the Prince of Wales has fixed Wednesday, March 19, for the opening ceremony. The object of the Laboratory is to encourage the applications of physical science to manufactures and industry. This it will do by undertaking researches into questions of importance to either, and by testing apparatus and material used in trade.

PROF. J. W. GREGORY, F.R.S., has been temporarily appointed head of the Geological Survey of Victoria, with a view to its complete reorganisation and the substitution of a staff engaged on a permanent basis instead of the present temporary plan. The Victorian Government is paying for extra assistance in the geological department of the University while Prof. Gregory is engaged upon this work.

AN expedition to Lake Eyre, the great depression in Central Australia sinking below sea-level, has recently left Melbourne. The party consists of Prof. J. W. Gregory, his assistant, Mr. H. J. Grayson, and five students of the geological department of the Melbourne University. The main objects of the expedition are the study of the physical history of the Lake Eyre basin and the collection of fossils, especially the extinct giant vertebrates. The camel caravan starts from Hergott Springs, a station 440 miles north of Adelaide. It is hoped that the collections will throw light on some unexplained native traditions as to former giant animals that inhabited the Lake Eyre basin.

THE annual congress of the Sanitary Institute will be held in Manchester on September 9–13, when Earl Egerton of Tatton will preside. Section I. (Sanitary Science and Preventive Medicine) will be presided over by Sir J. Crichton Browne, F.R.S.; Section II. (Engineering and Architecture) by Sir Alexander Binnie; and Section III. (Physics, Chemistry and Biology) by Prof. A. Sheridan Delpéine. Eight technical conferences will also be held in connection with the congress.

IN the House of Commons on Monday, in reply to Mr. Field, who asked a question in regard to the proposed erection of a suitable College of Science in Dublin, Mr. Austen Chamberlain said:—"Thirteen thousand pounds was voted in 1899–1900 and applied towards the purchase of part of the site for a new college. I hope shortly to introduce a Bill for the acquisition of the rest of the site, for the provision of funds for the new building, and other purposes. I have satisfied myself by personal inspection of the existing college that that building is quite inadequate to the work which it is intended to perform."

THE American Society of Naturalists held a successful meeting at Chicago at the commencement of this month. There was a discussion on the relation of the Society to other scientific societies, an address by the president, Prof. Sedgwick, on the modern subjection of science and education to propaganda, dealing largely with attempts to prevent the experimental study of physiology, a lecture by Dr. Howard on international work with beneficial insects, and 244 papers on scientific subjects. The society will meet next winter at Washington, in conjunction with the American Association for the Advancement of Science. A committee was appointed to confer with a similar committee to be appointed by the naturalists of the central and western States in regard to the relations of the two societies. At the meeting to be held next year the president will be Prof. J. McKeen Cattell, and the vice-presidents Messrs. C. D. Wolcott, L. O. Howard and D. P. Penhallow.

WE learn from *Science* that Mr. Andrew Carnegie's gift of ten million dollars for scientific research has been transferred to a corporation to be known as "The Carnegie Institution." The original incorporators include Dr. D. C. Gilman, lately president of Johns Hopkins University, the Hon. Chas. D. Walcott, Director of the U.S. Geological Survey, Dr. John S. Billings, and the Hon. Edward D. White. The objects of the Institution, in addition to the promotion of research, are set forth as follows:—To acquire, hold and convey real estate and other property necessary for the purpose of the Institution and to establish general and specific funds. To conduct, endow and assist investigation in any department of scientific literature or art, and to this end to cooperate with Governments, universities, colleges, technical schools, learned societies and individuals. To appoint committees of experts to direct special lines of research. To publish and distribute documents, to conduct lectures and to hold meetings. To acquire and maintain a library and, in general, to do and perform all things necessary to promote the objects of the Institution.

ON January 17 Lord Rayleigh opened this season's Friday evening meetings at the Royal Institution with a discourse on the interference of sound. In the course of his remarks he described some of his recent experiments with fog-horns, made for Trinity House. Fog-horns with elliptic cones instead of circular ones were tried, the major axis being about four times longer than the minor one. The experiments showed that the sound was best spread in a horizontal direction when the long axis was exactly vertical. It appears to be doubtful whether the phenomenon of the silent area is really due to interference between waves of sound reaching the spot direct and those reflected from the sea. If the effect were merely due to interference in this way, it ought to be possible to recover the sound by the listener changing his altitude above the sea surface, but Lord Rayleigh has on several occasions tried this on board the *Irene* and has not recovered the sound. When two or more fog-horns are used at one station, it sometimes happens that owing to the different sound waves being out of phase they more or less neutralise one another at certain distances, so that one source of sound is sometimes better than several. At the close of Lord Rayleigh's discourse, the Duke of Northumberland, as president of the Institution, unveiled a bust of Sir Frederick Bramwell, formerly honorary secretary of the Institution, and formally presented it to the members on behalf of the managers and their friends as a token of esteem.

THE death is announced of Prof. H. von Ziemssen, professor of pathology and therapeutics in the University of Munich.

COMMISSARY-GENERAL G. D. LARDNER, whose death at the age of eighty-four we regret to see announced, was the eldest son of the renowned Dr. Dionysius Lardner, and, like his father, he did much to encourage the study of astronomy, though his writings and lessons did not reach so large a public. He was a Fellow of the Royal Astronomical Society, and devoted his

leisure hours to scientific pursuits and to inspiring interest in natural knowledge in others. The death of such a man is a real loss to science.

ANNOUNCEMENT has already been made of the death, on December 24, 1901, of Mr. Clarence King, who for a short time was Director of the Geological Survey of the United States. His most important work was in connection with the geological exploration of the fortieth parallel, of which the main portion, published during the years 1876 and 1877, comprised various reports and the geological and topographical atlas of the Rocky Mountains, the Green River and Utah Basins, and the Nevada Plateau and Basin. At this date there were two other important geological surveys in the States apart from various local surveys; thus G. M. Wheeler was directing the surveys west of the 100th meridian, and F. V. Hayden was in charge of the Survey of the Territories. The three main surveys were consolidated in 1880 as the United States Geological Survey, under the directorship of Mr. King. Coming to the work from a long and successful experience, he elaborated a comprehensive plan of operations, and vigorously prosecuted the same through the assistance of a wisely selected corps of geologists and specialists. He directed investigations on Leadville in Colorado, on the Eureka district, and on the Comstock lode in Nevada. Mr. King, however, held office for a year only, retiring in 1881, as he believed he could render more important service to science as an independent investigator. He was succeeded by Major J. W. Powell, from whose introductory remarks in the second annual report of the United States Geological Survey we gather some of the above particulars. The hope entertained by Mr. King was not fulfilled, as unquestionably his most valuable contributions to science were his official maps and reports. In later years his most important paper was that on the age of the earth, which appeared in the annual report of the Smithsonian Institution for 1893.

SOME of the scientific results obtained by members of the National Antarctic Expedition during the voyage of the *Discovery* from the Cape to New Zealand are mentioned in an article in last Saturday's *Times*. It was part of the instructions of the expedition that the *Discovery* should proceed southwards towards the point of maximum total magnetic force. The despatches received state that on November 12, 1901, in latitude 50° S., longitude 131° E., Captain Scott determined to turn southwards towards this focus, running more or less on the line of no variation. The result was a very gradual increase of total force, while there were other points of interest in the observations of the dip and variation. The *Discovery* continued to push southwards till November 16, when the first ice was sighted. The detached pieces which were first met with were soon succeeded by a loose pack of drift ice, with occasional fragments of glaciers. On November 16 a sounding was taken in 2300 fathoms, while the magnetic observations showed a dip of 86°. The furthest south point reached was 62° 50′, in longitude 139° 40′ E. The highest glacier was seen on November 17, when another sounding was made in 2300 fathoms. The *Discovery* turned north-eastwards on November 17, and on the 18th a sounding was made in 1750 fathoms. Captain Scott then made as rapidly as possible for his destination in New Zealand. On November 22 Macquarie Island was reached. A landing was effected, and the naturalists did some good work. Auckland Island was sighted on November 25, and Lyttelton was reached on November 28. As already announced, the *Discovery* has since then turned her face southwards to enter upon the real work of the expedition. In order that the expedition may be in a position to complete the work for which it has been organised, it is essential that it should be free to remain away for at least two, and if possible three, years, as is the case with the cooperating German expedition. For this end more funds are absolutely necessary (1) to supplement the equipment of the main expedition, and (2) to send out a second ship in the autumn of 1902. The second ship is indispensable if the expedition is not to return after one year's work. It is required to take out a further supply of coal and other stores, to bring away any members of the expedition who may be incapacitated, and to leave suitable substitutes, as well as to obtain information as to the further plans of the expedition. About 6000*l.* has been subscribed for this purpose, and at least 10,000*l.* more is required in order to equip and man the ship which has been obtained. The urgency of the need should inspire those who have the means to come forward with liberal offers of assistance.

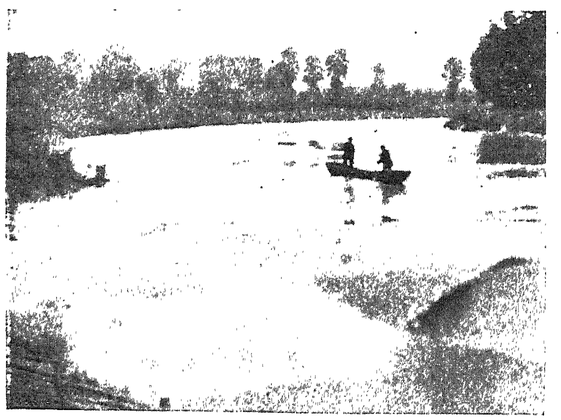
A PAPER on modern machine methods, by Mr. H. F. L. Orcutt, read at the Institution of Mechanical Engineers on Friday last, contains a large amount of information in illustration of the value of perfected methods of machining. The use of accurate limit gauges instead of measuring with micrometers or calipers is strongly urged, even in small shops. There is a widely spread and erroneous idea, particularly amongst European manufacturers who would emulate American manufacturers, that the latest methods cannot be economically adopted except where work is thoroughly standardised, specialised, and made in large quantities. Mr. Orcutt thinks otherwise, and remarks that a single hole is more cheaply bored in a chucking machine than in a lathe. It is more easily made to a limit gauge than when the skill of a workman in setting his calipers has to be trusted. One spindle is more cheaply finished in the grinding machine than in the lathe, quality duly considered, and, again, is more easily finished to a limit gauge than to calipers, with the employment of less skilful labour. The idea that big quantities and standard work are necessary before modern equipment begins to play an important part in the economics of manufacturing, is described as the delusion of those who have grasped but a small part of the problem. The advantages of possessing a well-equipped laboratory and testing department are pointed out. Materials should be studied with a view to selecting that which is most suitable for the purpose, which, being most suitable, can be most rapidly machined, and which, fulfilling all conditions, is the cheapest. This cannot be accomplished with the haphazard methods commonly employed. Where the size of a shop does not warrant the expenditure necessary to support its own department, several manufacturers ought to combine and contribute to the support of a fully equipped laboratory. There is, however, Mr. Orcutt states, no practical reason why every mechanical engineering establishment in the United Kingdom should not have a testing institution at its command which could be constantly in use. The realisation of this state of affairs would be of incalculable benefit to the industries and commerce of Great Britain.

THE report of the proceedings of the fifth Congress on Criminal Anthropology has just been issued. Prof. G. A. van Hamel, the president, briefly described, in his opening speech, the scope of anthropology so far as it is concerned with criminology. Prof. Lombroso gave the Congress a comprehensive sketch of the progress of anthropological research since 1897, and read a paper on the prevention and treatment of crime. He was of opinion that the passions which inspire many serious crimes, especially those committed from political motives, were energies which might be turned to the advantage of the community if only they were classified and directed into the proper channels. Profs. Lacassagnes and Martin, adopting as their text *les sociétés ont les criminels qu'elles méritent*, contended that the only way to stamp out *recidivistes* and habitual criminals was to enact drastic laws to limit the consumption of alcohol,

and to provide against the dissemination of tuberculosis and venereal disease. Dr. Garnier, of Paris, stated that juvenile crime, which was rapidly increasing, was the result of the prevalence of alcoholism. Mr. Alexander Sutherland, of Melbourne, suggested that too much importance ought not to be attached to the theory of heredity, so far as it applied to crime, and pointed out that while in 1850 the population of Australia was composed of 135,000 individuals who were either convicts, or the children of convicts, and of only 105,000 normal persons, in 1880, after the course of but one generation, the number of criminals in Australia per 10,000 of the population was much below that in Prussia, Saxony, Italy and Sweden.

IN the *Scientific American* for January 4, Mr. L. P. Gratacap gives a popular and illustrated description of the discovery and preservation of the remains of the great dinosaur, brontosaurus, which have recently been placed in the Natural History Museum, New York. It was in 1898, under the direction of Prof. Osborn, that the colossal vertebræ, ribs and pelvic bone of the dinosaur were obtained from the Jurassic limestones of Wyoming. The total length of the animal has been estimated at more than sixty feet. The bones were taken out *en bloc* in the field, retained in the enveloping matrix, and shipped to New York, where a corps of skilled workmen finally extracted them from the stony matrix in the most perfect condition.

THE accompanying illustration of the Severn Bore is reproduced from a portion of the kinematograph picture recently obtained under Dr. Vaughan Cornish's direction with a bio-



scope camera and exhibited at the Royal Geographical Society. When first projected on the screen the Severn is seen at low water; in a few seconds the bore appears round the bend of the river about 500 yards distant, and it takes rather more than one minute to arrive at the position shown in the illustration. It is only upon reaching the shoal water near the camera that the wave curls over as here shown. The dark-fronted wave then rushes out of the field of view and the remainder of the film records the rapid current which follows close upon the bore. The film is 150 feet long with 2400 pictures, about half of which are views of the bore itself. The moving picture not only enables those who have never seen a tidal bore to realise the phenomenon with a completeness impossible from the examination of stationary photographs, but it provides a means for exhibiting at will a phenomenon which in nature is never precisely repeated. By repeating the projection of the picture as often as required, the various aspects of the phenomenon can be successively studied in a manner impossible to the observer of the bore itself. How much escapes observation when watching a transitory phenomenon, and the advantage of repeated projection on a screen, may be gathered from the various accounts which different spectators give of a kinematograph picture which all have seen simultaneously, but in which the points of attraction and interest are different in the case of different individuals.

SIR CHARLES TODD, K.C.M.G., F.R.S., has recently issued his comprehensive volume of meteorological observations in South Australia, for 1898. The work is divided into three parts; sections 1 and 2 deal with the observations at Adelaide and a number of other stations, and contain a valuable discussion on the exposure of thermometers in different screens. Section 3 gives the monthly and yearly totals of rainfall at 432 stations, and comparisons of the results with the averages for previous years. The annual distribution of rainfall is also clearly shown on a tinted map.

MR. J. E. CLARK has contributed an interesting paper to *Symons's Meteorological Magazine* for this month, entitled "Day Darkness in the City." He has recorded the number of quarter hours at which artificial light was necessary between 9h. a.m. and 5h. p.m. (Saturday afternoons and Sundays excepted) at the Wool Exchange, between October and March, 1897–1901. The tables show that November, December and January are preeminently the dark months, although, on the mean, November is a good deal behind the other two. The only really bad foggy months in the four years were December 1899 and January 1901, with which may be compared the prevalent fogs of November and December last. A diagram showing the distribution of dark quarter hours during the day shows a rapid rise between 9h. and 10h. and again about noon. The author points out that these anomalies are associated with the lighting of office fires and with preparations in the restaurants; in fact, smoke plays a main part in the darkness during both high and low fogs.

IN the *Bibliotheca mathematica* (iii. 2) for December 30, 1901, Prof. Gino Loria, of Genoa, gives an account of the late Prof. Beltrami, with a fairly detailed statement of the mathematical theorems and formulæ discovered by him. The paper is illustrated by a portrait of Beltrami.

SOME observations on the variation of position of the apparent horizon relative to the true horizon on the lake of Geneva are described by Prof. F. A. Forel, of Morges, in the *Comptes rendus de la Société helvétique* for the Neuchatel meeting of 1899, recently received. The extreme relative displacements of the horizons, due to refraction, during eight months' observation varied from $-272''$ to $+501''$, the telescope being 2·5 metres above the lake. A table is given of corrections for refraction in terms of the difference of temperature at the surface of the lake and at the altitude of observation.

A SHORT paper on the observatory of the University of Durham is given by Prof. R. A. Sampson in the *Proceedings* of the Durham Philosophical Society. The observatory was built in 1840, and the chief event in its annals was the tenure of the post of observer by Richard Carrington, which, however, he resigned in 1852, after holding it for three years. From that time on the observatory seems to have had a chequered career until 1891, when the old equatorial was replaced by a new one. In 1896 a new departure was made; instead of the transit circle being renewed an almucantar was provided, and with this it is hoped to do rather better work than could be expected with a meridian instrument.

WE are glad to learn that the gliding experiments with which Lilienthal and Pilcher sought to investigate the balance and stability of machines supported by aëroplanes and aërocurves have not been discontinued since the death of these two investigators. A great deal of valuable work has already been done in America by Mr. Octave Chanute, and in conjunction with him

by Mr. Herring, both of whom have attained results in advance of those previously achieved, by the use of machines provided with movable wings. Still more recently, *i.e.* from October 1900 onwards, two other workers have attacked the problem, namely, Mr. Wilbur Wright and Mr. Orville Wright, of Dayton, Ohio. Mr. Wilbur Wright adopts a two-surfaced machine and assumes a horizontal position when gliding, with the view of diminishing head resistance. He has successfully worked with a surface area of double that used by previous experimenters, and has on several occasions extricated himself from the dangerous position in which Lilienthal and other observers have found themselves when suddenly brought to rest in a high wind.

PROF. V. MONTI has forwarded us three papers dealing with the question of prevention of hailstorms, which is now exciting so much interest in Italy. One of these, published by the Italian Meteorological Office, deals generally with the distribution of hailstorms in Italy at different seasons. Prof. Monti divides Italy roughly into three different regions, the "Padan" region, including the valley of the Po and certain Alpine stations, where hailstorms commence between the end of February and May and cease about November; the "Peninsular" region, where no month is altogether exempt from hail; and the "Calabro-Sicilian" region, which is characterised by an almost complete absence of hailstorms during the summer months. A second paper deals with the question of whether hailstorms are affected by the detonations accompanying volcanic eruptions. In it Prof. Monti discusses an account of a hailstorm on Stromboli, by M. Brun, of Geneva, and other writers, and he infers that (1) the fall of hail is not prevented by volcanic detonations; (2) hail may even be formed in storms of volcanic origin, contrary to Faye's theory. In the third paper Prof. Monti discusses the effect of thunder on the production of hail, and quotes letters on the subject. He finds that two-thirds of the heavy hailstorms that have been carefully studied are accompanied with loud thunder ("tuoni forti o fortissimi"), and that the frequency of the thunder, both before and during the hail, does not prevent the formation of large hailstones. In one storm at Campofreddo, near Genoa, where the hail was large and abundant, the thunder was so violent as to break windows. The theory according to which hail is dispersed by cannonades, as the result of the atmospheric waves produced, derives no support from the observed results in connection with either volcanic explosions or thunder.

THE latest issue of the *Zeitschrift für wissenschaftliche Zoologie* (vol. lxx. part iv.) contains four papers, as usual, of a highly technical nature. The first, by Dr. E. Botezat, treats of the terminations of nerves in the taste-corpuscles. In the second, Herr P. Morgenstern describes the development of the hydroid zoophyte *Cordylophora lacustris*. Certain reproductive organs of sharks form the subject of a long article by Herr O. Huber; while Dr. E. Ballowitz treats of the gastrulation of the ovum of the common grass-snake. All the articles are illustrated by plates.

IN a pamphlet published at Frankfurt-am-Maine and bearing the title "Der Zoologische Garten des Museu Goeldi in Pará (Brasilien)," Dr. G. Hagmann, an assistant on the staff, gives an excellent and well-illustrated account of the rise and progress of the menagerie which has been formed under the direction of Dr. E. Goeldi, the able chief of the museum. It was in 1893 that Dr. Goeldi, then attached to the museum at Rio, was appointed to take charge of and reorganise the museum at Para; but, owing to the military revolution which then disorganised the greater part of Brazil, it was not till late in the following year that he was able to assume the duties of his new post. It was not long before his attention was directed to the formation of a zoological garden to illustrate the local fauna, and by 1895 this was in full working order. In the present pamphlet we have a list of the vertebrates—all natives of Brazil—which have been exhibited in the garden between July, 1895, and July, 1901. These comprise sixty-five species or races of mammals, one hundred and twenty-seven of birds, thirty-five of reptiles and amphibians, and nine of fishes. Many of the species exhibited are very rare, and much new information has been acquired in regard to the habits of several. Judging from the photographs with which the pamphlet is illustrated, the appearance of the garden must be highly attractive, and the idea of devoting it entirely to the local fauna is most excellent.

NOTICING that the tang of the head of some Eskimo arrows are provided with a screw, Herr Krause asks whether the screw is an Eskimo invention (*Globus*, lxxix. 1901, p. 8), for it would be strange if a people still in their stone age had in a mechanical contrivance progressed beyond highly cultured, superfine Romans of the Empire. Dr. Karl von den Steinen (*Globus*, lxxix. p. 125) answers this question in the negative, and points to the considerable trade there has been between the natives and numerous European sailors during the last century, and any extensive collection of Eskimo objects will also demonstrate that borrowing has taken place. Mr. H. Newell Wardle replies to Dr. von den Steinen (*Globus*, lxxx. 1901, p. 226) and points out that the Eskimo sometimes made their harpoon heads of the tooth of the narwhal, and as this has a spiral twist there is no need to seek elsewhere for a screw; he therefore thinks it will probably always remain an open question. The relation of the sickle to the saw, on the one hand, and to the dagger on the other is the subject of a learned philological and ethnographical treatise by Herr Hugo Schuchardt in *Globus* (lxxx. pp. 181 and 204).

A SECOND edition of the second volume of Prof. J. R. Green's "Manual of Botany" has been published by Messrs. J. and A. Churchill. The volume is concerned with plant classification and physiology, and several additions have been made with the view of increasing its usefulness and rendering it more readable. Prof. Green provides students with a valuable course of training in systematic botany and plant physiology.

WE have received the following botanical reprints from the United States, the first three being from the *Botanical Gazette*:—"A Study of the Sporangia and Gametophytes of *Selaginella apus* and *S. rupestris*," by Florence M. Lyon, a very careful study, illustrated by five plates; "Development of the Pollen in the Asclepiadaceæ," by T. C. Frye, from which it would appear that the connection of the pollen-grains into pollinia in this order is not associated with any speciality in the mode of development of the sporange; "Further Notes on the Physiology of Polymorphism in Green Algæ," by B. E. Livingston, relating chiefly to the effect on Algæ of cultivation in various nutrient solutions; "The Seed-coats of certain Species of the Genus Brassica," by A. J. Pieters and Vera K. Charles, being *Bulletin* No. 29 of the U.S. Department of Agriculture, Division of Botany; "The Progress made in Botany during the Nineteenth Century," by Wm. Trelease, from the *Transactions* of the Academy of Sciences of St. Louis.

THE fact that the atomic weights of some of the most important elements have not as yet been determined with a sufficient degree of precision is clearly illustrated by a new determination of the atomic weight of calcium by F. W. Hinrichsen, the results of which are published in the last number of the *Zeitschrift für physikalische Chemie*. In spite of the importance of this element and numerous investigations carried out to determine its atomic weight, the latter cannot be said to be known with certainty. The value generally accepted as being most trustworthy is the result of a determination by Erdmann and Marchand in 1850, in which they obtained $Ca = 40{\cdot}00$.

This is the number given on the tables of atomic weight issued by the German Chemical Society. Hinrichsen's method consists in the conversion of extremely pure Iceland spar into oxide of calcium. The only measurable impurity present in the spar was iron, the amount of which expressed as ferric oxide was ·032 per cent. The conversion into oxide was effected in specially constructed platinum crucibles, the latter being heated in an electric oven at a temperature of 1200–1400° C. Four determinations of the atomic weight gave respectively 40·144, 40·141, 40·142 and 40·141—mean =40·142. This number deviates considerably from that which up to the present time has been generally accepted.

IN a paper on the fossil shells of the Colorado desert, published in a recent issue (No. 1256) of the *Proceedings* of the U.S. Museum, Dr. R. E. C. Stearns gives an interesting account of the formation of the desert itself. Surrounded by mountains except in the south, where it opens out, the Colorado desert of California was evidently once an extension of the Californian Gulf, which must once have reached inland some two hundred miles further than at present. The separation of the upper end of this old gulf, now forming the desert, has been caused by the sediment brought down on the east side by the Colorado river, which gradually silted up this portion of the gulf till the present desert area was isolated. Throughout the desert are to be found thousands of small fresh-water subfossil shells, mostly referable to the genera Paludestrina and Physa, which appear to have been transported partly by whirlwinds, but chiefly by birds. Some of the species of these molluscs are still living in certain localities in the desert. The remarkable variation exhibited by the shells of certain species is described in detail.

THE additions to the Zoological Society's Gardens during the past week include a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mr. F. S. Davidson; a Verreaux's Guinea-fowl (*Guttera edouardi*), a West African Python (*Python sebae*, var. *natalensis*) from Natal, presented by Mr. W. Champion; a Hudson Bay Squirrel (*Sciurus hudsonius*) from the Rocky Mountains, presented by Mr. Edward Whymper; a Lesser Sulphur-crested Cockatoo (*Cacatua sulphurea*) from Moluccas, deposited.

OUR ASTRONOMICAL COLUMN.

DIMENSIONS OF THE PLANETS AND SATELLITES.—In the *Astronomische Nachrichten* (Bd. 157, No. 3760), Prof. E. E. Barnard presents a series of revised reductions of measures made at the Lick Observatory in 1894 and 1895, together with recent determinations with the 40-inch refractor at the Yerkes Observatory.

Mercury.—The measures of diameter were made in the daytime, when the disc of the planet was little brighter than the sky background. Powers of 230, 460 and 700 diameters were used, and a piece of amber-coloured glass was placed as a screen over the eye-piece. The resulting mean value of the diameter was 2965 miles. During the observations the disc of the planet was carefully examined for the linear canal system described by other workers, but no such markings were seen. Under excellent conditions (especially on August 31, 1900), however, decided details in the form of three or four large darkish spots were readily distinguished, and were comparable to the markings on the moon as seen with the unaided eye.

Venus.—Measures were made of this planet specially to determine the extent of variation due to irradiation; night and day measures were both made with the full aperture of 40 inches, but the amber screen was used for the day series. The value obtained for the irradiation was 0″·25. The day diameter of the planet is given as 7713 miles. A series of dusky markings were the only features observed on the disc, similar to but fainter than those on Mercury.

Minor Planets.—Measures of the albedos and diameters of the four chief asteroids were obtained, with the following results:—

	Albedo. Mars = 1.	Diameter.
Ceres	0·67	477 miles.
Pallas	0·88	304 ,,
Juno	1·67	120 ,,
Vesta	2·77	239 ,,

As seen in the 36-inch and 40-inch telescopes the discs of such asteroids as are measurable always appear well defined and round, with no traces of markings on their surfaces. The corrected values for the other planets are as under:—

	Diameter.
Mars (Equatorial)	4352 miles.
,, (Polar)	4312 ,,
Jupiter (Equatorial)	90,190 ,,
,, (Polar)	84,570 ,,
,, Satellite I.	2452 ,,
,, ,, II.	2045 ,,
,, ,, III.	3558 ,,
,, ,, IV.	3345 ,,
Saturn (Equatorial)	76,470 ,,
,, (Polar)	69,780 ,,
,, Satellite Titan	2720 ,,
Uranus (Equatorial)	35,820 ,,
,, (Polar)	33,921 ,,
Neptune	32,900 ,,

No markings were observed on Neptune, and its disc always appeared round.

HARVARD COLLEGE OBSERVATORY REPORT, 1901.—In his report for the year ending September 30, 1901, Prof. E. C. Pickering first mentions that of the three important astronomical events of the year, the Harvard College Observatory staff only participated in the determination of the light variation of Eros and the complete investigation of the changes of Nova Persei. The reason why no measures of Eros for parallax were made was that some fifty other institutions were cooperating in the work, rendering observations at Harvard unnecessary; in the case of the total eclipse in Sumatra the conditions were not considered sufficiently favourable to justify any large expenditure.

East Equatorial.—This instrument has been employed, as in former years, for photometric light comparisons with the achromatic prism polarising photometer; more than 16,000 settings have been made, including 1224 measures of the magnitude of Nova Persei. For double stars, &c., too close for examination with the above instrument, a second photometer has been adapted, and 2278 settings made with it. Other work with this equatorial has been the photometric measurement of Jupiter's satellites while undergoing eclipse, the light variations of the minor planet Eros and the asteroids Vesta and Tercidina, comparisons of long-period variables, and the selection and measurement of twelfth-magnitude standards.

West Equatorial.—This has been employed for similar photometric work on variables and comparison stars.

Meridian Circle.—Work with this instrument has chiefly consisted of zone observations to compare results obtained by use of crossed spider threads or ruled glass plates. The conclusions have been published in *Annals*, vol. xli. No. 7.

12-inch Meridian Photometer.—With this instrument 54,448 settings have been made by the director on 126 nights. A catalogue of 9233 Durchmusterung stars has been completed, and the planet Eros observed on 56 nights.

Meridian Photometer.—33,316 settings have been made on 98 nights, the principal work being the observation of a catalogue of 376 standard stars of the fifth magnitude; also comparison stars for Eros and other similar objects.

Henry Draper Memorial.—With the 11-inch Draper telescope 673 photographs have been obtained, and with the 8-inch instrument 1766 photographs. The total number of photographs taken during the year was 4081. Two new variables, three stars with peculiar spectra, and the presence of bright hydrogen lines in the spectrum of U Andromedæ, have been detected. Photographs of the spectrum of lightning were obtained with the Draper telescope with objective prism during the summer.

Respecting the production of stellar spectra two new devices are announced. For photographing the spectra of stars near the horizon, below 10° altitude, the plan has been adopted of turning the objective prism by a computed amount so as to correct for the atmospheric refraction in declination. The stellar

spectra have been shaded automatically during the process of reproduction so as to equalise the intensity throughout.

As systematic work the 8-inch telescope covers all parts of the sky north of declination $-12^{\circ}\cdot5$ from two to four times a year; the Cooke lens covers all parts available two or more times a month, and the transit photometer records all stars visible to the naked eye crossing the meridian every clear night.

Arequipa Station.—The 13-inch Boyden telescope has been used for photographing clusters containing probable variable stars. With this instrument 140 plates have been obtained; 2269 with the 8-inch Bache telescope and 919 with the 24-inch Bruce lens. From the examination of these latter plates 298 new nebulæ have been found, of which 9 are spiral and 3 ring nebulæ.

The long focus telescope is now back from Jamaica, where a long series of photographs of the lunar surface has been obtained under five different illuminations. These will furnish material for a photographic atlas. The diameter of the moon's image is about fifteen inches.

Blue Hill Meteorological Station.—Continued experiments are being made in the exploration of the upper atmosphere by means of kites, altitudes up to 12,550 feet having been obtained. Considerable success has attended the endeavour to fly the kites from ocean-going vessels in order to record weather conditions away from land surfaces.

TOTAL ECLIPSE OF THE SUN, MAY 18, 1901.—In *Popular Astronomy* (vol. x. pp. 1–4, January), Prof. A. N. Skinner gives an account of the expedition to Sumatra from the United States Naval Observatory. Three stations were selected, at two of which the weather conditions were unfavourable. At the third, Fort de Koch, excellent photographs of the corona and the chromospheric spectrum were obtained. The former were taken with a lens of 5 inches aperture and 39 feet focal length; two of these are reproduced with the article; the spectroscopic equipment consisted of a 30-feet concave grating spectrograph, with which six photographs were obtained.

A MAGAZINE OF SCIENCE AND PHILOSOPHY.[1]

"ANOTHER new magazine!" But the editor, in anticipating this exclamation, suggests that it is no more reasonable than would be "Another new flower in the fields!" or "Another new tree in the wood!" Still, one is not obliged to pluck the flower or to cut down the tree; but a new magazine makes a certain claim on the attention of the public, especially as it is addressed to the scientific public as well as to philosophers in the stricter sense of the word. Indeed, it is an attempt to induce men of science to interest themselves more in philosophy and students of philosophy to pay more attention to modern science. It is not intended to serve as a means of popularising either of these regions of thought, and the editor promises to exclude all purely speculative matter for which an experimental basis is wanting.

The first number contains an interesting article by Mach on "Similarity and Analogy as an aid to Investigation," in which Huygens, Faraday, Maxwell and Kelvin are held up as examples of investigators who have made sound use of analogy and have contributed, in consequence, greatly to the progress of human knowledge. Wald contributes "Critical Studies on the most important Fundamental Conceptions of Chemistry." It must be confessed that this introduction (for more is promised hereafter) is not very intelligible. "The Principle of Continuity in the Mathematical Treatment of Natural Phenomena" is the title of an article by Anton Scheye. The first chapter considers the principle as illustrated in the calculus; the second deals with the principle of continuity in natural science; the third, in mechanics; the fourth, in electrical and thermal phenomena; in the fifth the kinetic theory of gases is discussed; and the sixth chapter treats of the hypothesis of matter and of energetics. Here objections are raised to Ostwald's conclusion that "Our senses tell us of differences in energy between them and their surroundings"; for it is remarked that if equal quantities of energy be imparted to two bodies of equal mass yet of different specific heat, having the same initial temperature, while the final temperature of each will be the same, heat will have passed from the one of lower to the one of higher specific heat; and yet each will affect the sense of temperature equally, though they have gained different amounts of energy. He insists, therefore, that besides energy there must exist some other magnitude which must not only be capable of mathematical treatment, but must be as necessary for the true description of occurrences as energy itself. He also questions whether the doctrine of energy suffices to describe such a stationary condition as two equal light-rays polarised at right-angles to each other, or to picture the stationary state which exists when energy flows in a field of permanent magnets and charged conductors, according to Poynting's law. For these and other reasons he regards it as probable that an interpretation of the universe will be more complicated than would be the case were Ostwald's energetic conception possible.

Ostwald contributes a critical article on Kant's "Metaphysical Basis of Science." To Kant's statement that true science must treat its subject-matter according to *a priori* principles, and that only science falsely so-called deals with laws deduced from experiment, Ostwald replies by denying the possibility of *a priori* conclusions, and maintains that all knowledge is derived from experience. Another celebrated dictum of Kant's is that in any investigation of Nature only so much real science is present as is expressible in mathematical terms; Ostwald insists, however, that mathematics is only a language in which the results of experiments may be conveniently expressed, and that it can contain nothing more in its conclusions than what experiment lends to its premisses. And while Kant, although acknowledging that in principle his scientific treatise has a close connection with the ordinary province of metaphysics, to wit, God, Freedom and Immortality, distinguished them sharply, regarding the former "as a shoot from the same root as the latter, but one which hinders its regular growth," Ostwald maintains that no stronger argument can be found for the necessity of a purely experimental basis for all branches of knowledge.

A somewhat technical article by Arthur von Oettingen on "The Dual System of Harmony," and one by E. Sievers on "Melody of Voice in (Reciting) German Poetry," are followed by reviews of new books by the editor. Among these it is somewhat amusing to find Judge Stallo's "Concepts of Physics," which has only now reached the German public, through its translator, H. Kleinpeter. W. R.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. T. H. Middleton, professor of agriculture in the Durham College of Science, Newcastle-on-Tyne, has been elected to the chair recently vacated by Dr. Somerville.

Dr. Barclay-Smith has been reappointed senior demonstrator of anatomy.

The Vice-Chancellor, Prof. J. J. Thomson, and Mr. R. T. Wright will represent the University at the jubilee of Owens College, Manchester, to be celebrated next March.

EDUCATION was given first place in the King's speech to the Commons at the opening of Parliament last Thursday. The words used were "Proposals for the Co-ordination and improvement of Primary and Secondary Education will be laid before you." It is to be hoped that a comprehensive measure will be introduced early in the session, and that nothing will be permitted to interfere with the settlement of the questions involved in it.

THE adoption of the metric system of weights and measures would be so much to the advantage of the work of education and commerce in this country that efforts should be made to bring the subject forward on every suitable occasion. We are, therefore, glad to see that the following resolution was passed at a general meeting of Convocation of the University of London on Monday:—"That this House is of opinion that, in the interests of commerce, science and education, legislation should be promptly undertaken to make compulsory in this kingdom, after a proper interval, the use of the metric system of weights and measures for all purposes."

PROF. ALFRED LODGE stated the case for reform in methods of teaching geometry at the annual meeting of the Mathematical Association held on Saturday last. He urged that a new text-book of geometry, framed more or less on the model

of books used in France, should be introduced as soon as possible to supersede Euclid's elements. Text-books adapted to modern needs are in use in the United States of America, and their chief characteristics are :—(1) The more orderly arrangement of propositions ; (2) the entire separation of theorems from problems of construction, hypothetical constructions being used in proving a theorem ; (3) the closer association of a proposition and its converse when both were true ; (4) the adoption of arithmetical notions and algebraic processes ; (5) the early introduction of simple *loci* ; (6) insistence on accurate figures drawn by accurate and practical processes ; (7) practice in exercises from the very beginning. It had been suggested to Prof. Lodge that he should add, "Attention paid to the various phases of a theorem as the figure changes, and (as the student progresses) to the easier forms of generalisation." The greater part of these improvements could be adopted at once, provided that the sanction of the great examining bodies could be obtained. A committee of the Association is being formed to cooperate with the committee of the British Association in advancing the reforms advocated in mathematical teaching.

THE work of the Sir John Cass Technical Institute, London, was inaugurated on January 15, when an introductory address was given by Sir William Roberts-Austen, K.C.B., F.R.S. The institute has been founded by the governors of Sir John Cass's Foundation, and is one of the London polytechnics aided by the Technical Education Board of the London County Council and by the City Parochial Foundation. The institute is situated in Jewry Street, Aldgate, and is readily accessible. It is provided with good laboratories for chemistry, metallurgy and physics, and on the art side with workshops and drawing rooms for the department of arts and crafts. Dr. C. A. Kohn is the principal of the institute. Sir William Roberts-Austen in his introductory address dealt chiefly with the subject of metallurgy. It was, he said, an industrial art depending for its success on what were called the applications of science, but he heartily wished that the term "applied science" had never been devised. There was no essential difference between what was called pure science and what was called applied. In industrial life they simply applied the facts of science to a particular set of conditions or to the solution of definite problems. This view was illustrated by reference to the process of cupellation, the history of which was described and illustrated by suitable experiments. The diffusion of solids was then referred to, and a summary was given of the steps that had led Sir William to the investigation of the diffusion of metals.

THE importance of geography in education was the subject of an address delivered by Mr. James Bryce, M.P., at the annual meeting of the Geographical Association held last week, Mr. Douglas W. Freshfield, president, being in the chair. The Association aims at the improvement of the teaching of geography by spreading the knowledge of all such methods as call out the pupil's intelligence and reasoning powers and make geography a real educational discipline, instead of merely loading the memory with names and isolated facts. After expressing his hearty sympathy with the objects of the Association, Mr. Bryce considered the place of geography in education under three aspects, viz., as the gateway to the physical sciences, the key to history, and the basis of commerce. In this country, as in Germany for some time, it is thoroughly realised by all progressive teachers that geography must be made as much as possible an experimental science—that the pupil's mind must be brought into contact with facts and not alone with words. The pupil taught to observe has it suggested to him how things are connected with one another ; he acquires the habit of looking at the country and asking himself what are the physical causes which make the district what it is, and what is the relation between those different causes. As to geography being regarded as the basis of commerce, Mr. Bryce said that the producer and merchant ought to know where each article could be best produced, where the raw material comes from, what are the conditions of labour, which are the best points of manufacture, where are the best markets, and what are the lines of communication and transport. Although the commercial man has to rely upon trained observers he would do better if he acquired geographical knowledge himself, because he could develop for himself certain lines of policy upon which he could conduct his operations ; his wider knowledge of the world would enable him to take, not only a more intelligent, but a more practically serviceable view of the action which in each particular case was to be taken, and which, of course, would be constantly shifting. If the heads of great business houses were thoroughly trained to observe these things and to look at them in a scientific way, a great deal would be done to enable the country to hold its place in the great commercial world.

IN view of the recognition with which scientific training is now meeting, as part of our educational system, some of the suggestions made at the Conference of Public School Science Masters on January 18 are of interest. Those responsible for the framing of the regulations for Army examinations were unanimously recommended by scientific men from all the great public schools, and from many others, to lay more stress upon the practical side of the science work. It was, further, suggested to them that quantitative work should be introduced and that physics should be given the place it deserves in the compulsory science papers. Moreover, what is to be sought is not knowledge-worship, but training, not the old-fashioned theoretical questions with which examiners find it so easy to elicit facts, but the construction of problems which, when worked out practically under their own eyes, will truly tell them the capabilities of the candidates. Testimony was also forthcoming that there are examiners who will take the trouble to examine in the latter way, and the meeting was in favour of allowing that greater scope to assistant practical examiners which they must have if large numbers of persons are to be examined at one time. The pernicious specialisation which takes place in schools as a result of the examinations for science scholarships at the Universities of Oxford and Cambridge was made abundantly clear, and some system advocated which will prevent this and at the same time ensure all boys in the school—and not the "intellectual refuse" and Army classes alone—having a proper scientific training for several years, whether they be classical or modern, literary or mathematical. A committee, it has been arranged, is to take up the matter. A sidewind during the discussion, as to whether classical boys do better than others in scientific work elicited the fact that at Woolwich, for instance, no rule one way or the other could be laid down. The necessity of culture as well as scientific education was a point that was touched upon, and might well form the subject of a future discussion. Biology as a school subject was rather pooh-poohed by one representative from Cambridge University, while its importance was just as strongly urged by a public school master. It came as no surprise to those familiar with what occurred last year, that a definite association was formed as a result of the conference which will arrange for similar and possibly more frequent meetings in the future. Principal Rücker has consented to become the first president of the Association of Public School Science Masters—a body the constitution of which will be somewhat elastic, as it is difficult to define what is a public school science master, but the title is sufficiently rigid to specify the character of the Association.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 20, 1901.—"The Anomalous Dispersion of Sodium Vapour." By R. W. Wood, Professor of Experimental Physics, Johns Hopkins University, U.S.A.

The modern theories of dispersion show that the effect of an absorption band is to lower abnormally the refractive index of the medium on the side of the shorter wave-lengths and raise it on the side of the longer wave-lengths. In some cases even the refractive index may fall below one on the blue side of the band, which means that light of a certain wave-length travels through the medium at a higher velocity than in a vacuum. Substances showing this peculiarity are exceedingly opaque to light, a thickness of a few wave-lengths absorbing completely all of the light for which this peculiarity exists.

It is quite possible to conceive of a medium with a strong absorption band in the middle of the visible spectrum having a refractive index greater than unity for all waves longer than the absorbed waves, and a refractive index less than unity for all shorter waves. A prism made of such a substance would deviate half of the spectrum in one direction and half in another direction, something in the manner of the direct-vision prism, except that the arrangement of the colours would be anomalous. Such a medium has been found in metallic sodium vapour, which is most beautifully transparent in addition to having the peculiarity

before mentioned. By means of prisms of sodium vapour it is possible to form a complete anomalous spectrum, in which all the colours between the extreme red and violet are present, with the exception of a very narrow range at the D lines. It has been found that the refractive index is one for the extreme violet, greater than one for all colours on the red side of the D lines, and less than one for all colours on the other side, the maximum and minimum values occurring, of course, close to absorptionbands (the D lines).

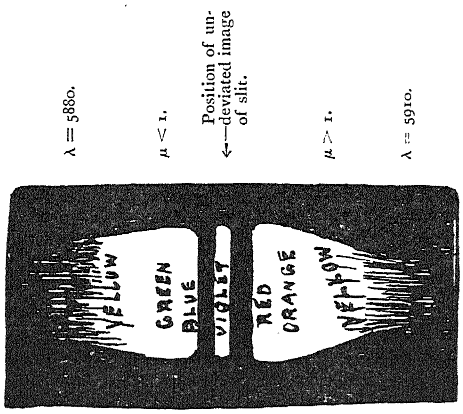

FIG. 1.

In the spectrum produced by a prism of sodium vapour the violet occupies the position of the undeviated image of the slit, the red and orange flaring off to one side, and the blue, green and yellow to the other, as is shown in Fig. 1.[1]

Inasmuch as sodium vapour appears to be the substance best adapted to class demonstration of anomalous dispersion, it is worth while to describe in some detail the apparatus by which the remarkable optical properties of the vapour can be exhibited, referring the reader to the original paper for a more complete discussion. (The paper is to appear also in the *Philosophical Magazine*.)

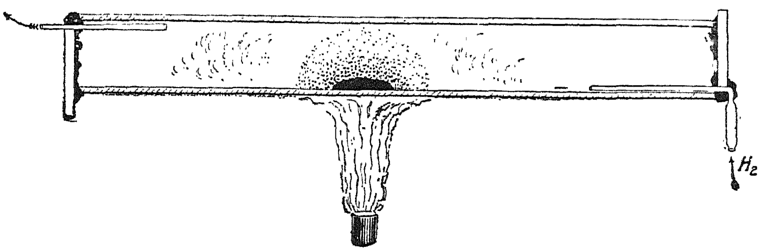

FIG. 2.

The first experiments were made with a large prism of cast iron, furnished with windows of mica or thin plate glass, in which the metal was heated in an atmosphere of hydrogen. Very beautiful results were at once obtained, but certain peculiarities of the vapour's action showed that the refraction was due chiefly to the action of a non-homogeneous medium, the planes of constant density being horizontal. Great trouble was caused by the windows, which soon became covered with a white deposit, which cut off most of the light. It being apparent, however, that the oblique faces played but a very small part, the effect being due almost wholly to the variable density of the vapour, it seemed best to make the most of this circumstance and dispense with the trouble entirely by removing the glass plates to such a distance from the heated vapour that no deposit took place. The arrangement finally adopted was simply a tube of glass about 30 cm. long, provided with plate-glass ends cemented on with sealing-wax. Hydrogen dried by passage over calcium chloride was conducted into and out of the tube by means of two fine glass tubes, arranged as shown in Fig. 2.

The diameter of the tubes should not be more than 2 mm., and they should lie close against the sides of the large tube in order not to cut off any of the light. The most suitable diameter for the large tube is 2 cm. The ends of the tube are first warmed and thickly coated with sealing-wax. One of the glass straws is placed in position, and a small piece of plate glass, previously warmed, applied to the end of the tube, any crevices around the straw being closed with wax. The leading-in tube is next placed in position and a piece of freshly cut sodium (about 5 mm. on a side) inserted. The other window is then cemented to the tube and the current of hydrogen started as soon as possible. Some experience is necessary to regulate properly the hydrogen stream during the experiment. When the tube is first heated much white smoke forms. If a stream corresponding to about one bubble per second is allowed to flow, the smoke will usually clear up in a few minutes and give little trouble. The tube should be heated by means of a Bunsen burner turned down low, the tip of the flame playing against the bottom of the tube. If a sodium flame is placed behind the tube the formation of the vapour can be watched, for it appears almost jet black against the flame, though quite colourless in white light. The behaviour of the vapour is somewhat peculiar. It grows out from the sodium globule as a dark atmosphere with a sharply defined surface, which clings to the globule with great tenacity. It resembles at first a thick growth of mould more than anything else, and a sudden gust of hydrogen scarcely moves it at all. A wire pushed up through it drags a certain amount above the free surface, in much the same manner as a stick pushed up through the surface of thick molasses would do. If the tube be inverted the black cloud clings to the upper surface, behaving, on the whole, like a very viscous mass. It is even possible to dip some of it up on a wire.

These peculiar physical properties of the metallic vapour have as yet only been studied in a very superficial manner, and they are mentioned now only because it appears that there is some connection between them and the optical behaviour of the medium.

The opinion is expressed that the apparent viscosity is an illusion; that the sharply defined surface is merely the boundary at which either condensation or chemical action (the hydrogen was not absolutely pure) is taking place. The process of dipping the vapour up on the wire might be explained by condensation on the wire followed by vaporisation. A more careful study of the physical behaviour of the vapour will be made some time in the future.

The apparatus employed in the study of the dispersion of the vapour was essentially identical with that used by Becquerel. The light of an arc lamp was focussed on the *horizontal* slit of a collimator, after traversing which the rays passed lengthwise through the dispersion tube. A second lens brought them to a focus on the slit of a spectroscope when the dispersion was to be studied by the method of crossed prisms, or in the focus of an eye-piece when the anomalous spectrum was to be viewed subjectively (Fig. 3).

The first experiments were made by the method of crossed

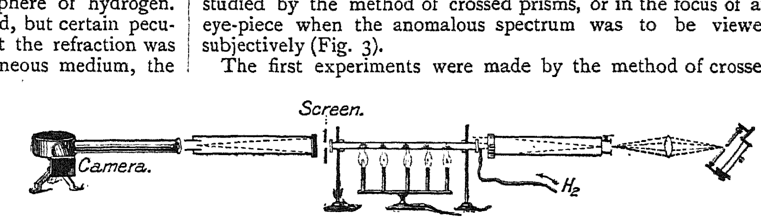

FIG. 3.

prisms, the spectrometer being furnished with a Rowland plane grating, which showed the sodium lines widely separated. It was at once apparent that far better results could be obtained with the dispersion tubes than had ever been observed with prismatic flames. The curved branches of the diffraction

[1] This spectrum is illustrated by a coloured plate in the original paper.

spectrum on each side of the D lines were perfectly sharp and steady, and the dispersion could be traced a considerable distance up and down the spectrum. On the slit of the spectrometer appeared, instead of the white image of the horizontal slit, a most beautiful anomalous spectrum of great brilliancy and purity. The spectrometer was at once removed and an eye-piece put in its place, when a most superb spectrum revealed itself (Fig. 1).

Before discussing this spectrum in detail it will be better to take up the results of the experiments made by the method of crossed prisms. On first heating the tube the curvature of the

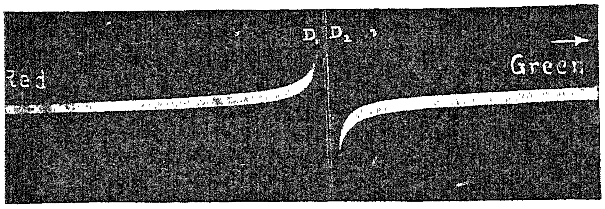

FIG. 4.

spectrum between the D lines as well as on each side is observed, the appearance being identical with that figured by Becquerel, but in a few seconds the vapour becomes so dense that total absorption of all the light between the lines occurs. The oppositely curved branches adjacent to the region of absorption extend rapidly up and down as the tube grows hotter, the ends finally passing out of the field of the instrument. A beautiful fluted absorption appears in the red and the greenish-blue, which finally blots out a region in the blue almost entirely. Meanwhile the curvature of the spectrum

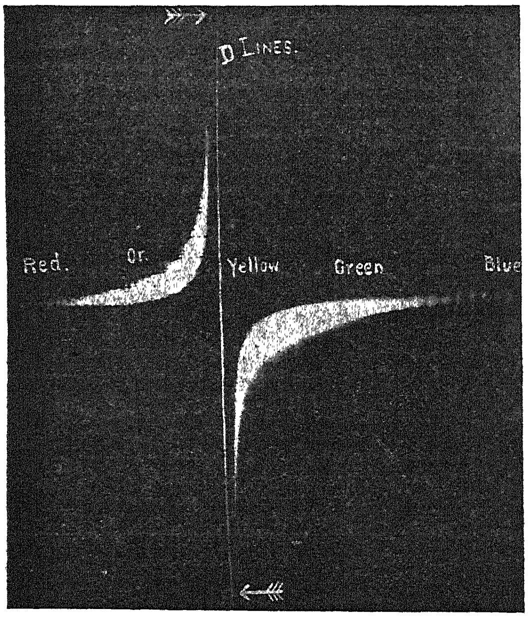

FIG. 5.

increases in a most remarkable manner, and the entire red end is lifted high above the green-blue end. As the density of the vapour increases the red gradually fades away, leaving only the yellow and green and the remote blue and violet, the curvature increasing all the while.

Figs. 4 and 5 are photographs of the continuous spectrum after dispersion by means of a prism of sodium vapour. They give a very good idea of what is seen with the apparatus arranged as shown in Fig. 3. The sodium lines were impressed on the plate by holding a sodium flame in front of the slit of the spectrometer after the exposure was over. In Fig. 5 the arrows indicate the points to which the curved branches could be traced in the original negative. Eye observations enable them to be traced much farther, for they are very feeble at the tips, and the light is not very actinic.

For the exhibition of the actual spectrum produced by a prism of sodium vapour a long dispersion tube with a battery of four or five prisms gives the best results. A small Bunsen burner should be used for each of the fragments of sodium, which should be at least 6 or 8 cm. apart. A coloured drawing of the spectrum, which has already been mentioned, was made when the spectrum was obtained in this manner. A single prism gives a very pretty anomalous spectrum, but the magnificent effect produced by the battery makes the slight amount of extra trouble well worth while. If the electric arc is employed as the source of light, the extreme violet will be found to occupy the position of the undeviated image of the slit (Fig. 1). Then comes the blue, sometimes in contact with the violet and sometimes slightly separated by a fine dark line, owing to the fact that the violet light comes from the fluted carbon band of the arc, which is separated from the blue by a comparatively dark region. Then comes a wide gap corresponding to light absorbed by the sodium vapour in the blue-green region (the channelled spectrum), and above this a beautiful flare of colour ranging from blue-green through grass-green to yellow. The red and orange portion of the spectrum is on the other side, or below the undeviated image, forming another brilliant flare of colour. It is separated from the violet by a wide dark band, due to the absorption in the vicinity of the D lines. If the density of the vapour is increased by heating the tube to a higher temperature, the red flare extends lower down, grows fainter, and finally fades away owing to the presence of the fluted absorption bands in the red. The green and blue persist, however, becoming more widely separated, but finally the green disappears almost entirely. It is best to arrange the gas cock so that the height of the flames can be controlled without leaving the eye-piece, for it is surprising how slight a change is necessary to completely alter the general appearance of the spectrum. The glass tube should not be allowed to cool until the experiment is at an end, otherwise it will immediately fly to pieces when the flame is again applied to it.

While glass answers very well if the experiment is to be of short duration, sheet iron is much more satisfactory. Suitable tubes can be made by any tinsmith. They should be made of thin sheet iron, and the turned-over seam should be hammered until a tight joint is formed. These tubes can be heated and cooled any number of times and can be kept in operation for an hour or two, at the end of which time the sodium is generally used up, a moss-like deposit of oxide gradually filling up the tube. The tubes can be used over and over again without deterioration, and are most satisfactory in every respect. Their only fault lies in their conductivity, the sealing-wax softening and the glass plates falling off; but this can be prevented by wrapping a strip of cloth around each end and wetting it from time to time. One tube was made with water jackets at each end, but it seems to have no especial advantage, and is more complicated. Porcelain tubes are quite satisfactory, but the iron is to be preferred on the whole.

By employing a tube of about 5 cm. diameter the anomalous spectrum can be projected, but the appearance is so very inferior to that of the phenomenon when seen subjectively that the method is not recommended.

Royal Astronomical Society, January 10.—Dr. J. W. L. Glaisher, F.R.S., president, in the chair.—In a paper on periodic orbits Mr. E. T. Whittaker communicated two theorems relating to the periodic solutions of the differential equations of dynamics and astronomy. The first theorem furnished a criterion for the discovery of periodic orbits; if a certain function of position be negative for all points of a closed curve and positive for all points of a curve enclosing this, then a periodic orbit exists in the ring-shaped space between the curves. The second theorem was concerned with an integral, the value of which when integrated over the region bounded by a periodic orbit is equal to the number of centres of force enclosed by the orbit.—Prof. H. H. Turner read a paper by Major Burrard, of the Indian Survey, on the attraction of the Himalaya Mountains upon the plumb-line in India. A chart was exhibited, showing a supposed underground source of attraction running across central India.—Lantern slides were shown of photographs taken by

Mr. Ritchey at the Yerkes Observatory of the nebula surrounding the new star in Perseus, and Mr. Newall described Prof. Kapteyn's suggested explanation of the apparent rapid motion of the nebula as shown in the photographs.—Mr. Lewis read a paper on the orbit of the binary star Σ 1639 in Coma Berenices. —The secretary read a paper by Mr. Robinson, of the Radcliffe Observatory, Oxford, upon a comparison of the visual and photographic magnitudes of Nova Persei.

Linnean Society, December 19, 1901.—Prof. S. H. Vines, F.R.S., president, in the chair.—Prof. G. B. Howes exhibited a marine organism received from Dr. Gilchrist, of South Africa. It measures 15 cm. in length, and is structureless and transparent, in section four-sided, with its angles prolonged and each intervening area concave. A central tubular cavity is present, and at one end a deep constriction, which may be due to wave-action or other artificial causes. Ideas of a ctenophoran, the cast-off test of a tunicate of the distoma type, of a myxicolid worm-tube, an egg-capsule, and others which had occurred, had all been discarded; and after having submitted the object to a dozen trained experts, he put it forward in the hope of obtaining a clue to its significance and zoological position. In commenting upon this exhibit, the president said he believed the occasion was probably the first in the history of the Society upon which an object had been laid upon the table to which no one could give a name.—Prof. Howes also exhibited a mounted specimen of the giant argulus (*A. scutiformis*) from a Japanese Tetrodon. —Mr. J. E. S. Moore exhibited the entire specimen and a microscopic preparation, with drawings, of a new polyzoon, encrusting the shell of Paramelania, dredged on the west coast of Lake Tanganyika, at a depth of 25 fathoms. He showed it to be typically gymnotæmatous, and to present characters most nearly suggestive of the marine genus Arachnidium.—Dr. C. W. Andrews gave a short account of his recent visit to Egypt, and showed lantern-slides illustrating some of the districts in which vertebrate fossils were collected. The most important journeys were to Mozara with Mr. T. Barrow, and to the Fayûm with Mr. H. J. L. Beadnell, officers of the Egyptian Geological Survey. In the former locality remains of Mastodon, Brachyodus and other vertebrates of Lower Miocene age were found; and in the latter a large series of bones from Middle and Upper Eocene beds was collected. These bones include a number of very interesting forms, some of which (Palæomastodon and Mœritherium) seem to be early proboscidians, and indicate that that group originated in an Ethiopian land-area which became united to the Palæarctic land in Oligocene times. A number of plaster-casts of some of the more important specimens were shown.—Mr. Miller Christy exhibited and made remarks on a specimen of White's Thrush, *Turdus varius*, Pallas, which had been shot near Clavering, in Essex, so long ago as January 1894, and had been preserved for Mr. Rolfe, but had only recently been identified as a rarity. Mr. J. E. Harting stated that about the same time another bird of this species, which he had seen, had been procured near Southampton, and that the two might well have arrived in company from Siberia. After pointing out the geographical distribution of the species and its distinguishing characters, he exhibited coloured figures of the egg, which is one of the rarest in collections; and, for comparison, a figure of the egg and nest of the allied *Turdus lunulatus* of Australia.—The Rev. John Gerard exhibited a nest of the sand-martin (*Cotile riparia*) made within the nest of a dipper (*Cinclus aquaticus*), found near Bashall Hall, Yorkshire, in which eggs of the former bird had been laid and hatched after the latter had ceased to occupy it.—Mr. S. Pace exhibited specimens of the common Torres Straits snail *Planispira* (*Trachiopsis*) *delessertiana*. He likewise exhibited a specimen and drawings from life of a rare pelagic tectibranch, *Euselenops* (*Neda*) *luniceps*, taken in Friday Island Passage, Torres Straits. —Mr. S. Pace read a paper on the gasteropod Pontiothauma, Sm., giving an account of the anatomy of this remarkable genus, with special reference to the proboscis and its associated parts, as observed in a specimen from the Indian seas, furnished some years ago by Dr. Alcock, of the Calcutta Museum.—Mr. F. Chapman read a paper on the Ostracoda collected round the Funafuti Atoll. This collection, which had been placed in his hands for examination and description by Prof. Judd, C.B., F.R.S., was obtained from various sources during the work of the expedition for the purpose of boring in the Atoll. The specimens represented the recent deposits obtained by dredging outside the Atoll, chiefly at moderate depths, but many were also selected from the dredgings in the lagoon, as well as from the beach-sands, the deep-sea deposits and the sands from the Atoll boring. The total number of species was fifty-two, six of which were found to be undescribed. The occurrence of the genus Limnocythere was considered noteworthy on account of its fresh-water habit.

Royal Meteorological Society, December 15, 1901.—Mr. W. H. Dines, president, in the chair.—The Symons gold medal was presented to Dr. Alexander Buchan, F.R.S., for his work in connection with meteorological science.—The president in his address dealt with the theory of probability applied to various meteorological problems. He considered that for all practical purposes weather conditions may be looked upon as purely accidental, and that we may apply to them the laws of chance. They are not by any means in reality a matter of chance, for although we cannot discover it, there is doubtless a cause for each kind of weather, normal or abnormal. After speaking upon the subject of weather forecasting, he dealt with the question, How long is required to obtain a true average? He has come to the conclusion that ten years' temperature observations give a mean of which the probable error is a little under one degree; thirty years reduce this to half a degree, fifty years to one-third of a degree, and a hundred years to one-quarter of a degree. After dealing with barometer observations and rainfall, he proceeded to speak of weather almanacs, cycles, &c. In conclusion he said that meteorology is far more than a statistical science, and is very closely dependent upon theoretical mechanics and thermodynamics, and in the application of these subjects to meteorology lies the best hope of advance. The council for the ensuing year were then elected, Mr. W. H. Dines being the president and Mr. F. C. Bayard and Dr. H. R. Mill secretaries.

PARIS.

Academy of Sciences, January 13.—M. Bouquet de la Grye in the chair.—On the periods of double integrals and on a class of linear differential equations, by M. Émile Picard.—The preparation and properties of the hydride of sodium, by M. Henri Moissan. Metallic sodium is attacked by hydrogen gas at a temperature of about 400° C., the hydride thus formed dissolving in the excess of metal, from which it can be isolated in a slightly impure state by treatment with liquefied ammonia at −40° C. Pure sodium hydride was finally obtained by heating sodium wire in hydrogen at 370° C., keeping the upper portion of the tube slightly cooler. Under these conditions the hydride condenses on the cooler part in crystals, which upon analysis proved to be NaH. It is attacked by the slightest trace of water and catches fire in moist air. The hydride is attacked by gaseous fluorine and chlorine, but remains unaltered in the presence of liquid chlorine at −35° C. It resembles potassium hydride in its powerful reducing properties.—The cultivation of lucerne upon soils without lime, by MM. P. Dehérain and E. Demoussy. Lucerne and clover grow feebly in soils without lime if the bacteria-producing nodosities are present. The addition of lime increases the vigour of growth in both cases.—On integral parameters, by M. Alf. Guldberg.—On the theory of entire functions, by M. Pierre Boutroux.—On radioactive bodies, by M. P. Curie and Mdme. S. Curie. The authors have taken two hypotheses as guiding principles in their researches on the radioactive bodies; that radioactivity is an atomic property of bodies, and that each atom of a radioactive substance behaves as a constant source of energy. Experiments carried out over several years show that for uranium, thorium, radium and probably actinium, the radiant activity remains constant if the chemical and physical state of the radioactive body remains the same. Polonium alone appears to be an exception to this rule. —A principle relating to the distribution of the lines of magnetic induction, by M. Vasilesco Karpen. The principle is laid down that in a magnetic medium submitted to the action of a certain number of magnetomotive forces, the course of the lines of induction is such that the intrinsic energy of the medium is a maximum.—On the difference of potential and the deadening of the oscillatory spark, by M. F. Beaulard. A correction of an arithmetical error in a previous paper.—Telephony without wires through the earth, by M. E. Ducretet. By the use of a microphone, messages were transmitted through the earth with remarkable clearness, without any of the secondary noises so annoying in telephony with conducting wires.—The influence of low barometric pressures on the frequency of the polar aurora, by M. H. Stassano. A clear connection is traced between the frequency of the appearance of the aurora and a low

barometer.—The earthquakes due to folding in the Erzgebirge, by M. F. de Montessus de Ballore. The numerous slight earthquakes in this region are traced to the effect of three long folds in the strata, the Erzebirge being the longest and highest of the three.—On the aberration of sphericity of the eye, by M. Georges Weiss.—The preparation and properties of strontium hydride, by M. Henri Gautier. A strontium-cadmium alloy containing about 45 per cent. of strontium is heated in a current of hydrogen to a dull red heat. The hydrogen is slowly absorbed and the cadmium volatilised. Towards the end of the operation the temperature is raised until the mass is fused. Analyses of the compound showed that its composition was SrH_2. It proved to be analogous both in composition and properties to the calcium hydride of Moissan.—On the chemical equilibrium of the iron-carbon systems, by MM. Georges Charpy and Louis Grenet. The theory of Bakhuis-Roozeboom on the constitution of the compounds of iron and carbon, although complete from the theoretical side, has met with some objections from the practical point of view. The separation of graphite would appear to be largely conditioned by the amount of silicon present. An experimental study of the effect of silicon is given in the present paper.—On the thermoelectricity of steels and nickel-steels, by M. G. Belloc. The proportions of nickel in the nickel-steels studied varied from 5 to 35 per cent. The general form of the curve giving the relation between the electromotive force and the temperature for platinum-nickel steel couples is parabolic, the alloy containing 5 per cent. of nickel being exceptional in this respect. The steels containing 5 per cent. and 28 per cent. of nickel at about 400° to 500° C. show brusque variations, indicating molecular transformations. The 28 per cent. nickel steel is remarkable for its high neutral point and the great electromotive force developed.—The action of mixed organo-magnesium compounds upon trioxymethylene, by MM. V. Grignard and L. Tissier. Trioxymethylene reacts slowly at the boiling temperature upon an ethereal solution of the organo-magnesium compounds with the formation of primary alcohols. Numerous alcohols have been thus prepared synthetically, and the method appears to be of wide generality. Thus starting with ethyl bromide, normal propyl alcohol is obtained with a 65 per cent. yield; the reaction also holds in the aromatic series.—The preparation and properties of the imido-dithiocarbonic esters, by M. Marcel Delépine.—On the inversion of saccharose, by M. P. Petit. An attempt at the direct measurement of the heat of inversion of sugar.—On the solubility of calcium phosphate in pure water, by M. A. Rindell.—On the methods for the volumetric estimation of copper, iron, antimony, zinc dust, sulphur in sulphides, and glucose by means of stannous chloride, by M. Fred. Weil.—On the geographical distribution and adaptation to fresh water of some marine forms, by MM. C. Vaney and A. Conte.—On a crustacean commensal with Pagurus, *Gnathomysis Gerlachei*, a type of a new family of schizopods, by MM. Jules Bonnier and Charles Pérez.—The action of tannins and colouring matters on the activity of yeasts, by M. A. Rosenstiehl.—The mechanism of synthesis of an isomeric leucine, by MM. A. Etard and A. Vila. Leucine derived synthetically from amyl alcohol is different from biological leucine.—On the extraction of boletol, by M. Gabriel Bertrand.—On the fracture of the fore-arm due to a premature explosion in an automobile motor, by M. H. Soret.—The discovery of the mammoth and of a Palæolithic station in Basse-Provence, by M. Repelin.—On the structure of the subterranean hydrographic network in limestone regions, by M. F. Fournier.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 23.

ROYAL SOCIETY, at 4.30.—(1) Mathematical Contributions to the Theory of Evolution. XI. On the Influence of Natural Selection on the Variability and Correlation of Organs; (2) On the Correlation of Intellectual Ability with the Size and Shape of the Head. Preliminary Notice: Prof. K. Pearson, F.R.S.—A Short Description of the Culicidæ of India, with Descriptions of New Species of Anopheles: F. V. Theobald.—The Affinity of Tmesipteris with the Sphenophyllales: Prof. A. P. W. Thomas.—On the Excretory Organs of Amphioxus: E. S. Goodrich.—On the Mechanism of the so-called "Peripheral Reflex Secretion" of the Pancreas. Preliminary Communication: Dr. W. M. Bayliss and Prof. E. H. Starling, F.R.S.

THE ADVANCEMENT OF NATURAL KNOWLEDGE.

THE *London Gazette* announces that a petition for incorporation has been presented to His Majesty on behalf of a new body, "The British Academy for the Promotion of Historical, Philosophical and Philological Studies." An explanation has been given that the object of this institution is to do for the various departments of "literary science" what the Royal Society has achieved for "natural science." The causes which have led up to this proposal may be stated as follows. At a meeting of the representatives of the chief European and American academies held at Wiesbaden in October 1899, an International Association of the principal Scientific and Literary Academies of the world was decided upon. Most of the academies represented are divided into two sections, a section of natural science and a section of historico-philosophical science. And on this ground the scheme provided for the division of the new association into two sections, "scientific" and "literary," the word "literary" being used only as a short title to embrace the sciences of language, history, philosophy, archæology and other subjects the proper study of which is based on scientific methods. At the conference the representatives of the Royal Society, not feeling themselves competent to represent the United Kingdom in the philosophico-historical section, were unofficially requested to take such steps as might be possible to fill this gap in the future.

The next steps taken may be gathered from the Report of the Royal Society Council presented to the Society on November 30, 1901.

The secretaries, apparently in fulfilment of their undertaking at Wiesbaden, wrote on the subject to the president of the Society of Antiquaries, Viscount Dillon, on November 21, 1899. A meeting was called at which, among others, several fellows of the Royal Society and of the Society of Antiquaries were present. The conclusion arrived at was that the idea of an academy to represent the philosophico-historical subjects formed by the simple federation of existing societies was not one which appeared to meet the views of those present.

At the same time the late Prof. Sidgwick drew up a plan which was approved by several of those attending the meeting and "of which the resolution passed at that meeting might be considered a part." This plan pointed out that the Royal Society might enlarge its scope, and include a section corresponding to the "philosophico-historical" and "philological" division of the German Royal Academies and Societies.

The next step taken was the reference of the matter to a special committee of the Royal Society.

The Committee point out that four possible ways of dealing with the matter were submitted to them :—

"(1) The creation of an organisation independent of the Royal Society, though possibly in some way connected with it, in which case they might both form parts of some larger body, as, for instance, the French Academies form parts of the Institute of France.

"(2) The creation of two 'Academies' within the Royal Society, one of Mathematics and Natural Sciences, the other of Philosophy-History, each Academy having its own Council, Secretaries and President, and the President of each being in turn President of the whole Society.

"(3) The creation of two or of three 'Sections' of the Royal Society, either A and B, corresponding to the Academies just named ; or A, Mathematical and Physical Sciences ; B, Biological Sciences ; C, Philosophico-Historical Sciences.

"(4) The election of some 25 to 50 Fellows representing the Philosophico-Historical subjects, to serve as a nucleus, and the creation of three or four committees, similar to those already existing, viz., one for Ethnography and Archæology, one for Philology, one for Statistics and Political Economy, and one for Psychology, the Officers and Council remaining, so far as statute and enactment are concerned, precisely as they are at present."

After these schemes had been formulated they were discussed at an interview with a number of representatives of the philosophico-historical sciences. Concerning this interview we read :—

"They all expressed themselves in favour of any effort for the corporate representation of those sciences being associated in some way or other with the Royal Society. They seemed unanimous in feeling the great desirability of the organisation and official representation of the Philosophico-Historical subjects, both on the ground of the general encouragement of their pursuit, and also, and more especially, as a means of developing the more scientific methods of treating those subjects.

"The general opinion of these gentlemen upon the practical courses discussed in the Report seemed to be in favour of the plan numbered (3) in the Report, but, recognising the practical difficulties in the way of carrying out any such scheme immediately, they were generally in favour of an effort being made on the lines laid down in plan numbered (4) as a beginning, in the belief that should its adoption lead, as they believe it would, to greater activity in this country in the studies in question, there might ultimately develop out of it some more formal organisation, such as is contemplated in the other plans submitted."

It is frankly stated that the Committee were much impressed by the concurrence of opinion among the gentlemen whom they consulted and by the high value they set on the inclusion within the scope of the Royal Society's action of the subjects they represented.

After the Report of this Committee was sent in to the Council, a special meeting of the Society was called for May 9, 1901. Unfortunately there is no record of what took place at it, but at the Council meeting in June the following resolution was passed:—"That the Council, while sympathising with the desire to secure corporate organisation for the exact literary studies considered in the Report, is of opinion that it is undesirable that the Royal Society should itself initiate the establishment of a British Academy."

The *Times* now tells us that on June 28, 1901, a month after this resolution was arrived at, those interested in the proper representation of the "literary" subjects met at the British Museum and

"after long and careful deliberation resolved to promote the establishment of a British Academy of Historical, Philosophical and Philological Studies on conditions which would satisfy the requirements of the International Association of Academies. It was further decided that the Academy should petition for incorporation by Royal

Charter, and that the nomination of the first Fellows under the proposed charter should be forthwith taken in hand. Before the close of last year, on December 17, the British Academy held its first meeting at the British Museum and petitioned His Majesty for incorporation by Charter."

According to the draft Charter, the petitioners will be the first Fellows of the Academy, and the President and Council will be elected by the Fellows from amongst their own number. New Fellows will be elected at a general meeting of the Fellows.

The announcement in the *London Gazette* states that His Majesty has referred the petition to a committee of the Lords of the Council. Notice is further given that all petitions for or against such grant should be sent to the Privy Council Office on or before February 14 next.

The following letter from Sir Norman Lockyer appears in the *Times* of yesterday (January 29):—

SIR,—All students of natural knowledge in this country should agree as to the importance of the step recently taken to organise certain branches of it, concerning which you have given your readers much information. There are, however, some points connected with the movement on which you have not yet touched. Will you permit me to refer to them and the conclusion to which they lead?

The petition to His Majesty for a charter to embrace the organisation of historical, philosophical and philological sciences was rendered necessary by the action of the council of the Royal Society, who declined to "initiate the establishment of a British Academy" dealing with these subjects. But, in the first instance, the desire of those interested in the movement was that the Royal Society might include in itself a section corresponding to the philosophico-historical and philological division of the Continental academies; it was not a question of establishing a British Academy.

To consider the matter in this form a committee of the Royal Society was appointed, and its report has recently been published. In this report we have the following reference to the subjects dealt with by the historical and philological sections of foreign academies:—

These subjects have, in England, hitherto remained unorganised—that is to say, the workers in each one of them have been brought into little or no relation with the workers in each of the others. Societies have been founded for the promotion of some of them, but these societies are not linked together by the membership of their leading members in one body of recognised authority and influence, such as the Royal Society provides for the investigators of various branches of mathematical, observational, and experimental science.

The advantages which the gathering into one body of the men most eminent in the subjects above specified have secured in Germany, France, Italy and Belgium do not exist here, and the absence of any effort to secure them has often excited the surprise of learned men in those countries. Neither is there in England any series of Transactions similar to those of the leading academies of Continental Europe, in which records of the most fruitful inquiries in those subjects, or even systematised references to such inquiries, may be found.

We are next told that the following reasons, among others, have been suggested by eminent men as making it desirable that the Royal Society should take action in the matter:—

Assuming the organisation of the above subjects to be called for in the general interest of the intellectual progress of the country, the Royal Society can promote their organisation more effectively than could be done by the persons who are occupied in the study of them, because these persons have no sort of combined corporate existence, and no voluntary group of them would appear to have a proper *locus standi* for appealing to the public or approaching the Government in order to attain the object sought.

It has been urged on general grounds that the inclusion by the Royal Society of a section corresponding to the philosophico-historical and philological divisions of the German academies would strengthen the society by broadening the range of its scientific activity and increasing its influence; and would be to its advantage inasmuch as such a course would anticipate and thereby make needless the formation of an association which, by gathering the subjects within its scope, might to that extent be in rivalry with the Royal Society, and tend to narrow the legitimate range of its activity.

And next comes the most important part of the report, indicating that in the past, and by the three charters granted by His Majesty Charles II., the subjects under discussion were, and should now be, held to refer to "natural knowledge," and, therefore, should be dealt with by the Royal Society:—

The society exists for the promotion of natural knowledge. The interpretation of the term "natural knowledge," according to the present practice of the Royal Society, assigns to it a range from mathematics to the various biological sciences, and this secures the inclusion of the scientific study of man in his biological relations. . .

It is evident that the charters have never been interpreted as confining the "studies" of the society to "further promoting by the authority of experiments the science of natural things and of useful arts" in the strict modern meaning of those words. Indeed, the second charter in terms empowers the society to hold meetings "for the examination and investigation of experiments and of natural things," and both charters authorise it to enjoy "mutual intelligence and affairs with all and all manner of foreigners" . . . "in matters or things philosophical, mathematical, or mechanical." The provisions of the first statutes that the business of the society at its meetings shall be "to order, take account, consider, and discourse of philosophical experiments and observations; to read, hear, and discourse upon letters, reports, and other papers containing philosophical matters; and also to view and discourse upon rarities of nature and art," and the long and uninterrupted usage to receive papers on observational sciences, such as geology, or on pure mathematics, certainly do establish a *contemporanea expositio* which must be taken into account as *optimus interpres* and *fortissima in lege*.

Even had papers upon philological, psychological, or other subjects been entirely absent, no stress could be laid upon that fact, if in the opinion of the society those subjects have, under modern methods of treatment, become observational sciences, and as fully parts of "natural knowledge" as those subjects which were recognised as such at the epoch of the foundation of the society.

It would clearly be *ultra vires* for the society to resolve to receive a new class of papers, incapable of being regarded either in subject-matter or in scientific treatment as in the same category as those which have hitherto been received. But it would not be unlawful for the society to determine to receive papers on subjects not hitherto regarded as properly within its scope if it came deliberately to the conclusion that, in view of the scientific method in which they were now being treated, those subjects ought not to be excluded from its study.

The committee was not content with expressing its own view on this important matter; it privately consulted two high legal authorities, whose opinion led the committee to believe, in confirmation of the views above stated, that the inclusion within the scope of the society of such subjects as have been referred to, if treated by scientific methods, is "within the powers of the society."

Two extracts from the first charter granted by Charles II. alone seem to establish this conclusion. The charter begins as follows (I give the English translation as it runs in the "Record of the Royal Society, 1897"):—

Charles II., by the grace of God King of England, Scotland, France, and Ireland, Defender of the Faith, &c., to all to whom these present Letters shall come, greeting.

We have long and fully resolved with Ourself to extend not only the boundaries of the Empire, but also the very arts and sciences. Therefore we look with favour upon all forms of

learning, but with particular grace we encourage philosophical studies, especially those which by actual experiment attempt either to shape out a new philosophy or to perfect the old. In order, therefore, that such studies, which have not hitherto been sufficiently brilliant in any part of the world, may shine conspicuously amongst our people, and that at length the whole world of letters may always recognise us not only as the Defender of the Faith, but also as the universal lover and patron of every kind of truth: Know ye, &c.

Of the "Fellows" we read later on:—

The more eminently they are distinguished for the study of every kind of learning and good letters, the more ardently they desire to promote the honour, studies, and advantage of this Society . . . the more we wish them to be especially deemed fitting and worthy of being admitted into the number of the Fellows of the same Society.

"Every kind of learning and good letters" seems to me pretty general, and it does not seem improper to take the words "philosophical studies," in connection with Bacon's definition of philosophy, as dealing with a threefold division, of matters divine (supernatural), natural, and human, which also, perhaps, explains the subsequent insistence upon natural, as opposed to supernatural, knowledge.

But, without labouring this point further, I suggest that subjects the study of which by scientific methods increases the sum of natural knowledge must all stand on the same footing. I use the word "scientific" in its widest, which I believe to be the truest, sense, as including all additions to natural knowledge got by investigation. Human history and development are as important to mankind as the history and development of fishes. The Royal Society now practically neglects the one and encourages the other.

It is possible, then, to say the least, that the present general action of the society, and I say general, because the action changes from time to time, is really not in accordance with its charters; it certainly is not with its first practice. The charters make the society the head centre of the intellect of the kingdom engaged in making new natural knowledge, and therefore until these charters of King Charles II. are abrogated or revised there is no place logically for a new charter by King Edward VII. giving power to a new body to deal with the subjects the duty of the organisation and encouragement of which was previously committed to the Royal Society.

There can be no question that the gradual departure of the action of the Royal Society from the course laid down in the charters, and actually followed for a time, has been the gradual expansion and increased importance of experimental and observational methods of work, which of themselves are sufficient to employ the existing administrative machinery. But, if the whole work cannot be done inside the society as it exists at present, the question arises, Cannot some be organised side by side with it? Here, again, there may be difficulties; but, as the committee wisely say with regard to the first proposal:—

We are far from intending to express an opinion that any difficulties of detail ought to prevent the important issues involved from being fully considered in their largest bearings, having regard to the great benefits which might be expected to result to the progress of the philosophico-historical studies, and possibly to the Royal Society itself, from the inclusion of those studies within the scope of the society's action.

It is right that I should say that the Royal Society Council, in the resolution from which I have already quoted, expresses sympathy with the desire to secure a proper representation of the subjects now in question, and did not refuse to include them within itself, although its action may give colour to the belief in such an effect.

At present the Royal Society is the unique recognised centre of the general scientific activity in this country.

Will it be conducive to the interests of science, or even of the Royal Society itself, that in future there should be two entirely separate centres?

But will not this state of things be brought about if, without any general consideration, a charter is at once granted to the new body?

The important thing to secure is that the two bodies dealing with the two great groups of scientific subjects shall form part of one organisation—some enlarged Royal Society. What the *nexus* shall be is a matter of such subordinate importance that I do not propose now to refer to it further.

May not this present difficulty, Sir, be really a blessing in disguise? Does it not merely emphasise the activity of the scientific spirit and the employment of the scientific method in new regions, and suggest that the time has arrived, at the beginning of a new century and a new reign, for doing for the science of to-day what Charles II. did for the science of the seventeenth century—that is, organising and coordinating it on a broad basis?

It is clear that the question so wisely referred by His Majesty Edward VII. to the Privy Council is no light one, for the acts of a previous King of England and the future development of British science are involved. The present confusion is great and will become greater if a new charter is granted without a comparison and possible revision of the existing ones; and, short of an inquiry, by a Royal Commission or by some other means, to consider the question, it is difficult to see how the proper organisation of natural knowledge in the future can be secured.

It is fortunate that there is ample time for this important matter to be considered carefully in all its bearings, for not till 1904 can any British representation of the philosophico-historical subjects be considered by the International Association of Academies.

May I finally be permitted to say, Sir, how entirely I agree with the remarks in the leading article in the *Times* of the 16th inst. concerning the importance of organising literature as well as science? Science has undoubtedly gained by the charters of Charles II., and on this ground alone it may be urged that literature will be a gainer if it also is similarly organised. Certainly the most impressive sight I saw in Paris last year, when attending the first meeting of the International Association of Academies as a Royal Society delegate, was the reception of a new literary member of the Académie Française. The combination of troops representing the Government and members of other academies representing the Institute of France formed a picture which is not easily forgotten; it was one also to set one thinking.

I am, Sir, your obedient servant,

NORMAN LOCKYER.

THE EIFFEL TOWER.

La Tour Eiffel en 1900. Par M. G. Eiffel, Officier de la Légion d'Honneur. Pp. 363. (Paris: Masson and Co., 1902.)

IN a handsome volume, profusely illustrated with engravings and photographs, M. Eiffel has given an elaborate account, from its earliest conception, of the lofty structure that will always bear his name, and of the mechanical devices which have secured its success, both as a worthy monument of the art of construction and as a source of delight to the millions who have ascended it. We understand and regret that this monograph in some measure owes its appearance to the attacks of detractors, and it is intended to furnish a complete answer to those who, disapproving of the structure, have commented on its puerility and its uselessness. This ill will, well pronounced in the early days of the structure, and to which

M. Eiffel refers at length, has possibly revived since the falling off of receipts on the occasion of the last exhibition, and the well-earned reputation of the author may have suffered in consequence. Certainly no less than three descriptions of the Tower have emanated from the eminent engineer in a short space of time. The first, entitled "La Tour de trois cents Mètres," was an *ouvrage de luxe*, a massive folio volume with sixty-seven plates, also in folio. This work, intended for experts, has been presented to various public libraries and scientific societies, and will be consulted with interest by those engaged in similar projects of construction. Next appeared, in a more handy form, "Travaux Scientifiques exécutés à la Tour de trois cents Mètres," which, though not generally circulated, was intended to form a complete refutation to those who still urged the plea of inutility against the structure. The present volume appears to follow a middle course between these two, the author giving an account of the history of the construction of the Tower, the modifications that were suggested, after the experience gained in 1889, to make it more accessible to visitors in 1900, together with some account of the scientific investigations which this unique structure rendered possible or facilitated by reason of its height and form.

We have here, therefore, a complete history of the building from the date of its proposal in 1886 up to the present time, and of necessity many of the details have already appeared in the public journals, while the authors of the scientific work that has been carried on in connection with it, having contributed their results to various scientific bodies, have had them published in due course, and these have been commented on in our columns from time to time. As an example, one may refer to M. Janssen's researches on the telluric origin of the lines of oxygen in the solar spectrum, which were carried out in 1889. The value of the book consists in the completeness of the historical details and the ready access it offers to much that has been accomplished in connection with the Tower, particularly in the way of meteorological observations. M. Eiffel naturally thinks it a complete answer to his detractors, but whether this be so or not, it is impossible not to recognise that the management has welcomed with loyalty and assistance every scientific project that has been recommended to its consideration. One gathers that in the view of the promoters, the Tower was never intended to be either a scientific laboratory or a judicious pecuniary investment. We may quote here M. Eiffel himself:—

"Il me semble que, n'eût elle pas d'autre raison d'être que de montrer que nous ne sommes pas simplement le pays des amuseurs, mais aussi celui des ingénieurs et des constructeurs qu'on appelle de toutes les régions du monde pour édifier les ponts, les viaducs, les gares et les grands monuments de l'industrie moderne, la Tour Eiffel mériterait d'être traitée avec consideration."

And again:—

"Étant la plus saisissante manifestation de l'art des constructions métalliques par lesquelles nos ingénieurs se sont illustrés en Europe, elle est une des formes les plus frappantes de notre génie national moderne."

Looked at from this point of view, its existence is its justification. It accomplished what was demanded of it, and its scientific applications, useful as some of them may be, are no more than an ornamental fringe to the main design.

In 1889 nearly two million visitors paid for admission or ascent, and the lifting apparatus had been taxed to the extent of carrying 23,000 persons in a day. With the view of offering greater accommodation on the occasion of the exhibition in 1900, when as great or greater numbers of visitors might be expected, it was determined to increase the accommodation on the various platforms and to rearrange the mechanism of the lifts so that a greater number of ascents could be made per hour. The alterations, necessarily of a costly character, are described in very great detail, and when completed provided for the partial or complete ascent of 3120 passengers per hour, instead of 2680 per hour, as in 1889. Or regarded from another point of view, while the total receipts under the old system could not exceed 5240 francs per hour, under the new arrangement, with a lower tariff, the hourly receipts could amount to 7120 francs per hour. A great deal of work had to be effected, and the manner of its accomplishment, interesting to experts, will be found set out with great clearness and precision. How the sanguine expectations were disappointed is a matter of history, and the falling off in the number of visitors to about one-half is to be regretted; but the efficiency of the arrangements and the success with which they worked should be a matter of congratulation from an engineering point of view.

Having disposed of these mechanical arrangements, to which are added some interesting statistics connected with the financial side of the question, M. Eiffel gives some account of the various scientific purposes to which the Tower has been put during the last eleven years. These, referring to meteorology, to atmospheric electricity, to the construction of a manometer for high pressures, and a variety of other researches, have been mentioned in these columns at the time the different physicists engaged in the work published the results of their investigation. Although mention has already been made of wind observations in connection with the Tower, notably in vol. xlix. p. 596, and li. p. 181, we are tempted to return to this question and give the results of a simple investigation conducted by M. Eiffel to detect the amount of motion that the structure experienced under the influence of a high wind. It will be remembered that the opponents to the scheme of construction in the early days made a strong point of the difficulties that would ensue from excessive wind pressure, and the point is interesting, not only on that account, but because a great deal of loose information is current concerning the motion of tall chimneys and steeples. Anemometry, when applied to considerable areas, is not in a very satisfactory condition, and the necessary strength to be given to buildings is more or less a matter of conjecture and experience. M. Eiffel's method of observation was exceedingly simple. On the third platform, at a height of 309 m., was placed a diagram of concentric circles alternately coloured white and red, each 20 mm. in breadth, and ten in number. The centre of this target, if it may be so described, was made to coincide with the intersection of the cross wires of a solidly mounted theodolite at the base of the eastern pillar. It seems to have been assumed that the telescope

would not move, and the observation was effected by noticing the circle on the diagram which came under the intersection of the cross wires. It is not very clear how the motion in the line of sight was measured, or how the effects of foreshortening were removed. There was no illumination, and the observations were confined to daylight. The general effect of the wind is to make the top of the Tower describe an ellipse, and several diagrams are reproduced showing the effect of the greatest storms. The maximum displacement occurred during the storm of December 20, 1893, when the major axis of the ellipse was 0·10 m., and the minor axis 0·06 m. The time occupied in the description of the ellipse would have been interesting, but is not given. The measured velocity of the wind at the moment of observation is recorded as 31·8 m. per second, or 71 miles per hour. During this storm a velocity of 44 m. per second, or 98 miles per hour, was recorded, but at that moment the major axis of the ellipse was only 0·06 m. This seems to have occasioned M. Eiffel some surprise, but fortunately these excessive gusts are generally operative over a very small area, and the total wind force on the Tower is not to be measured by that experienced at a point very near the anemometer. The same apparatus has served for the measurement of the effects of temperature. The curves traced are generally of a complex character, depending on the position of the sun, and consist mainly of small excursions into the north-west and west quadrants. An example is given of the motion on a very hot day in August, when the centre of the diagram practically traced an elongated ellipse, 24 cm. in length, parallel to the east and west direction.

The researches summarised in the volume appear to be rather unequal in value, and a very small connection with the Tower affords a sufficient warranty for their introduction. Thus we get some account of the recent balloon ascent of M. Santos Dumont, because it was a part of the scheme for testing the capacity of giving definite direction to such an apparatus that the Eiffel Tower should be included in the closed curve to be described by the aëronaut. Perhaps, however, one underestimates the part played by the Tower in this instance, for M. Emmanuel Aimé, slightly changing the well-known aphorism of Voltaire, assures us if the Tower did not exist it would be necessary to invent it for the necessities of aërostation. It seems, however, that M. Dumont prefers to pursue his experiments where he gets no assistance from the lofty structure. This tendency to stray from the subject is still more noticeable in the appendix, where we get a chapter "renfermant une notice sur les travaux exécutées par mes établissements industriels de 1867 à 1890." We have no desire to quarrel with M. Eiffel on this ground. He has carried out many great and difficult works in various parts of the world, and is to be congratulated on the success that has generally attended them. In forming our estimate of what he has accomplished for engineering science he should not be judged simply by the most popular or conspicuous example of his talent, but by the work of his whole career, which he may contemplate with complete satisfaction.

VOIGT'S ELEMENTARY MECHANICS.

Elementare Mechanik als Einleitung in das Studium der theoretischen Physik. Von W. Voigt. Zweite umgearbeitete Auflage. Pp. x + 578. (Leipzig: Veit, 1901.) Price Mk. 14.

THE object of this book is to provide the student of physics with a working knowledge of theoretical mechanics. With this view the reader is introduced successively to dynamics of a particle, dynamics of rigid bodies, attractions, hydrodynamics, elasticity; in each department statics holds a subordinate position, equilibrium being treated as a particular case. The design of presenting, within the compass of a volume of moderate size, an account of the things that are fundamental in the mechanics of bodies, whether solid or fluid, rigid or deformable, is entirely laudable. It brings into prominence the essential unity of subjects which are frequently treated as independent of one another; it imposes a selection of the topics to be discussed, and thus results in the elimination of much that is artificial and conventional though sanctioned by tradition.

A critical discussion of the principles of mechanics would perhaps have been out of place in a work of this character; at any rate it is not attempted by the author. His standpoint, so far as it is indicated, would appear to be nearer to that of Thomson and Tait's "Natural Philosophy" than to that of Kirchhoff's "Vorlesungen über mathematische Physik, Mechanik." As regards methods, it is noteworthy that the author makes comparatively little use of the conception of energy, and that he does not introduce Lagrange's equations. Accordingly, the stability of floating bodies is discussed geometrically after the manner of Dupin, and the small oscillations of a system with a finite number of degrees of freedom are not discussed at all. On the other hand, space is found for an account of "vector fields" and "tensor fields." The distribution of velocity in a fluid affords an example of a vector field, the distribution of strain in a body affords an example of a tensor field; with a vector field there is associated at each point a directed linear segment, with a tensor field there is associated at each point a certain surface of the second degree. Most recent continental writings on physical mathematics treat of vector fields. The chapter devoted to the dynamics of rigid bodies is made unusually interesting by the use of the theories of several pieces of apparatus—the balance, bifilar suspension, Atwood's machine, Foucault's pendulum—as illustrations of the mode of formation and solution of equations of equilibrium or motion the theory of the application of the pendulum to the determination of the acceleration due to gravity is also given. The treatment of rolling friction, of which two accounts, apparently conflicting with each other, are given in two separate articles, leaves something to be desired. An excellent feature of the book is the emphasis laid on the "dimensions" of physical quantities; no quantity is introduced without an explicit statement of its dimensions in terms of the units of mass, length and time.

The plan and purpose of the book require that the reader should not be assumed to possess a knowledge

of the theory of partial differential equations. This restriction renders necessary some originality of method in problems relating to fluid motion and to the equilibrium and motion of elastic solids. The book should prove very useful to teachers, by showing how much of these theories can be treated adequately by the aid of simple analysis. Perhaps the most remarkable piece of work, among those designed to make the theories of mathematical physics accessible to readers whose mathematical equipment is not very large, is the discussion of the equation of transverse vibrations of a stretched string; the writer founds the theory of this equation on a geometrical method, which was initiated by Riemann in his memoir on the propagation of plane sound waves of finite amplitude. The portion of the book dealing with deformable bodies contains, among other things, a very interesting account of *stress*; the notion of stress is introduced by means of a preliminary statement in regard to the observed character of the interactions between the smallest parts of bodies. Observation seems to be credited here with proving things which must, from the nature of the case, be remote inferences from observation. The subsequent deductive investigation is very well done. Viscosity in fluids receives a good deal of attention, and the divergences between the motions and resistances of perfect and of viscous fluids are illustrated by comparing the two solutions of the problem of the steady motion of a sphere through a fluid, regarded first as perfect and then as viscous, and by the contrast between the diffusion of vorticity in a viscous fluid and the permanence of vortex motion in a perfect fluid. Although it might be wished that the treatment of the fundamental theorem of rational hydrodynamics had been less summary, yet it will be felt that the student of theoretical physics owes a debt of gratitude to Dr. Voigt for his clear outline of the theories of fluid motion.

A. E. H. L.

ESSAYS ON BIRD-LIFE.

Birds and Man. By W. H. Hudson. Pp. 317. (London: Longmans, Green and Co., 1901.) Price 6*s*. net.

THE author of "The Naturalist in La Plata" is such a close and accurate observer of nature, and has such a rich store of anecdote upon which to draw, while his style is so fresh and invigorating, that a hearty welcome from the public is well-nigh sure to await all the efforts of his pen. In this little volume he has given us a delightful series of essays dealing with bird-life in England, in the course of which he dwells specially on the relations between bird and man as they exist in nature. Many of these essays have previously appeared in various serials, but a very considerable portion of the book, including the introductory chapter, is new.

Mr. Hudson has such an enthusiastic love for bird-life that, as he tells us in this introductory chapter, the sight of stuffed birds in a museum is positively painful to him. If this be so, an obvious and easy course lies before him, and it is unnecessary on his part to say that collections of this nature "help no one, and their effect is confusing and in many ways injurious to the mind, especially to the young." No one, of course, wishes to argue that stuffed birds are as good as living ones, but since the great majority of us have neither opportunity, time, patience nor money to devote to the observation of birds in their native haunts, we may surely be permitted, if we please, to study and admire their counterfeit presentments in a museum.

Perhaps the most interesting chapter in the book is the second, which bears the same title as the book itself. Here the author tries to imagine what birds think of man. At times, he thinks, they must be considerably puzzled, as when a blackbird is petted while on its nest by the owner of a garden, only to be shot at or stoned when it leaves the protected precincts.

"Birds" (says the author) "are able sometimes to discriminate between protectors and persecutors, but seldom very well, I should imagine; they do not view the face only, but the whole form, and our frequent change of dress must make it difficult for them to distinguish those they know and trust from strangers. Even a dog is occasionally at fault when his master, last seen in black and grey suit, reappears in straw hat and flannels."

Later on it is shown how birds clearly discriminate between dangerous and harmless mammals, the author giving us many interesting anecdotes derived from his Argentine experiences of the relations between birds and mammals in the wild state.

Several of the chapters—notably the one on the Dartford warbler—are devoted entirely to British birds, but in others the author takes a wider field. Among these latter the article on geese, with its description of the vast throngs of the Magellanic and upland species to be seen at certain seasons in Argentina, is of especial interest. It closes with a pathetic anecdote of a pair of these birds, which, on account of the female having a broken wing, started to *walk* the long journey from the pampas of La Plata to distant Patagonia.

In the two concluding chapters the author gives some supplementary notes on the birds of London, and describes his impressions on first visiting Selborne in 1896. In taking leave of this charming book we have two regrets—one that it is not longer, and the other that we have not space for a fuller notice.

R. L.

OUR BOOK SHELF.

The Earth's Beginning. By Sir Robert S. Ball, LL.D., F.R.S. Pp. viii + 384. (London: Cassell and Co., Ltd., 1901.) Price 7*s*. 6*d*.

THIS is a popular account of the nebular hypothesis, based upon a course of lectures adapted to a juvenile audience, and it is, therefore, almost superfluous to remark that the subject is presented in simple language and that no great mental effort on the part of the reader is called for. The theme is one which furnishes splendid opportunities for the display of the powers of graphic description and illustration for which the author is so well known, and the book will doubtless succeed in extending the interest in this fascinating chapter of science.

From the demonstration of the existence of true nebulæ, the reader is gradually led to the evidence that the sun and earth once existed in nebulous form, and thence to see how the present conditions of the solar system accord with the hypothesis. The difficulty presented by the anomalous revolutions of the satellites of Uranus and Neptune is got over ingeniously by supposing that in these cases the concordant stage of the evolutionary pro-

cess has not yet been reached. While the application of the theory to the solar system is kept mainly in view, the evidence of its truth afforded by observations further afield is by no means neglected; but no attempt is made to trace the story of celestial evolution generally, or to state the various stellar stages through which the sun itself must have passed. Thus, for the most part, only familiar ground is traversed, and the chief value of the book as a contribution to the literature of the subject lies in the clearness of exposition and wealth of illustration.

The maintenance of the sun's heat and the principle of the conservation of moment of momentum are treated in a specially lucid manner, and the appendices dealing more fully with these questions greatly enhance the value of the book to students.

Objection might be made to the use of the term "fire mist" as applied to the original nebula, since it was not necessarily an incandescent mass, and consequently also to the extension of the theory which attributes this nebula to the collision of two dark bodies. As a minor objection, the view that the sun's photosphere is composed of particles of carbon cannot yet be regarded as the demonstrated fact which the author seems to suppose. A curious error, occurring on p. 277, may also be mentioned; it is stated that the discovery of helium in the sun in 1868 was made during an eclipse, whereas the main point of the observation to which reference is made was that it was made without an eclipse.

There are numerous excellent illustrations, many of them from photographs; but the descriptions are in some cases quite inadequate. Thus, Figs. 43, 44 and 54 will only be intelligible to those who have a fair acquaintance with astronomical spectroscopy, and the numerous photographs of nebulæ appear to have been distributed almost at random.

Monograph of the Coccidae of the British Isles. By Robert Newstead. Vol. i. Pp. xii + 220. Plates A–E, 1–34. (London: Ray Society.)

THE Coccidæ, or scale-insects, are of great importance horticulturally and economically, for although some species yield important products, such as lac and cochineal, others are among the most destructive pests of our orchards and gardens, being peculiarly injurious to plants grown under glass. Mr. Newstead, himself a practical gardener, has devoted many years to their study, and has given us the results of his painstaking investigations in the present work. He admits about ninety species and varieties of Coccidæ as occurring in the British Islands, belonging to eight of the twelve subfamilies at present recognised, the other four being at present unrepresented in Britain. The systematic part of the first volume deals only with the first subfamily, the Diaspinæ, to which Mr. Newstead refers eleven genera and thirty-seven species. A very full introduction is prefixed to the volume, dealing with the structure and habits, parasites, enemies, &c., of the Coccidæ, and practical observations on the best means of coping with their ravages, and full directions for collecting and preserving. Among the most original of the author's observations are those relating to birds as destroyers of Coccidæ.

Till recently the Coccidæ have been one of the families of insects most neglected by British entomologists, and Mr. Newstead's admirable monograph adds another to the important series of works on neglected groups of insects for which we are indebted to the Ray Society. There is still, however, much work to be done before our knowledge of the insects of the British Islands can be considered to be anything like complete, especially, perhaps, among the parasitic Hymenoptera, which have been strangely neglected by most entomologists, notwithstanding their vast number and variety, their beauty, and their economic importance in keeping down the numbers of all kinds of insect pests. This neglect may perhaps be accounted for, however, by the small size of the great majority of the species, many of which, including some of the most curious and beautiful, are among the smallest insects known. But we hope to see these and other neglected groups of insects gradually worked out, on similar lines to those followed by Mr. Newstead in the present work.

Le Sel, les Salines et les Marais Salants. Par A. Larbalétrier, Professeur a l'Ecole d'Agriculture de Grand-Jouan. Pp. 166. (Paris: Masson et Cie; Gauthier Villars. No date.)

THIS volume is one of the "Encyclopédie Scientifique des Aide-Mémoire," a title which sufficiently expresses its scope. After a brief description of chlorine, sodium and the properties of sodium chloride, the methods of production of salt from sea-water on the coast of France are described, followed by short accounts of the treatment of the mother liquors of crystallisation for bromine, of the principal European salt mines, of the production of salt from saline springs, and of the Stassfurt deposits. The book concludes with a description of the impurities and analysis of salt, statistics of production in various countries, and of the use of salt in food, agriculture and medicine, and, lastly, a bibliography—perhaps the most important part in a work which is chiefly a compilation of facts obtained from other sources.

An encyclopedic article of this description, published in a handy form, will be useful provided the data given can be relied upon. Unfortunately, in this instance this is not always the case; a number of misprints occur in the figures in the tables, misstatements are made in the chemical details, and names of places are misspelt. On the other hand, the methods of mining salt in the principal European mines and the production of salt from sea-water and saline springs in France are adequately described, and the book is written in a readable form, sufficiently illustrated and well printed.

T. S. D.

Elementary Ophthalmic Optics, including Ophthalmoscopy and Retinoscopy. By J. H. Parsons. Pp. 162. (London: J. and A. Churchill, 1901.) Price 6*s*. 6*d*.

A SOUND statement of the optical principles involved in ophthalmology, which nevertheless does not require a knowledge of higher mathematics, and which is confined within reasonable limits, has no doubt been long sought by students of this special branch of surgery, and in "Elementary Ophthalmic Optics," now under notice, they will find a trustworthy exposition of the laws affecting the refraction of the eye. The book is well printed and the diagrams are large and clear; it seems a pity, perhaps, that the author was not bold enough to depart from the conventional letters used in optical formulæ, which, such as f, f_1, f_1', f_2', become liable to confusion, though it is difficult to suggest better symbols offhand.

The student should have been warned that the equation $l_1 l_2 = F^2$ (p. 14), if applied in the case of parallel rays proceeding from infinity, becomes indeterminate. The equations proved in chapters iv. and v. become exceedingly wearisome, important though they are, but a few illustrations of their application at the time would relieve the monotony, which might frighten the more practical man from continuing his reading to the later portions of the book, where their results are made use of and where stress is laid on several most important points not usually explained or mentioned in works on ophthalmology. It is not altogether clear where all the distances given for Listing's schematic eye are measured from; also in an earlier and a later page the foci of the aphakic eye are given differently, leading to confusion in the mind of a careful reader. Chapter vii. brings into prominence some very essential facts in relation to the size of the image formed in the ametropic eye and the effect of spectacles

and their position thereon. The proofs here given should serve to elucidate some of the puzzling cases not infrequently met with in testing errors of refraction. Chapter x., again, gives much valuable information on the use of the ophthalmoscope to the best advantage, and the difficulties of retinoscopy are sufficiently dealt with in the last chapter. There is no mention of accommodation or presbyopia, several points in which might well have been touched upon. An index would have been of assistance in the search for any equation relating to a particular case.

The Process Year Book, 1901–2. Edited by William Gamble. Pp. xvi+152. (London: A. W. Penrose and Co., 1901.)

EVERY year we receive this admirable and beautiful book illustrating the present state of process work, and we cannot do better than again suggest that everyone interested in the art of picture reproduction should be the possessor of this volume. The illustrations and text still maintain their high standard of excellence, and the variety of the subjects and processes dealt with gives the reader a good insight into the manifold methods in photo-mechanical engraving and the allied arts and crafts.

It may, perhaps, be specially mentioned that in consequence of the great advance in the department of process work relating to the three-colour method the editor has introduced a variety of specimens such as perhaps never before has been collected together between the covers of a single book. A glance at these soon suffices to illustrate the high state of efficiency of the methods employed to-day; and one only wonders what the future has in store for us, since it is to this branch of process work that we look for the possibility of the greatest progress.

Nautical Astronomy. By J. H. Colvin, B.A. Pp. 127. (London: E. and F. N. Spon, Ltd., 1901.) Price 2*s*. 6*d*. net.

ONE of the greatest difficulties encountered in the study of spherical and nautical astronomy is to obtain a proper comprehension of the various circles of the celestial sphere, without which the solution of the problems involved can never be anything more than mechanical. The author of this book, however, has not thought it necessary to assist the student greatly in this direction, for fifty very brief definitions can by no means be regarded as an adequate introduction to celestial geometry. Thus, unless the student is endowed with an exceptionally good geometrical imagination, or has the advantage of a good teacher, it does not seem likely that he will be able to use the book with profit. The initial difficulties excepted, however, the book has many good features; the explanatory matter is brief and clear, and there is a useful collection of formulæ, rules, numerical illustrations and exercises to be worked out. Much space is saved by the omission of tables which do not vary, while specimen pages of the "Nautical Almanac," adapted to the exercises, have been introduced.

The book is designed to cover the elementary and advanced stages of the South Kensington syllabus, and also includes the course for "extra master" in the Board of Trade examination.

Elementary Chemical Theory. By G. H. Martin, M.A., F.C.S. Pp. 24. (London: Rivingtons, 1902). Price 9*d*.

THE only use to which this collection of didactic statements can be put is to furnish students of chemistry with material suitable for copying into their notebooks. It was scarcely worth while to attempt to extend the use of the book beyond the author's own pupils.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Cherry Disease.

IN NATURE for January 9 (p. 239) there is a report of the meeting of the Royal Microscopical Society on December 18. The president, Mr. William Carruthers, F.R.S., made a communication with respect to the cherry disease which has appeared in Kent, from which I extract the following:—

"The results of experiments in the cultivation of the fungus showed it to be one which belonged to the genus Gnomonia. Many of the fungi in this class passed through various stages in their life-history, for example the mildew on wheat, which was first developed on the berberry and then spread to the wheat, appearing first as rust and afterwards as mildew from the same mycelium. The president referred to the absence in this country of any authority competent to investigate cases such as this; on the continent, however, the Governments had taken up the matter, and the experts who had inquired into it had found that to check the spread of the disease it was necessary to collect all the dead leaves and burn them."

Prof. A. W. Bennett followed in the same strain and "enlarged upon the absence in this country of investigations into such matters by State-paid establishments, and described what was being done in the United States, where every State had its own experimental station."

Now it is not my intention to discuss whether the Government does as much for scientific inquiry in the interests of the community as it might do. But it is clear to me that nothing is gained by overstating the case. There are two "State-paid" establishments devoted to botany in this country, Kew and the Botanical Department of the British Museum. Each happens to have upon its staff an officer trained in mycological investigation. And it may be added that Mr. Carruthers is himself consulting botanist to the Royal Agricultural Society.

So far as Kew is concerned, the matter was promptly dealt with in ordinary routine. Mr. Massee, who has charge of the cryptogamic collections, had given a brief account of the disease in his "Text-book of Plant Diseases," with a figure (pp. 110, 111), although at the time (1899), so far as I am aware, the disease had not been noticed in this country. Mr. A. O. Walker, of Maidstone, sent specimens in November, 1900. I quote the *Gardeners' Chronicle* for May 23, 1901 (p. 191), where he writes:—

"Early in November I sent specimens to Mr. G. Massee, of the Kew Herbarium, who reported to me that the leaves were affected by the fungus *Gnomonia erythrostoma*, and quoted Frank's opinion that the leaves should be gathered and burnt."

The council of the Royal Agricultural Society issued on February 6, 1901, a report by Mr. Carruthers giving the history of the disease and recommending Frank's remedy of burning the leaves. There is nothing very profound in this recommendation, as it is a general method applicable to all plant diseases propagated by spores, and aims at removing the source of infection.

As I recently pointed out in NATURE (vol. lxiv. p. 212), we owe to the late Prof. Cornu "the principle now so familiar as to seem almost obvious, of preventive treatment by the careful destruction by burning of the *débris* of plants which may harbour spores."

I may add that the Gnomonia is well known to mycologists, having, in fact, been first described by Persoon as a Sphæria a century ago, and there are in the Kew Herbarium specimens of it from no less than eight published collections. Mr. Carruthers in his report, which is reproduced in the *Journal* of the Royal Horticultural Society (n.s. xxv. pp. 313–316), does not give an illustration of the Gnomonia, but figures instead a "Fragment of Leaf of Cherry Tree showing groups of Parasitic Fungi." These belong, apparently, to a species of Phoma and, so far as I am aware, there is no evidence that they have anything to do with the Gnomonia.

There the matter stands, and for my part I entirely fail to see how "the authority competent to investigate cases such as this" of whom we are said to be in want, could carry it farther. The

disease has been known on the continent for the last twenty years, and notwithstanding that "Governments had taken up the matter," we are no wiser as to the life-history of the parasite than they were in Germany at starting. Nor if we were should we be probably any better off, however interesting the result might be from a scientific point of view. For each phase of such a fungus has apparently an indefinite capacity for propagating itself independently. The rust of wheat is as destructive in Australia as anywhere else, and is not checked by being unable to complete its life-history on the barberry.

It is not material, but it may be noted that Gnomonia belongs to a group of fungi widely remote from the rust of wheat. I can hardly believe that Mr. Carruthers intended to suggest that they belonged to the same "class."

But my object in drawing attention to the matter is to remonstrate with my scientific friends for the mistaken policy which it seems to me that many of them are too apt to adopt in matters of this kind. It is the fashion now to clamour for "State-paid" assistance for everything, with no sense of the relative importance of the objects aimed at or appreciation of the work which is actually being done. It is most important that Government aid should be obtained for a definite purpose, such as that of the National Physical Laboratory. But if scientific men will not even give the Government credit for the aid it gives, they run the risk of being regarded as impossible to satisfy.

In his report, published by the Royal Agricultural and Horticultural Societies, Mr. Carruthers states :—"The neglect of undertaking this operation (burning of the dead leaves), though costly, means the disappearance of the cherry orchards of Kent in a very few years." In the face of this very serious statement it is remarkable that, so far as I can ascertain, no information on the subject has reached the Board of Agriculture.

Kew, January 22. W. T. THISELTON-DYER.

Variation in Fowls.

EVERYONE who is acquainted with poultry must join Mr. Tegetmeier in deprecating the economic degradation of good old breeds by breeding for fancy points only (p. 152). But it is an ill wind that blows nobody good, and from a scientific point of view a decadent old breed with exaggerated points is more interesting than one of the comparatively useful modern mongrels produced by crossing, since the former shows conclusively what can be done by sheer selection, even though applied for a senseless end.

Fortunately, Mr. Tegetmeier has given excellent comparative views of some breeds before and after "improvement" in his work on "Table and Market Poultry"; but if the old strains are obtainable anywhere in their primitive form it would be, I think, very desirable to get specimens and preserve them, together with some modern highly-bred birds, for the benefit of bionomical students when the declining breeds have become extinct. Meanwhile, I should like to draw the attention of students of variation to the great differences observable in domestic fowls which have not been subjected to any selection, such as the ordinary poultry of India. Among these, although they are allowed to breed anyhow, may be seen all recognised colours of fowls except those of the highly specialised laced, pencilled and spangled breeds, which have needed a long course of selection. Double or "rose" as well as single combs occur, although the latter are a minority, and small crests are common. Five toes and feathered legs are rare; the legs vary much in tint.

Now, in Egypt, I have observed that, while equally variable in coloration, the fowls displayed some structural points peculiarly their own. The combs are very often *really* double; not the coral-like "rose" comb, but a bifid or two-flapped edition of the normal compressed and serrated form. The hind toe also was very often bifid, exhibiting every gradation from the five distinct toes of the Dorking to a distally split hind toe or one in which the normal hallux was represented by a mere terminal joint with a nail, growing from the long upper supernumerary hallux. Indeed, I even got a specimen in which the extra hallux alone remained, the true first digit having disappeared altogether! The consequence was that this bird's foot looked like a curassow's, but I observed that it had very little power of grasping therewith.

In Zanzibar I again found poultry of every colour, but very true to the lanky, close-feathered, small-combed Malay or Chittagong type, which thus seems to maintain itself in spite of neglect by breeders.

What is particularly noticeable in casually-bred poultry is the correctness of some of the types of marking. Thus the silver-grey variation, in the cock, resembles the typical black-breasted red in everything except in that the red parts of the plumage are changed to white. The corresponding hen has the brown and yellow of the upper surface also replaced by white, and hence is grey in tone with a silver-streaked hackle.

When such correlated grey and rufous forms occur in wild gallinaceous birds, they are put down as climatic variations, but it is obvious that climate cannot be the *direct* cause, though it may favour the survival of one type rather than the other, according to constitution or surroundings.

Another common style of marking found in two colours is that in which the base of the neck, the primary quills and the tail are chiefly black in both sexes, the rest of the body being uniform, either white or some rufous shade ranging from bay to buff. This coloration might easily characterise a natural species, although it is not known to do so; in accepted breeds the white form has been adopted as the proper colour for the light brahma, and the cock of the golden-pencilled Hamburg breed closely approximates to the black-tailed rufous form. Hens of the black-tailed red type are, however, not recognised in any breed.

A very common and curious variation in rough-bred fowls is the "wheaten" hen. This bird is of the pale-brown colour of wheat, with a dark-brown neck and black tail; but the correlated cock is a black-breasted red of the jungle-fowl colour. This colour of the hen is recognised in Malays and old English game, and is said to breed the brightest cocks.

It has occurred to me that the occurrence of two such distinct types of hens as the "wheaten" and the "partridge" (the name given to hens of the jungle-fowl brown) in correlation with similarly coloured cocks may, perhaps, help to explain the phenomenon of dimorphism in female butterflies. For if we knew the pedigree of these insects as well as fanciers do that of their fowls we might very possibly find that in dimorphic species two strains with dissimilar females but similar males existed and interbred.

So, also, the great and sudden variations throw light on the origin of mimicry. The form of the fowl with white body and black quills and tail, above alluded to, is similar in plan of coloration to several large and powerful birds. If such a variation occurred where the form and flight were favourable to mimicry, as it might easily do among the multitudes of passerine birds, we should have mimics ready-made.

The problem in the case of butterflies is much easier, owing to their greater general similarity of shape; but in any case it is obvious that variation is more important than selection here.

Indian Museum, Calcutta. F. FINN.

Elementary School Mathematics.

THE appointment of a committee of the British Association on the teaching of elementary mathematics encourages the hope that that body will be able, after collecting the opinions of practical educators, to focus them with due wisdom into a scheme which will be generally acceptable, both to teachers and examiners. For success to be attained it is obviously necessary that those who are in actual touch with the work of teaching should state what, in their judgment, is desirable and practicable. Hoping that others besides myself will follow the example set some time ago by Mr. Hurst of Eton, I venture to write to NATURE a sketch of the conclusions to which an experience of many years at Charterhouse has led me.

I have in mind in what follows the needs of the average boy, not of that comparatively rare individual who has some real mathematical taste; but I am sure that the progress of the latter is at present often sadly retarded by the course of study through which he is put. Our public schools have, unhappily, as I think, no organisation for securing common action except the annual conference of head-masters, which has, so far, done very little for the cause of education, hence methods and ideals vary much; but I shall assume that the average character of what is taught may be gathered from the papers set in the various public examinations for which we all prepare, and from the most popular text-books in use. Taking this ground, I think the broad indictment must be at once admitted that school mathematics are altogether too abstract and

artificial; aiming at training the pure reason they have got out of touch with facts, and for many pupils degenerated into mere jugglery with symbols cast loose from thought; hence they fail to interest and influence all but a very few. Look at the questions set in any of the well-known examinations—and see how many of them consist of stock puzzles of more or less complexity, invented, apparently, solely in order that successive generations of boys may learn how to deal with them, score marks by them, and then lay them aside as useless! And, of course, a large portion of our text-books and our teaching is necessarily devoted to such questions. So long as the chief examinations maintain their present character a general reform of school mathematics is well-nigh impossible, and partial reforms at individual schools (I have Winchester in mind as a pioneer in endeavour) are very difficult. I will, however, briefly and without detail indicate directions in which I think real improvement can be made without introducing revolutionary changes.

The great aim must be to introduce as much as possible the concrete element, for there are few boys who cannot be interested keenly in what they can deal with in practical fashion by drawing or handling in any other way, and fewer still to whom a bare abstract idea is not repellent. Until elementary physical measurements and the mathematics appropriate for dealing with them are taught together, an arrangement much to be wished for both from the points of view of science and mathematics, the best field for the introduction of the concrete is undoubtedly geometry.

In all the earlier stages of geometrical work, theory should always be kept in touch with practice by much drawing and measuring of figures; this, I am convinced, is the best way of building up exact geometrical ideas, and it has besides the great advantage of being intensely interesting to boys. I do not refer to "geometrical drawing" as often taught and usually understood in examinations which aims merely at making certain constructions (though this gives a valuable bit of training to those who have too often no notion of using their hands efficiently for any purpose not connected with a ball), but I would have it used always concurrently with, and in illustration of, demonstrative geometry. This is, I know, quite possible, though I have as yet come across no text-book in which it is done.

In theoretical geometry the only serious divergences from Euclid's methods I would advocate are (1) the introduction from the first of the idea of an angle as generated by a rotation, and (2) the substitution of the arithmetical and algebraical treatment of proportion for Euclid's.

Euclid's test of proportion, which appeals so strongly to the grown mathematician by its elegance and completeness, is for even the very best boys very difficult to grasp, and for the moderate boy a rigid insistence on it (which is practically never made) would involve an absolute bar to the discussion of similar figures and elementary trigonometry, matters which are quite easy if the difficulty of incommensurability be kept in the background. I would, however, while adhering to Euclid as the only possible text-book, omit, on a first reading at least, many of the propositions in order to push on to those which connect with, and can be illustrated by, practical work. For instance, after Book I., I would have read those propositions of Book III., some dozen or so in number, proving the angle properties of circles.

Seeing that demonstrative geometry furnishes by far the most accessible example of pure deductive logic, and for most boys the only one they will ever come in contact with, I would insist most strongly on its never being sacrificed to so-called "proofs" by measurement which are found in some books. The training of the reasoning powers is one of the highest aims of education, and with this end in view constant practice in riders is of the greatest value; the teaching of Euclid's text without this is a most deadly waste of time, and cannot be too strongly condemned.

In arithmetic I think the most important reform would be the general recognition of the fact that decimals are not adapted for exact calculation, but are preeminently valuable in approximation, which is the practically useful form.

From the first, therefore, boys should be taught to work out results correct to a few places only—generally not more than four—and all work with recurring decimals should be omitted.

Many of the puzzling questions set on such subjects as discount, stocks, &c., have very slight relation to practical life, they require much time to learn to deal with them, and should be discarded in favour of work on areas and volumes of simple figures. An equal amount of thought can be elicited, and therefore a not less amount of culture imparted, by good problems on the latter subjects, with the advantage of being more in touch with practical requirements.

In algebra I would, in the earlier stages, insist much more closely than is done at present on the accurate use of symbols as a shorthand language for expressing arithmetical operations, deferring long "sums" of multiplication, division, &c., until much work has been done on simple equations of the first degree as aids to the solution of problems. Later I would omit much of the harder manipulation with fractions and abnormal index expressions which is now taught, and in place of these devote much time to the development of the notion of one quantity as a function of another, illustrated by plotting graphs on squared paper. The theory of fractional and negative indices should be taught as leading up to logarithms to base 10, but I deprecate the too early use of these in calculation.

Arithmetical trigonometry involving functions of acute angles only, and with constant reference to four-figure tables and accurate drawings to scale, should be taught much more generally than it is now. For boys in the higher forms who are but poor mathematicians I have found it an interesting and stimulating change from the weary round of arithmetic and algebra they had trodden *ad nauseam* before. A short course of the same work should, even in the case of good boys, be preliminary to the algebraical treatment of trigonometry.

I have written only of the very lowest rungs of the mathematical ladder; those who from professorial and engineering altitudes lecture us on what we ought to teach have often no notion of the mind stratum in which the greater part of our life's labour is spent; hence their advice, and their books when they condescend to write for us, are too often hopelessly above the mark. That by cooperation of all interested some real improvements in the curriculum may enable us to get a rung or two higher all round is the earnest wish of myself and many other teachers.

J. W. MARSHALL.

Charterhouse.

The Distance of Nova Persei.

SINCE publishing, in NATURE of January 2, the suggestion that the cause of the apparent expansion of the nebula surrounding Nova Persei might be explained by the illumination of meteoric matter by the light sent out on the occasion of the outburst of the Nova, I have seen a paper published by Prof. Kapteyn in the *Astr. Nach.* (No. 3756), in which he suggests the same idea. His claim to priority in the matter is therefore clear. In my note, referred to, I give the distance of the Nova as 313 light years. In calculating this distance I made the mistake of taking the date of the outburst as February 12 instead of the 22nd. This made the distance of the Nova considerably too great.

Let D denote the distance of the Nova, and r the radius of the nebula, in *miles*; and let ρ be its radius in seconds of arc. Then we have

$$\frac{r}{D}=\frac{\rho}{206265}\ \therefore\ D=206265\times\frac{r}{\rho} \quad \ldots\ldots (1)$$

But if V is the velocity of light in miles per second, and if T be the time in *days* elapsed from the outbreak of the star to the date of the photograph, then

$$r=24\times 60\times 60\ .\ V\ .\ T \quad \ldots\ldots (2)$$

Substituting this in (1) we find

$$D=24\times 60\times 60\times V\times 206265\times\frac{T}{\rho} \quad \ldots\ldots (3)$$

Also if L be the distance travelled over by light in a year of $365\frac{1}{4}$ days, *i.e.* a light year, then

$$L=24\times 60\times 60\times V\times 365\tfrac{1}{4} \quad \ldots\ldots (4)$$

Dividing (3) by (4) we find

$$\frac{D}{L}=\frac{206265}{365\cdot 25}\ \frac{T}{\rho}$$

or

$$D=\Big[\ 2\cdot 75184\ \Big]\times\frac{T}{\rho}\times L, \quad \ldots\ldots (5)$$

the figures in brackets being the logarithm of $\frac{206265}{365\cdot 25}$.

Taking $T = 211$ days from the outburst to the date of the photograph taken on September 20 and the angular distance ρ of the point (*a*) on Ritchey's photograph as equal to 480″, the distance D is equal to 248 light years. The same point on the photograph of November 13 leads to $D = 265$. The difference between these two values of D is, I believe, as Prof. Kapteyn also points out, due to the fact that the plane of the nebula is not normal to the line of sight. Ritchey also points out that, besides the radial expansion, there has been an apparent motion of the nebula round the Nova in position angle. From an examination of the photographs, the nebula seems to be evidently a spiral, and the observed shift in position angle would be caused by the gradual illumination of these spiral wreaths by the advancing spherical wave of light.

It can be shown that, if the sun were removed to the distance of the Nova, it would only be of the 10·24 magnitude, so that, even at the present moment, the Nova is more brilliant than the sun. When the Nova was at its greatest brilliancy it was about 0·2 magnitude. It must then have been 10,380 times brighter than the sun. If we take the light of the Nova at the earth as equal to a first-magnitude star and take Zöllner's estimate of this compared to the sun as $\frac{1}{5 \times 10^{10}}$, then the outer margin of the nebula with a radius of 8′ would be 430 times nearer the Nova than the earth, and would receive per unit area 430^2 times the amount of light, or $\frac{430^2}{5 \times 10^{10}}$, which is equal to $\frac{1}{270500}$, of sunlight. This is about equal to 2·2 times the light of full moon. Of course, these figures are of very uncertain value and we must not place too much reliance on them, but if we take the above value of 2·2 times moonlight as that received by the nebula, it at first seems too faint to be visible as reflected light. We must, however, recollect that the light reflected from the nebula at its brightest points cannot have an intrinsic brilliancy of more than an eighteenth-magnitude star, whereas the Nova was of the first magnitude. Hence it is only necessary for the nebula to reflect light of an intrinsic brilliancy equal to $\frac{1}{6{,}310{,}000}$th that of the Nova to seem as bright as it actually is, even assuming that the nebula has no inherent light of its own. The above figures will evidently require some alterations when the photographs available are carefully measured. W. E. WILSON.

Daramona, co. Westmeath, Ireland.

A Luminous Centipede.

IN your issue of January 9 (p. 223), an account of some observations of the Geophilus is given, from which it would appear that it used its power of emitting light as a means of protection. It might be well to point out that irritation or excitation of many luminous organisms has this result. Even in such low forms as the light-producing bacteria the same effect can be seen. In a paper on the "Physical Basis of Animal Phosphorescence," by S. Watasé, of the University of Chicago, published with the biological lectures delivered at Woods Holl, 1895, a very full account is given of the phenomenon as seen in the ordinary fire-fly, and the process is essentially the same in all light-producing organisms. In some the luminous product of cell metabolism is oxidised *in situ*, while in others it is thrown out in response to a stimulus as a liquid secretion.

J. E. BARNARD.

Birds Capturing Butterflies in Flight.

MR. LATTER still believes the capture of butterflies in flight by birds to be "exceptional so far as this country is concerned" (p. 273). Closer observation would assure him of the contrary, I think. Why is the case he mentions "probably to be regarded as a mistake on the part of the bird," when it is admitted that the captor "only relinquished its hold in consequence of a luckily-aimed stick"? Why assume that the thrower of the stick knew better what the house-martin ought to eat than the bird itself? In July 1900 I saw a house-sparrow in my garden attack a common brown butterfly on the wing (species unidentified). The chase lasted three minutes, by my watch, *in the air* the whole time, the butterfly doubling and turning again and again, and the sparrow after it, in a manner most remarkable for a bird without much hovering-power. Eventually both butterfly and sparrow went into a box hedge, and the sparrow came out immediately afterwards, eating the butterfly; he finished it with much apparent satisfaction on a branch of an apple-tree, and cleaned the scales off his beak on the twig. Sparrows are not, as a rule, insect-eaters, but J. H. Gurney gives, as a result of 694 dissections, under the heading "occasional food," these entries:—

"August.—Moth of *Crambus culmellus*."

"June.—Large brown cabbage-moth (W. Johns),"

and adds: "I have notes of sparrows occasionally feeding on the yellow Underwing, Ermine moth, and a few other insects in the perfect state. . . . Everybody must, at some time or another, have observed their clumsy efforts to catch some common butterfly" ("The House-sparrow," Gurney, Russell and Coues, pp. 11–18). These notes have the greater value because they occur in a book written with the avowed object of convicting the sparrows of a diet injurious to the agriculturist!

If, therefore, attacks by "occasional" enemies are not infrequent, why imply that the toll taken by the vast crowd of insectivorous birds "*must be* very slight?" The question is, is it? Only specially directed observations can answer this.

LILIAN J. VELEY.

Extremes of Climate in the British Empire.

I HAVE just read the note on p. 87 of your issue of November 28 last giving an abstract of the "Summary of the Climate of the British Empire" in *Symons' Meteorological Magazine*; and I think that even though it is expressly said to be only "so far as it can be represented by reports for eighteen stations," such a summary is misleading. Thus, Adelaide is given as having the highest shade temperature, absolutely ignoring the fact that Lahore, with a population 50 per cent. more than Adelaide, has a maximum shade temperature for a month or more at a time rarely falling below 116°, and often well over 120°; while in Jacobabad, a much less important place, it is true, but still a garrison town, the maximum shade temperature in June and July is more often over 120° than under it.

Again, for maximum rainfall, not to mention Cherra Punji, with an average of more than 400 inches, or many places on the west coast of India and Burmah with averages of 100 to 200 inches, the large town of Rangoon is far wetter than Calcutta. Being far from records here I can only give averages; but I do not think I am wrong when I say that the places mentioned in your paragraph are hardly typical of the extremes of climate exhibited by even the *larger* places in the British Empire, which, I take it, should be the object of such a summary.

Lalitpur, India, January 2. CHAS. A. SILBERRAD.

A GALLERY OF ANIMAL ENGRAVINGS OF THE STONE AGE.

THE clever etchings on bone and ivory of the cave-dwellers of western Europe who lived towards the close of the Palæolithic period are well known to all who interest themselves in the pre-history of man. In 1895 M. E. Rivière published the first discovery of engravings and pictographs on the sides of a cavern. The second and quite recent similar record is published in the *Comptes rendus* of the Paris Academy of Sciences (December 9, 1901, p. 1038) by MM. Capitan and Breuil. These archæologists had the good fortune to discover on the walls of the cave of Combarelles, in the neighbourhood of Eyzies (Dordogne), 109 engraved figures which date from the Magdalenian epoch. All the figures are engraved upon the vertical walls of the cave for a distance of 100 metres on each side of the passage. They reach to an average height of 1·50 metres, commencing at about 15 or 20 centimetres above the ground and often extending to the roof—which, in truth, is mostly low, being only one to two metres in height, but this has been curtailed by stalagmites.

The figures are mostly deeply graven in the rock, but some designs are merely scratched. Very often they have been coated by a layer of stalagmite which is

sufficiently thick in some places to more or less completely obliterate the figures. In some figures the incisions have been reinforced by black pigment, which occasionally replaces the cuts. Sometimes, more especially about the head of certain animals, the surface of the rock is scraped away around the contour of the figure so as to throw it into a slight relief.

The style of the engravings is in complete accord with those etchings on bone and antler which occur in the Magdalenian stations, and their character proves that

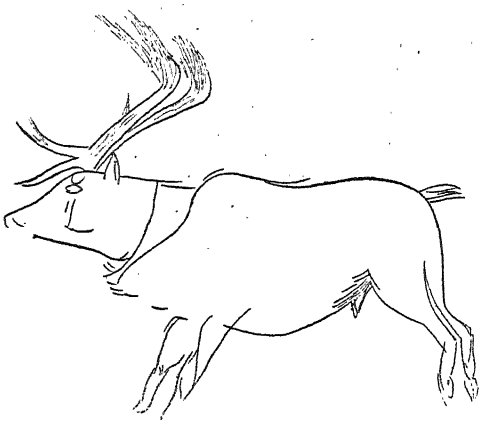

FIG. 1.—Running Reindeer, Cave of Combarelles.

they were drawn by artists who were perfectly familiar with the living animals. As in the earlier finds, the animals may be represented separately, or intermingled, or in definite groups.

Among the forty representatives of horse-like animals, at least two distinct types are recognisable. One has a massive head with a convex nose, the mane is short and stiff or long and flowing, and the tail is similar to that of our own horses. Some of these horses were domesticated; several very clearly show a halter and others a cord round the

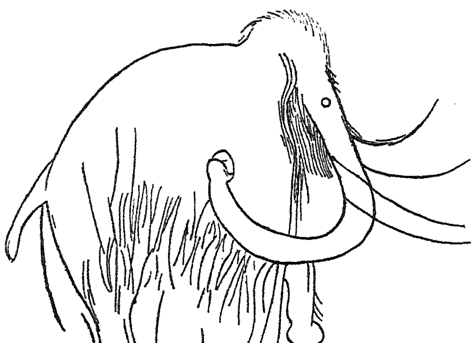

FIG. 2.—Mammoth, Cave of Combarelles.

muzzle; a covering of some sort appears to be thrown over the back of two of the horses. This new evidence, in addition to the several representations of haltered horses from the cave of Mas d'Azil, seems to prove beyond question that the horse was domesticated at this early period. Certain Equidæ are represented of a more elegant shape, with a small head, slender legs, short and always erect mane, and with a tail that arises low down and is bare save for a terminal tuft of long hair.

The representations of the Bovidæ are less frequent. Three appear to represent bisons; one is not unlike the domestic cattle of to-day; a third, with erect mane, slightly incurved horns and a dewlap provided with long and abundant hair, recalls certain African antelopes. Two heads may be attributed to the saiga antelope, and one large head suggests that of an eland, but it is without horns. There are only two entire figures of reindeer; the one which is represented as running is here reproduced. The artists have clearly indicated the differences between the reindeer and the wild deer of Europe, of which there are three examples.

The drawings of the mammoth are of interest second only to that of the horses. Of the fourteen examples, some are represented as entirely covered with hair and look like fluffy balls; others have less hair, but are provided with a fleece on the under side of the body, on the head and occasionally around the mouth, as shown in our illustration. The trunk, the tusks, which are always strongly recurved, and the great characteristic feet are very distinctly drawn; only in two figures are indicated the details of the form of the ears.

The only approach to a representation of a human face is a kind of irregular circle with an indication of two eyes and some marks for the nose and mouth. Among other simple signs were three roof-like fairly complicated designs, a double-contoured lozenge in the middle of the body of a horse, several M-like marks, semicircles, &c., which may be related to the script-like paintings found in the Mas d'Azil cave, and, finally, a group of very distinct small cups.

As only a preliminary paper has been published by the French savants, we are unable to give any further particulars of this most interesting and important find. The publication of all the particulars will be eagerly awaited by archæologists, as doubtless fresh light will be thrown upon these very remarkable troglodyte artists, who

"Pictured the mountainous mammoth, hairy, abhorrent, alone—
Out of the love that he bore them, scribing them clearly on bone."

A. C. H.

THE UNIVERSITY OF LONDON.

THE Drapers' Company has come forward with a generous offer in order to secure the incorporation of University College with the University of London. The offer is contained in the following resolution, which was brought before the Senate of the University on January 22:—"That the Drapers' Company, believing that it is for the good of the higher education in London that University College should be incorporated in the University of London, and that for this purpose it is desirable to place the site, land, buildings and endowments of the college at the complete disposal of the University, are willing to facilitate this object by making themselves responsible for the debt on University College to the extent of 30,000*l*., provided that the Senate of the University and the corporation of University College can, before February 28, 1903, agree upon a scheme for the incorporation of the college in the University, and such scheme be approved by the company."

At first sight it seems difficult to imagine how such an incorporation can be effected. Committees appointed by the University and University College will consider the matter, and it is to be hoped that the bearings of the proposal will soon be published. An additional inducement for the realisation of this scheme lies in the announcement made by Sir Michael Foster that a gentleman is prepared to give to University College 1000*l*. a year, redeemable either by himself or his executors by payment

of 30,000*l*. free (in the latter case) of legacy duty, on condition that the college becomes incorporated in the University on terms similar to those on which the gift of the Drapers' Company has been made, and satisfactory to Sir Michael Foster and two other persons to be named hereafter.

The Senate of the University has decided to devote the grant of 10,000*l*. by the London Technical Education Board to the following objects, subject to the approval of the Board and to the result of negotiations with the various institutions interested :—

(1) To found two professorships and two assistantships in chemistry ; (2) to organise the teaching of German in London by appointing two professors and three readers. The classes will be held at the colleges and polytechnics, but the fees will be paid into a central fund, and the whole staff will be under the direction of the University ; (3) to make grants of 1425*l*. and 1000*l*. a year respectively to two institutions in aid of the faculty of engineering ; (4) to appoint and pay the regular staff of teachers in the London School of Economics ; (5) to reserve 800*l*. a year pending negotiations with the London County Council as to the establishment of a day training college.

A scheme for establishing advanced courses of study on physiology in the University buildings has been approved by the Senate, and 400*l*. has been voted to meet the donation of 2000*l*. by Mr. Walter Palmer.

From the *British Medical Journal* we learn that each course will consist of not less than eight lectures, or will extend over at least eight weeks, and attendance will be open without fee to students of the University and to other persons approved by the principal. It is recognised to be essential to the success of such lectures that they should immediately proceed from laboratory work, and be in a large measure demonstrative of current research. It is, therefore, necessary that the University lecture-room should be supplied by preparations and work-rooms in which current research will be actually prosecuted. It is hoped that from the outset the University lecturers and other physiologists may be able to prosecute research in these accessory rooms, and it is strongly felt that official recognition and provision for research is in several ways essential to success, first, as a corrective of a purely verbal and didactic type of lecture, and secondly, as being calculated to stimulate the intellectual interest of University lecturers and other students. Further, the working of the scheme will afford at a relatively small cost evidence on the point whether a larger scheme for the establishment of a central institute of physiology and experimental psychology will be practicable in the future.

It is proposed that the list of annual courses of lectures shall be prepared and advertised during the preceding year, and candidates for the honours school in physiology will be permitted to nominate any two subjects on the published list for the special practical examination. The provisional arrangements are as follows :—

The first course, to begin in May, will be given by Dr. Leonard Hill, F.R.S., on the circulation. Dr. A. D. Waller, F.R.S., will give a double course, on (*a*) signs of life, (*b*) animal electricity. Prof. E. H. Starling, F.R.S., will begin a course, on the sources of animal energies, in October, and Dr. M. S. Pembrey a double course on (*a*) heat, (*b*) respiration.

The arrangements for 1903 are provisionally as follows :—January, Prof. W. D. Halliburton, F.R.S., on proteids, and Prof. W. M. MacDougall, on sense organs ; May, Dr. G. A. Buckmaster, on the blood ; and Prof. J. Bretland Farmer, F.R.S., on vegetable cytology ; in October, Dr. F. W. Mott, F.R.S., on the central nervous system, and Prof. W. R. Dunstan, F.R.S., on a subject not yet announced.

NOTES.

THE determination of the fundamental unit of electrical resistance by the late Principal Viriamu Jones ranks among the most important of such determinations, and justly acquired for him a foremost position among physicists. This determination was carried out by means of a modification of the Lorenz method, and a machine for the purpose, on which he spent 400*l*., was erected by Principal Jones at the University College at Cardiff. He was, however, of opinion that improvement was possible, and accordingly the Drapers' Company, in 1898, in recognition of his signal services both to science and to education, voted to him the sum of 700*l*. for the construction of more perfect apparatus. This apparatus he proposed ultimately to set up at the National Physical Laboratory, where preparation had been made to receive it. His illness and death prevented the realisation of these hopes, but the Drapers' Company have, with great generosity, and with a view of showing their appreciation of his merits, confirmed their vote and announced their intention of putting the sum of 700*l*. at the disposal of the committee of the Laboratory for the complete equipment of a Lorenz apparatus as a memorial to Principal Jones. The apparatus is to be erected under the supervision of Prof. Ayrton, F.R.S., and the director. This valuable gift has been accepted by the committee of the Laboratory; a tablet will be affixed to the apparatus stating that it was presented by the Drapers' Company in memory of Principal Viriamu Jones and in recognition of his great scientific attainments.

THE annual meeting of the Institution of Naval Architects will be held on Wednesday, March 19, and the two following days. The Earl of Glasgow, president, will occupy the chair. On behalf of the members of the Institution, the council has accepted an invitation to take part in the summer meeting of the Schiffbau Technische Gesellschaft, which is to be held in Düsseldorf on June 2. There will be no regular summer meeting of the Institution this year.

WE much regret to see the announcement of the death of Mr. A. W. Bennett, lecturer on botany at St. Thomas's Hospital, and the author of a number of books and papers on botanical subjects. Mr. Bennett was for several years the sub-editor of NATURE, and was an occasional contributor to these columns up to the time of his death, on January 23. He was sixty-eight years of age.

A MEMORIAL tablet is about to be placed in Harpenden Parish Church bearing the following inscription :—"In affectionate memory of Sir John Bennet Lawes, Bart., F.R.S., born at Rothamsted, December 28, 1814, died at Rothamsted, August 31, 1900. He used his long life and his great knowledge and experience as an agricultural chemist, and as a practical and scientific farmer, in the pursuit of truth, and for the benefit of his fellow men in his own country and in all parts of the world. This tablet is erected by the parishioners of Harpenden and others who deeply feel his loss as an example and friend."

THE Wellington correspondent of the *Times* states that at a public dinner given to the officers and men of the *Discovery* by the Philosophical Institute of Canterbury and the citizens of Christchurch, a number of interesting speeches were made. Captain Scott, who was loudly cheered, replying to the toast of "The *Discovery* Antarctic Expedition," said it was their intention to pass down the 175th meridian a little to the eastward of New Zealand. Then they hoped to pass down the east coast of Victoria Land, leaving records of what they had done. These records could be picked up by any relief expedition that might follow them. Next they would go to the south of

Victoria Land through those regions which Sir Thomas Ross discovered in 1840, and which they hoped to explore. They also hoped to pass along the ice barrier that stretched for 300 or 400 miles to the eastward. Then they would pass into the region of the unknown. When they returned to New Zealand, probably in two years' time, they might come back as beggars, for, though they had provisions and outfit for a three-years' cruise, wages and other things had been arranged for two years only.

THE following official statement of the plans of the Carnegie Institution (see p 278) is given in *Science*:—"It is proposed to found in the city of Washington, in the spirit of Washington, an institution which, with the cooperation of institutions now or hereafter established, there or elsewhere, shall, in the broadest and most liberal manner, encourage investigation, research and discovery, encourage the application of knowledge to the improvement of mankind; provide such buildings, laboratories, books and apparatus as may be needed, and afford instruction of an advanced character to students whenever and wherever found, inside or outside of schools, properly qualified to profit thereby. Among its aims are these: (1) To increase the efficiency of the universities and other institutions of learning throughout the country, by utilising and adding to their existing facilities, and by aiding teachers in the various institutions for experimental and other work, in these institutions as far as may be advisable. (2) To discover the exceptiona man in every department of study, whenever and wherever found, and enable him by financial aid to make the work for which he seems specially designed, his life work. (3) To promote original research, paying great attention thereto, as being one of the chief purposes of this institution. (4) To increase facilities for higher education. (5) To enable such students as may find Washington the best point for their special studies to avail themselves of such advantages as may be open to them in the museums, libraries, laboratories, observatory, meteorological, piscicultural and forestry schools and kindred institutions of the several departments of the Government. (6) To ensure the prompt publication and distribution of the results of scientific investigation, a field considered to be highly important. These and kindred objects may be attained by providing the necessary apparatus, by employing able teachers from various institutions in Washington and elsewhere, and by enabling men fitted for special work to devote themselves to it, through salaried fellowships or scholarships, or through salaries, with or without pensions in old age, or through aid in other forms to such men as continue their special work at seats of learning throughout the world."

ALL the international balloon ascents which took place in Europe on the morning of December 5, 1901, were made in an extensive area of high barometric pressure, the centre of which lay over Germany. Two recording balloons were sent up from Trappes (near Paris); one reached 14,380 m., lowest temperature $-72^{\circ}\cdot9$ C. (on ground -1°); the other reached 14,900 m., lowest temperature $-75^{\circ}\cdot8$ (on ground -3°). The Strassburg balloon rose to 6580 m., minimum temperature $-30^{\circ}\cdot5$ (on ground -2°). From Berlin two recording balloons were sent up; at 7634 m. $-38^{\circ}\cdot7$ was registered (on ground $-5^{\circ}\cdot4$); at 9606 m. $-52^{\circ}\cdot8$ was recorded (on ground -4°). Two manned balloons also ascended. From Vienna -40° was recorded at 6920 m. (on ground 1°). A manned balloon was also sent up. From Pavlovsk (near St. Petersburg) the greatest height attained was 3120 m., minimum temperature $-14^{\circ}\cdot7$ (on ground -11°). Mr. Rotch also sent up kites from Blue Hill Observatory in the afternoon. Temperatures of $-9^{\circ}\cdot9$ at 1343 m. and -9° at 800 m. were recorded. The kites remained up for two hours.

THE current number of the *Nineteenth Century* contains an instructive article on "The Reduction of Town Fogs," by the Hon. Rollo Russell. The author, who has for many years made a special study of the subject, divides fogs, so far as London is concerned, into four classes:—(1) Damp fog or mist with much cloud, from the ground up to about 1000 feet. Dust particles not numerous, and town clearer than country. (2) Damp fog or mist, dense in country. This type may be slight in London, especially if the fall of temperature has not been great. In mid-winter the fog tends to increase during the day-time in town, while in the country it rapidly dissolves. (3) Dense dry fog, with low temperature following a very cold night. It is anticyclonic in character, and the lowest strata of air are much colder than the strata at 500 to 1000 feet. Fogs of this kind are the most serious and most frequent in London; their approach can usually be foretold. (4) Occasionally a fog occurs after a severe frost, when a warm southerly wind displaces the cold air near the surface. This fog is most dangerous to traffic, being the densest. It is the least damaging to health, and may not reach more than 50 feet above the ground. The author considers that the need of the day is not so much scientific inquiry as administrative regulation, by which dark fogs might be reduced to almost harmless proportions. The preparation of forecasts is useful, as in the case of storms. Observations of the upper clouds are especially valuable in the prediction of fogs, but in London these clouds cannot always be seen; in such cases valuable data could be obtained by sending up a small balloon, with recording thermometer and hygrometer.

THE Meteorological Office pilot chart of the North Atlantic and Mediterranean for the month of February shows that very little ice was reported in the neighbourhood of Newfoundland during December, the latest date being the 11th, when a berg was seen not far from Cape Race. The Belle Isle route being closed for the winter, there were no reports from that region. Northward of Iceland unusually heavy ice has been seen. With regard to the paths of cyclonic disturbances, it is pointed out that on the eastern side of the Atlantic storm centres may be fallen in with, not only near the Azores, but even southward of the latitude of the Canaries. These, however, are much more erratic in their movements than those of the more northern ones, so that at times the changes of wind and barometer seem to be subject to no rule. On the western side of the ocean there are areas where the gale frequency this month is from 25 to nearly 40 per cent. of the wind records, the February storms being amongst the most violent and disastrous experienced in the course of the year, the exceptionally severe weather of February, 1899, being referred to as an illustration. This is the period of least fog about the banks of Newfoundland, the area of slightly more than 10 per cent. frequency being limited to a narrow strip across the southern extremity. The "smokes" of the Bight of Benin are mentioned, and it is stated as an unusual occurrence that a very dense fog visited Abaco Island, Bahamas, in February, 1901, dwellings being invisible at a distance of 100 feet. The remarks on currents deal with Rennel's Bay of Biscay current and the variations in the velocity of the Gulf Stream according to the time of day and of the lunar month, the daily maximum variation of strength being nearly 2 knots an hour and the mean daily variation about $1\frac{1}{2}$ knots. In heavy gales on the coast of North Carolina strong local currents are set up which completely mask the tidal streams. Two inset charts illustrate the easterly and northerly types of weather over western Europe at this season, and the paths of Mediterranean disturbances are dealt with.

SOME years ago Prof. J. W. Moll made experiments on the effect of forcing water into cut stems; this was managed by tying the shoot into the short arm of a U tube, containing water, and

pouring mercury into the long arm. The method is still used for demonstration purposes, but it has certain disadvantages. One of these—namely, the fact that the pressure diminishes as the water passes into the plant—the author now proposes to remove by the use of the apparatus described in a paper on the hydrosimeter (Amsterdam Academy of Sciences, vol. iv., November 1901). The arrangement by which this is effected is simple and practical, and may no doubt be useful in other cases where it is desired to subject a plant to prolonged and constant pressure. The paper is illustrated by a drawing of the apparatus, and has the merit of being written in English.

LIGHT electric motor carriages, or "runabouts" as the Americans have termed this type of vehicle, were a feature of the recent exhibition of automobiles held in New York. According to the *Electrical World and Engineer*, the Electrical Vehicle Co. of New York was represented by a light car of this type weighing only 394 kg. and provided with a battery of the new Exide cell, capable of driving the carriage 64 km. at a speed of 22 km. per hour. The American Bicycle Co. exhibited an electrical carriage weighing 450 kg. The battery in this case was composed of thirty cells, and was of sufficient power to drive the vehicle for four hours at the rate of 27 km. per hour. The Baker Motor Vehicle Co. showed a light "Stanhope" weighing 405 kg., provided with a battery of ten Planté cells, capable of driving the carriage 64 km. on one charge. The battery weighed 140 kg. It would have been interesting to know the average life of the plates in these batteries under normal road and running conditions, but upon this crucial point nothing is said in the report before us. In large towns, where several generating stations exist, and where the recharging of exhausted batteries is a comparatively simple affair, we believe there is a useful future before this type of motor-vehicle.

PROF. P. ZEEMAN, in a paper recently read before the Amsterdam Academy of Sciences, (November 30, 1901), stated that he had been investigating the limits of resolving power attainable by means of the Michelson Echelon grating spectroscope, with an instrument consisting of thirty plates, each 7·8 mm. thick, set at steps of 1 mm. Testing by means of light sources in magnetic fields of gradually increasing intensities, he found that the resolving power was almost equal to its theoretical value.

IN a paper on the energy of the universe in the *Revue scientifique*, M. I. Skvortzow discusses the influence of electrical phenomena in cosmogony. He considers that in the past history of the earth, and of other celestial bodies, electrical and chemical energy have originally played the most important part, and that heat energy has become more and more important in proportion as the earth has assumed a more material form, so that the more its energy has passed from the dynamic to the static form the greater has been the absorption of dynamical energy in overcoming resistances. The heat of the earth M. Skvortzow attributes to electric currents circulating mostly near the surface; the interior of the earth, on the other hand, he thinks may be as cold as the greatest depths of the ocean. Changes in the aspect of the earth, as well as meteorological phenomena, are attributed to electric currents induced by solar influence. The temperatures of different planets are considered to depend less on their distance from the sun than on their reserve of energy and on the currents which the sun induces in them in virtue of their axial and orbital motions. Will this theory of the electromagnetic origin of the earth's heat reconcile the two opposing views on the age of the earth?

THE somewhat heated controversy which ensued at the beginning of last year on the occasion of the starting of the London United Tramway's electrical system has borne after-fruit in the paper on earth currents derived from distributing systems which was read last Thursday before the Institution of Electrical Engineers by Mr. E. B. Wedmore. The author treated the subject of the magnetic disturbance caused by the currents leaking from the rails of a rail-return tramway system from a mathematical and practical point of view, and also discussed briefly the electrolytic troubles that may arise. To judge by the paper itself and the discussion, which was of a very quiet nature, the whole subject is in need of further investigation. This applies, perhaps, more particularly to the question of the electrolysis of gas and water pipes. With most of the speakers it seemed to be an article of faith that the leakage currents under Board of Trade rules will not do any damage worth considering, but experimental evidence, which is doubtless very difficult to procure, is wanting. There still remains to be explained the presence of the fifteen amperes which were found flowing in the London United Tramways' rails before the system had started electrical working, and it is not to be wondered at if facts such as these make gas and water engineers feel uncomfortable. Another point brought out by two speakers is worthy of notice; the term earth currents has for long definitely meant the cosmic phenomena, and should not be applied to the leakage currents from tramways, or else confusion is sure to result.

THE Dumoulin process for the electro-deposition of copper in the form of tubes does not appear to have been very successful at Widnes, where a works for operation of this process was built in 1896–1897. According to the fifth annual report of the Electrical Copper Co., it has been decided to close the works permanently and to sell the plant, since at no period of its operation has a profit been earned. This failure to earn profits is ascribed, to the small output—only thirty tons per month, to the high price of fuel, and to the heavy interest charged on the loans raised by the company. The directors in their last report, however, still speak confidently of the value of their patents (which stand in their balance-sheet at 405,000*l.*), and negotiations are to be opened for the sale of these to refiners able to work the process on a larger scale of operations. We may remind our readers that the Dumoulin process depends upon the electro-deposition of copper upon revolving mandrils; specially treated strips of skin being used to supply the friction necessary for obtaining smooth and dense deposits. The process differs from the well-known Elmore process chiefly in this substitution of skin for agate burnishers; and it is noteworthy that in neither case has the financial success realised the early expectations of the promoters of the companies operating these processes.

A REPORT on the Rampur coal-field, which lies in the Central Provinces of India, north-west of Sambalpur, has been prepared by Mr. G. F. Reader (*Mem.* Geol. Survey, India, vol. xxxii. part ii.). A good steam coal, 7 feet 10 inches thick, and two other seams of workable coal, have been proved to exist. Their extension has, however, to be determined.

WE have received from Mr. A. Gibb Maitland, Government Geologist, the annual progress report for 1900 of the Geological Survey of Western Australia. A detailed geological map of Kalgoorlie has been prepared and will be published together with a full report on the geology of this important mining centre. The lodes are for the most part bands of basic rocks, which are characterised by strong foliation, by the alteration of amphibole into chlorite and carbonates of iron, lime, manganese and magnesia, and, finally, by the development of secondary silica, mica, pyrites, gold, tellurides of gold, &c. There are no grounds for believing that the mines of Kalgoorlie have reached the limit of ore deposition, or that the lodes will not prove productive in depth. Reports on other

metal-mining districts have been made; attention has been given to the possible extension of artesian water-bearing strata, and also to borings in search of coal near Albany, where in all cases the floor of older crystalline rocks was reached without evidence of coal-bearing strata.

FROM the Iowa Geological Survey, which is under the direction of Dr. Samuel Calvin, State Geologist, we have received the eleventh volume, comprising the annual report and accompanying papers for 1900. The papers are brief memoirs on seven counties, in which the geology is described, typical sections are noted in detail, fossils are recorded, particulars are given of economic deposits and soils, and the papers are admirably illustrated. The Survey is carried on with evident vigour and ability. Special reports on coal, artesian wells, lead and zinc ores have already appeared. Dr. S. W. Beyer, one of the special assistants, has now in preparation a monograph on Iowa clays, and others are working at the materials suitable for the manufacture of Portland cement. We are informed by Dr. Calvin that the demand for the publications of the Survey has, so far as the earlier volumes are concerned, exceeded the supply. Yet much ignorance prevails, and samples of yellow mica or iron pyrites are received almost weekly from persons who imagine they have discovered gold in Iowa; and an important part of the survey work is to prevent useless explorations for geological products.

THE *American Naturalist* commences the year well, some of the articles in the January number being of more than usual interest. Among them is one by Dr. R. W. Shufeldt, on the habits of kangaroo-rats in captivity, illustrated by a couple of excellent photographs of these curious little American rodents, taken by the author from life. The specimens, three in number, which Dr. Shufeldt had under observation belonged to the species known as *Perodipus richardsoni*, and became quite tame after a few days in confinement. "They hopped about," he writes, "with great agility on their hind pair of kangaroo-like legs, while the little short pair of anterior limbs were curled inwards on the chest. . . . They are able climbers, and the rapidity with which they can dig a burrow in ordinary ground is astonishing. They use the fore-feet to perform the digging part and the long and strong hind-legs to kick the loosened soil out of their way behind, as it accumulates every moment or so. In soft soil one of these little mammals can put itself out of sight in less than a minute by digging." It is added that kangaroo-rats are in the habit of turning their cheek-pouches inside out in order to clean them. In another article in the same journal, on the best method of mounting fishes for museum-exhibition, Mr. S. E. Meek pronounces in favour of quadrangular glass-vessels, in which the specimens, after being painted on the side to be shown with water-colours, are placed in alcohol as if swimming. It is added, however, that this method, although the best yet devised, is by no means perfect, and discussion is invited from experts in the hope that a more satisfactory way of exhibiting these animals may be devised.

A POPULAR account of the principles and performances of telegraphy without intervening wires is given by Mr. S. R. Bottone in his little book on "Wireless Telegraphy and Hertzian Waves," the second edition of which has been published by Messrs. Whittaker and Co. The first edition was noticed in NATURE of September 27, 1900 (vol. lxii. p. 522).

IN the letter on the influence of temperature on the action of nitric acid on metals, which appeared in NATURE of December 12, 1901, the words "the temperature abruptly rising from 80° C. to as much as 104° C." were printed as received from Dr. A. J. Ewart, who, however, now informs us that they should read "the temperature abruptly rising *to* from 80° C. to as much as 104° C."

A SECOND edition, revised and extended, of Dr. S. Rideal's work on "Water and its Purification" has been published by Messrs. Crosby Lockwood and Son. The original edition was reviewed in these pages on April 29, 1897 (vol. lv. p. 602), and the book remains substantially the same, though changes have been made in the chapter on the characters of natural waters, and there are several additions dealing with recent water epidemics and with sand filtration. It is a little surprising to find in a scientific book that the employment of a dowser or "water-finder" is suggested, and the cautious remark is made with reference to water-finding that "if further research should discover a physical law underlying the process, its utility would become more certain and extended." The same remark could just as reasonably be made of astrology, chiromancy, or any other process of divination.

A CATALOGUE of protected rheostats, measuring instruments and electrical apparatus relating to them has been issued by Messrs. Isenthal and Co. The rheostats have been devised to economise space on switchboards and elsewhere and to minimise the chances of short circuit. In the Electra Rheostats (Schindler-Jenny's patents) the resistance wires are embedded in a highly refractory, insulating material, and a protecting sheet of metal is cast around the latter. Instruments constructed upon this plan do not possess the defects commonly found in other embedded rheostats, and they are particularly suitable as motor-starting rheostats for continuous and rotary current. The Dimmer switches, also included in Messrs. Isenthal's list, provide a means of moderating the light of electric incandescent lamps. By means of a reducing rheostat in the switch the light of an electric lamp connected with it may be given four degrees of brightness, from the dimness of a night light to full luminosity. The measuring instruments include several types of voltmeters, ampèremeters, and cell testers, for workshop and laboratory use.

THE twenty-third communication from the laboratory of van 't Hoff to the Prussian Academy of Sciences, on the conditions of formation of the oceanic salt deposits, contains a summary of the results obtained from the investigation of solutions saturated at 25° C. with sodium chloride and containing the chlorides and sulphates of magnesium and potassium. As the result of this series of researches, the conditions of existence of a large number of the Stassfurt salts in contact with aqueous solutions, and inversely the conditions necessary for the separation of these salts from the mother liquors, have been accurately established. The salts or minerals for which these valuable data have been obtained are—bischofite, sylvine, thenardite, carnallite, glaserite, astrakanite, reichardtite, kieserite, schönite, leonite and kainite, all of which may separate from solutions at 25° C. The two salts langbeinite and löweite are apparently not capable of existence in contact with solutions at this temperature, and their occurrence in the Stassfurt layers points to the prevalence of a higher temperature than 25° C. in the formation of these natural deposits.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus*) from India, presented by Mr. C. Hunterbrocken; a Patas Monkey (*Cercopithecus patas*) from West Africa, presented by Mr. A. Richmond; two Sharpe's Wood Owl (*Syrnium nuchale*), a White-throated Monitor (*Varanus albigularis*) from West Africa, presented by Mr. William Cross; a Bengalese cat (*Felis bengalensis*) from the East Indies, two Egyptian Geese (*Chenalopex aegyptiacus*) from Africa, an Anaconda (*Eunectes murinus*) from South America, a Black Sternothere (*Sternothaerus niger*) from West Africa, deposited; a Barasingha Deer (*Cervus duvaucelli*) from the Himalayas, received in exchange.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN FEBRUARY.

Feb. 1. 19h. 10m. to 20h. 29m. Moon occults β^2 Scorpii (mag. 5·2).
1. 19h. 10m. to 20h. 28m. Moon occults β^1 Scorpii (mag. 3·0).
3. 0h. Mercury at greatest elongation (18° 17′ E.).
6. 17h. Jupiter in conjunction with moon. Jupiter 5° 26′ S.
8. 17h. Venus in conjunction with moon. Venus 3° 9′ N.
9. 9h. Mercury in conjunction with moon. Mercury 2° 23′ S.
12. 7h. 40m. to 8h. 18m. Moon occults ϵ Piscium (mag. 4·5).

VARIABILITY OF THE SATELLITES OF SATURN.—In the *Bulletin de la Société Astronomique de France* (January 1902), M. L. Rudaux directs attention to the probable variation in the brightness of the satellites Titan and Japetus, from evidence furnished by observations since 1892. He concludes that in the case of Titan the change is about half a magnitude, from 8·0 to 8·5, and, moreover, the variation appears to occur regularly at the same parts of the satellite's orbit. Maxima occur near and just after west elongation, and minima when the satellite is between superior conjunction and east elongation. A suggested explanation supposes the existence of fixed regions of different brightness and the rotation period equal to the time of revolution, as in the case of our own moon. There is a rapid passage from maximum to minimum.

The satellite Japetus is also thought to have equal periods for rotation and revolution, and the observation of Cassini is confirmed that the body almost becomes invisible in the eastern portion of its orbit. The variation is from the ninth to twelfth magnitude.

Prof. T. J. J. See refers to the variable visibility of Japetus in an article giving measures of the diameters of the satellites of Jupiter and Saturn in *Astronomische Nachrichten* (Bd. 157, No. 3764). He says, "The disc of Titan is rather obscure, but that of Japetus is even more so; in fact, only one side gives sufficient light to enable the observer to recognise a disc. This is visible when the satellite precedes the planet."

MAGNETIC OBSERVATIONS DURING TOTAL SOLAR ECLIPSE, MAY 18, 1901.—In a pamphlet reprinted from the *Overgedrukt uit het Natuurkundig Tijdschrift voor Ned-Indië* (vol. lxi., part iii. pp. 173–193), Dr. W. van Bemmelen presents the observations undertaken at Batavia and Karang Sago (Sumatra) during the last total eclipse of the sun on May 18, 1901. The determinations were made on behalf of the Batavia Observatory in response to the appeal of Dr. L. A. Bauer for accurate measures. The observations were made both visually and by means of self-recording photographic apparatus, reproductions from these latter being given. Although complicated by the presence of various common disturbances, the curves show decided irregularities about the time of eclipse which are thought to be due to the occurrence of that phenomenon. The observations at Batavia were only rendered possible by the courtesy of the Electric Car Company in stopping traffic over their lines from 11.30 a.m. to 2.30 p.m. on the day of eclipse.

SIMULTANEOUS VISIBILITY OF SUN AND TOTAL LUNAR ECLIPSE.—In the *Transactions* of the Vienna Academy of Sciences (Section of Mathematics and Natural Sciences) No. xxiv. pp. 263–271, Herr Dr. C. Hillebrand directs attention to the possible observation of both sun and total lunar eclipse at such times when the phenomenon occurs as the moon is rising or setting. As the refraction at the horizon is greater than the diameter of the lunar or solar disc, the sun will be visible after true sunset or before true sunrise; the conditions for the eclipsed moon to be thus seen may be fulfilled at certain localities during the lunar eclipses of April 22 and October 16 of the present year.

THE VALIDITY OF THE IONISATION THEORY.[1]

Introduction.—The theory of electrolytic dissociation as advanced by Arrhenius in 1887 is based primarily upon the facts that the molecular conductivity of solutions increases with the dilution, that substances which, when dissolved, conduct electricity also have abnormally low molecular weights in such solutions when tested by osmotic or freezing- or boiling-point methods, and that the so-called degree of dissociation may be calculated from the electrical conductivity or the results of the molecular weight determinations. In his original article, Arrhenius states that the phenomena of electrolysis, when viewed from the standpoint of thermodynamics, require the assumption of free ions, as was pointed out by Clausius, and that the well-known additive properties of solutions support this hypothesis. Arrhenius sought to save van 't Hoff's theory of solutions from having but a limited application, and to extend it.

Van 't Hoff found it necessary to introduce the factor i in the case of electrolytic aqueous solutions in order to make them conform to the gas equation. This factor Arrhenius calculated from the electrical conductivity on the one hand and from molecular weight determinations on the other, the resulting figures showing an agreement to within 5 to 15 per cent. The agreement was not good, and the results were obtained exclusively from aqueous solutions. The non-aqueous solutions then known were practically non-conductors, and appeared to be fairly normal as regards van 't Hoff's theory, so that non-aqueous solutions in general came to be regarded as having normal molecular weights and as being non-conductors.

Behaviour of Non-aqueous Electrolytic Solutions.—Previous work has already shown that non-aqueous electrolytic solutions are frequently abnormal in the light of the ionisation theory. Thus in many cases the molecular conductivity decreases with increased dilution, *e.g.* NaI and NaBr in benzonitrile, $AgNO_3$ in piperidine, $FeCl_3$ in pyridine and in benzaldehyde, and CoI_2 in $POCl_3$. In other cases the molecular conductivity at first increases and then decreases with dilution, *e.g.* $FeCl_3$ in paraldehyde, CBr_3COOH in $POCl_3$. Many solutions which, according to molecular weight determinations, are undissociated, conduct well. Thus $AgNO_3$ has a normal molecular weight in pyridine and benzonitrile, yet it conducts fairly well. According to Dutoit and Friderich, CdI_2, LiCl, NaI, $HgCl_2$ and NH_4CNS have normal molecular weights in acetone, and yet these solutions are conductors. Walden has found that KI, NaI, RbI, NH_4I and KCNS conduct well in liquid SO_2, and yet have abnormally large molecular weights in this solvent. Franklin and Kraus have found that while NH_4NO_3, $NaNO_3$ and KI dissolved in liquid ammonia are excellent conductors, the boiling points of the solutions are not nearly so high as they ought to be according to the ionisation theory. Nicolo Castoro found by means of the freezing-point method that $AgNO_3$, $CdCl_2$, $HgCl_2$ and $ZnCl_2$ have normal molecular weights in urethane; yet the author has found that the first three of these solutions are conductors. Recently, Innes found the molecular weights of succinic, salicylic and tartaric acids to be normal in pyridine according to the boiling-point method; preliminary tests by the author have shown that all three of these solutions are fairly good conductors.

In the case of non-aqueous solutions the various methods of observing ionisation do not always give the same indication with increasing dilution; it is sometimes in one direction and sometimes in the other. Occasionally simple substances in solution show abnormally low molecular weights, and yet are non-conductors. The author has found this to be so in the case of solutions of diphenylamine in methyl cyanide.

The abnormal behaviour, according to the theory, of non-aqueous solutions led the author to investigate aqueous solutions somewhat further.

Experimental Part.—The investigation consisted of four parts:—(1) Determination of boiling points of aqueous solutions of typical, common, chemical compounds from low to very high concentrations, to see how the molecular weight changes with the concentration. (2) Measurement of the conductivity of these solutions at or near their boiling points. These two parts of the work were carried out by Mr. A. A. Koch. (3) Measurement

[1] Abstract of a paper by Mr. Louis Kahlenberg in the *Journal of Physical Chemistry* (vol. v. pp. 339–392, June, 1901).

of conductivity at 0°. These determinations were made by Mr. R. D. Hall. (4) Cryoscopic determination of the molecular weights. The results of (1) and (2), and also of (3) and (4), were comparable, being under similar conditions.

The conductivity determinations were made by means of the usual Kohlrausch method with a telephone. The measurements at 0° were made in baths of melting ice. Those near the boiling point were not carried out at the boiling point, but at 95°, as small gas bubbles were apt to form at the electrodes at 100°. The freezing-point determinations were made with a regular Beckmann's apparatus of large size, about 40 grammes of water being used in each case. The solutions were cooled only from two to three tenths of a degree below their freezing points, and the crystallisation was inaugurated by means of a point of ice. The boiling-point determinations were made with a Beckmann's apparatus of about double the ordinary size, and thermometers graduated to 0°·01. It was at first thought best to surround the thermometer with a platinum cylinder in the boiling tube, as recommended by Jones, but fluctuations in the boiling point were found to result, apparently due to the solution within the cylinder being more concentrated than that without.

The water used was distilled in a block-tin condenser and had its conductivity reduced to 2×10^{-6} by drawing air through it free from carbon dioxide. In the results given, the conductivity of the water at the proper temperature has been deducted. Water of crystallisation was determined and allowed for in making up solutions, these being based on the amount of anhydrous salt present.

Conductivity measurements at 0° and at 95° are given for NaCl, KCl, KBr, KI, $MgCl_2$, $BaCl_2$, $HgCl_2$, $KClO_3$, KNO_3, $AgNO_3$, $MgSO_4$, $ZnSO_4$, $MnSO_4$, $CdSO_4$, $NiSO_4$, $CoSO_4$, $FeSO_4$ and $CuSO_4$. The volume in litres containing a gramme equivalent was varied from ¼ to 8192 in the case of the determinations at 0°, and from ½ to 2048 in the case of those at 95°. The results show an increase of the equivalent conductivity with dilution and the same trend in the curves at the two temperatures, but they are not parallel. For example, the curve between equivalent conductivity and the cube root of the volume is nearly a straight line for $MgSO_4$ at 95°, but much more curved at 0°. Curves of salts belonging to any one group all have the same trend.

The freezing-point determinations include NaCl, $MgSO_4$, $ZnSO_4$, $MnSO_4$, $CdSO_4$, $NiSO_4$, $CoSO_4$, $FeSO_4$ and $CuSO_4$. The results are summarised below :—

Sodium Chloride.—For about 0·2 normal solution the molecular weight was found to be 32·6, equivalent to 79·4 per cent. ionisation; for an approximately normal solution (the strongest used) the molecular weight was 31·7, equivalent to 84 per cent. ionisation. According to the conductivity tests the ionisation is about 79 per cent. for a 0·2 normal solution and 70 per cent. for the normal solution. The results are, therefore, about the same by both methods for the dilute solution, but whereas the ionisation increases rapidly with dilution according to the conductivity, it remains constant or diminishes according to the cryoscopic method. This result is confirmed by the work of C. Dieterici and of R. W. Wood.

Magnesium Sulphate.—The limits were about 0·1 and 1·5 normal. The degree of ionisation for the first was 40 per cent. and for the second only 5 per cent. According to the conductivity measurements the ionisation should be 44 and 22 per cent. respectively, showing an increasing discrepancy with concentration.

Zinc Sulphate shows no ionisation in a normal solution, yet the conductivity is nearly the same as that of $MgSO_4$, and indicates 24 per cent. ionisation. The molecular weight in the strong solutions was above the normal.

Manganous Sulphate shows at first an increase of molecular weight with concentration and then a decrease. The same is true of $ZnSO_4$ and $CdSO_4$, and to a slight extent of $NiSO_4$, $CoSO_4$ and $CuSO_4$. According to the conductivity of these solutions, the ionisation increases constantly with the dilution, but according to the cryoscopic measurements there is first a decrease and then an increase with increasing concentration. An approximately N/4 solution of $MnSO_4$ gave a molecular weight of 125·2, or 21 per cent. ionisation, the conductivity method giving 35 per cent. In a solution giving a molecular weight of 146·5 the ionisation is 3 per cent., whereas conductivity indicates 20 per cent.

Cadmium Sulphate, though a good conductor, shows no ionisation except in the most dilute solution (3·071 gm. $CdSO_4$ in 100 gm. of water), which gave 12 per cent. ionisation, the conductivity indicating 30 per cent.

Nickel Sulphate appears to be un-ionised when the strength is 10 per cent., but the conductivity shows 22 per cent. ionisation. In the most dilute solution the two methods gave about the same result.

Cobalt Sulphate.—The freezing point shows no ionisation when the solution is 5 per cent. or stronger, whereas the conductivity indicates 26 per cent. when the observed molecular weight is 155·2. In the most dilute solution the molecular weight was 131·8, corresponding to 18 per cent. ionisation, the conductivity indicating 34 per cent.

Ferrous Sulphate also is un-ionised in 6 per cent. solutions or above, according to cryoscopic determinations, yet the conductivity indicates 24 per cent. ionisation when the observed molecular weight is 154·8 (*i.e.* above the normal), and ionisation should be absent. The most dilute solution showed a molecular weight of 135·8, or 12 per cent. ionisation, the conductivity indicating 30 per cent.

Copper Sulphate is like the last two salts. When the observed molecular weight is 163·9, corresponding to no ionisation, the conductivity indicates about 22 per cent. In the most dilute solutions tested the molecular weight corresponds to 38 per cent. ionisation and the conductivity to 32 per cent.

The results obtained with copper sulphate are as follows, similar results for the other salts being given in the original paper :—

Copper Sulphate (*$CuSO_4$*). *Molecular Weight*, 159·7.

Amount of $CuSO_4$ in 100 gm. water.	Lowering of freezing point.	Molecular Weight.
1·835	0·300	115·6
3·312	0·405	154·6
6·443	0·743	163·9
9·242	0·996	175·4
14·210	1·569	171·2

The agreement, therefore, of the methods, viz. conductivity and freezing points, is poor, even in the dilute solutions. Arrhenius originally gave figures from cryoscopic measurements indicating no ionisation for $MgSO_4$, $FeSO_4$, $CuSO_4$, $ZnSO_4$, $CdSO_4$ and CdI_2, whereas ionisation was indicated by conductivity. He sought to explain this, in the case of the sulphates, by polymerisation of the un-ionised molecules, basing this assumption on the fact that Hittorf found the migration numbers of $MgSO_4$ and $ZnSO_4$ to show a considerable variation with concentration. This was also true of CdI_2, for which Hittorf consequently assumed double molecules, and applied the same explanation to other salts of the magnesia series. This at first seems to justify the position taken up by Arrhenius. However, the latter has not applied the explanation to all salts of the magnesia series, but has assumed polymerisation simply for those salts that did not behave according to his theory. $MgCl_2$ is a case in point. Similarly, Hittorf found the migration numbers of $CaCl_2$, $BaCl_2$, $Ca(NO_3)_2$ and $Ba(NO_3)_2$ strongly dependent on concentration, but Arrhenius did not assume polymerisation, for these salts agree better with his theory. To assume polymerisation in the case of $MgCl_2$, $CaCl_2$ and $BaCl_2$ would render it difficult to explain the results of Jones and Chambers, who found a minimum for the molecular lowering between 0·1 and 0·2 normal, and that the lowering in concentrated solutions was as great as, or greater than, that corresponding to complete ionisation. These authors attempt to explain this by assuming that the salts form hydrates. Thus another theory is brought in to account for abnormally low freezing points, to explain which the ionisation theory was itself originally introduced. Results of a similar kind have been observed by C. Dieterici.

The boiling-point determinations given by the author refer to NaCl, KCl, KBr, KI, $MgCl_2$, $BaCl_2$, $HgCl_2$, $KClO_3$, KNO_3, $AgNO_3$, $MgSO_4$, $ZnSO_4$, $MnSO_4$, $CdSO_4$, $NiSO_4$, $CoSO_4$, $FeSO_4$ and $CuSO_4$.

In the case of NaCl, KCl, KBr and KI the molecular weights continually diminish with increase of concentration, finally becoming less than half the theoretical values, whereas the molecular conductivity increases regularly with the dilution.

The molecular weight of $MgCl_2$ and of $BaCl_2$ decreases with increasing concentration until it becomes less than one-third the theoretical value, but the conductivity in both cases increases with the dilution.

$HgCl_2$ shows no ionisation by the boiling-point method. The molecular weight increases with concentration. It might be assumed that polymerisation takes place and, further, that some of the molecules which are not yet polymerised are ionised and thus account for the conductivity, which, though low, increases with the dilution.

In the case of $KClO_3$, KNO_3 and $AgNO_3$ the molecular weight increases with concentration, and there is good agreement with the conductivity measurements. Thus $AgNO_3$ in the most dilute solution tested appeared to be ionised to the extent of 65 per cent., while the conductivity method showed 67 per cent. For a normal solution the boiling-point method indicated 54 per cent. and the conductivity 52 per cent. The agreement is closer at the boiling point than at the freezing point.

In the case of $MgSO_4$ the molecular weight begins, in the dilute solution (2·733 gm. in 100 gm. of water), with a value above the theoretical, indicating no ionisation; then it increases with the concentration, and finally decreases after passing through a maximum, the values in the concentrated solutions becoming less than the theoretical. But there is no irregularity in the conductivity values. What has been said of $MgSO_4$ applies also to $ZnSO_4$, $NiSO_4$ and $CuSO_4$. The same general behaviour is also exhibited by $MnSO_4$, $CdSO_4$, $CoSO_4$ and $FeSO_4$, except that the molecular weights of these salts, while first increasing and then decreasing with increase of concentration, always remain above the theoretical values. The molecular weight of the sulphates is less by the freezing-point results than by the boiling-point method. So that if it be assumed that the molecules are polymerised, this polymerisation is greater at the higher temperature.

A series of boiling-point determinations was made on a solution of cane sugar, as an example of a non-electrolyte. It was found that the molecular weight diminished appreciably as the concentration increased, becoming less than the normal (212 in a solution of 289·4 gm. in 100 gm. of water, as compared with the normal 342). But, as is well known, the solution does not conduct. A test with Fehling's solution showed that no invert sugar had been formed by the boiling. Solutions of H_3BO_3, on the other hand, show practically constant molecular weight with varying concentration.

Discussion of Results.—From the above results it appears that there are solutions which are excellent conductors and which, nevertheless, show a normal molecular weight of the solute. While in some cases the molecular weight increases with the concentration, thus agreeing qualitatively at least with the ionisation theory, in other cases the molecular weight decreases with increase of concentration, finally becoming less than what it ought to be even for complete ionisation. In other cases the molecular weight at first increases with concentration and then diminishes. But the conductivity of these solutions continually increases with dilution. There are cases, however, in which the conductivity at first increases with the dilution and then decreases, *e.g.* aqueous solutions of the alkaline hydroxides.

It follows, therefore, that there is no such connection between freezing points and boiling points of solutions on the one hand and their conductivity on the other as is claimed by the ionisation theory. Often there is not even a qualitative agreement. Want of agreement is to be found in the original table of Arrhenius, but this was ascribed to experimental errors.

Various properties of electrolytes have been explained by the ionisation theory. Thus the various additive properties of salt solutions are presented as supporting the theory. But the theory cannot be based on additive properties of this kind, for such are known to exist in the case of true chemical compounds, where, since there are no solutions under consideration and since there is no electric conductivity observable, the possibility of ionisation is out of the question. In the realm of physiology, also, the theory cannot cope with the facts.

The heats of neutralisation of acids and bases have been used as an argument in favour of ionisation; Crompton, however, has shown that the theory is not only unnecessary, but that it is inadequate. Again, the theory cannot be brought into harmony with the law of mass action, which is one of the strongest arguments against it.

The chemical reactiveness of electrolytes has been explained by attempting to ascribe to the ions a peculiarly strong chemical activity on account of the electrical charges that are supposed to reside upon them. In this connection attention is drawn to the action of water in frequently facilitating chemical action. While this fact may be in agreement with the ionisation theory, it cannot be used to support it; for there are many pure substances and mixtures that are very active, although there is no ground for assuming the presence of ions; *e.g.* many explosives. It is well recognised that many bodies unite with the solvent, and interaction then takes place between the new products, reactions taking place which might easily not occur between the original anhydrous bodies.

It has been supposed by Nernst and by J. J. Thomson that the higher the dielectric constant of a solvent the greater its ionising power. But many exceptions are now known, *e.g.* liquid NH_3, butyronitrile and pyridine (H. Schlundt), liquid SO_2 (Walden), liquid HCN, and amylamine.

That the ionising power of solvents is dependent upon the polymerisation of their molecules, as claimed by Dutoit and Aston, has been shown to be incorrect in many cases by Kahlenberg and Lincoln.

The ionisation theory is at its best in explaining electrolysis, but there are many phenomena which the theory does not explain. For example, why are the deposits of silver from some solutions poorly adherent and from others dense and well adhering, the potential difference and current density being the same?

As to the ionisation theory being required by thermodynamics, Clausius, who showed the discrepancy in the Grotthus theory, did not find it necessary to put forth such a radical hypothesis as that of Arrhenius. Nor did Hittorf find it necessary to frame such a theory. Finally, no marked improvements or discoveries in electrolysis are due to the theory. It has led to Nernst's theory of the E.M.F. of galvanic cells and a formula which really involves the assumption that the law of mass action is applicable to electrolytes in the sense required by the ionisation theory. That this law does not hold has already been mentioned. By maintaining the correctness of this formula and thus assuming that the law of mass action holds for electrolytes, Jahn has arrived at the conclusion (as clearly he must) that the ratio of the equivalent conductivity at a given concentration to that at infinite dilution does not correctly represent the degree of ionisation, and that the ionic velocities vary in dilute solutions. This has given rise to a discussion in the *Zeits. Phys. Chem.*

If the ionisation theory is not true, then the original difficulty with the van 't Hoff theory of solutions recurs, viz. the theoretical interpretation of the factor i in the gas equation. Of course this equation is supposed to hold strictly only for ideal gases. A normal solution, however, is rather dilute for many of the practical purposes of life. Not that one expects the gas equation to hold strictly for a normal solution, but what one has a right to expect from the modern theory of solutions is that, with increasing concentration, a solution should behave at least qualitatively as a gas does with increase of pressure. The ionisation theory does not satisfactorily explain the significance of the factor i. In any case this factor should never be placed equal to unity without experimental evidence, whether in connection with electrolytes or non-electrolytes.

Substances of similar chemical composition, when dissolved in the same solvents, behave similarly so far as boiling points or freezing points are concerned; this shows that the influence of the chemical nature of the solute affects these variations.

The analogy between gases and solutions has been pressed too far, so that it has been forgotten that we are dealing only with an analogy. The solution of a substance and the expansion of a gas are really very different. A gas will expand in vacuo or mix with any other gas, but a substance will not dissolve in every liquid. And here lies the difficulty of the theory. It neglects the all-important *rôle* of the solvent. It fails to emphasise the fact that the process of solution takes place because of a mutual attraction between solute and solvent, and this attraction is the essence of the so-called osmotic pressure, which is closely related to, if not essentially identical with, chemical affinity. The attraction between solvent and solute should be recognised. Each solution should be examined separately, beginning with the most concentrated, the behaviour of the most dilute solutions appearing as a limiting case; then we shall see the present theory of solutions in its true relation to the facts.

W. R. C.

AN ITALIAN ELECTRIC RAILWAY.

THE motive power on our great railways forms such an important question that any enterprise made with a new motive power, electricity or otherwise, adapted so as to utilise the existing rolling-stock, not only may at some future time greatly accelerate the present speed, but also introduce great economies, especially if the new power can be derived from a natural source. In Italy the railway authorities have been thoroughly alive to this fact; a portion of the railway of northern Italy has been electrically equipped for running by means of electric motors, as a pioneer installation, and if successful the remainder will be similarly equipped. The Valtellina electric railway (says *Feilden's Magazine* for January), which is sixty-two miles long, runs from Lecco along the shores of Lake Como to Colico, where it divides, one branch going to Sondrio and the other to Chiavenna. The power of the line is furnished by falling water from the river Edda, which operates four turbines (2000 h.p. each) and which, coupled direct with four Schubert three-phase generators, give a current at 20,000 volts and 15 cycles. This current is led to ten substations (placed about six miles apart) along the route, where it is transformed to 3000 volts, at which voltage the various sections of the line are fed. The two overhead trolley wires which supply the motors (the railway track forming the third) are hung from steel wires supported on each side by posts spread with crossbeams; these also carry the main supply wires (20,000 volts). The traffic of the line comprises both goods and passenger, and it is worthy of note that for the former electric locomotives are used for the haulage of the wagons (which are of the standard Italian type), and for the passenger traffic bogie motor-cars act in place of locomotives and pull four coaches as trailers (these latter also of the ordinary Italian type). A train of this description is run at thirty-nine miles per hour on all gradients less than 10 per cent.; for anything steeper than this "the Cascade" arrangement of motors is used, then the speed is halved. The speed of the goods traffic is twenty miles per hour with a load of 250 tons. The line is equipped with every facility for safe working, everything being made as automatic as possible. For instance, "when a train receives a block signal it also has its current cut off so that it cannot proceed." Again, "where a train is coming up at full speed, and it is necessary to order it to stop owing to sudden occurrence of something in front, the signalman not only makes the signal to stop, but he also cuts off the current and applies the full brake power available to the advancing train." Lightning has been fully guarded against. The power house is supplied with a group of conductors of the "Horn" type outside the building, and lightning arresters of a similar type are fitted in the substations, and, lastly, the electric locomotives and motor-cars have also similar apparatus fitted. The working of the line will not only be watched with interest, but also forms an important example of electric traction on account of its newness in design (especially in detail), and the thorough way in which the system is made automatic and interlocking and also safely guarded against accidents.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. W. E. Johnson, of King's College, has been appointed the first Sidgwick lecturer in moral science.

The Balfour studentship in animal morphology will be vacant at Lady Day next. Applicants are requested to send their names, with such information as to their qualifications and proposed researches as they may think desirable, to Mr. J. W. Clark, Scroope House, Cambridge, by February 28.

The complete degree of M.A. *honoris causa* is to be conferred on Dr. W. E. Dixon, London, assistant to the Downing professor of medicine.

THE proposal to establish a University of Liverpool was warmly supported at a meeting held at the Liverpool Town Hall on Monday, the Lord Mayor of the city being in the chair. At the close of the meeting it was announced that the sum of 80,000*l.* has been promised in support of the scheme.

THE Lord Lieutenant of Berks (Mr. J. Herbert Benyon) has been elected president of Reading College, in succession to the late Lord Wantage. A fund of 1000*l.* a year for five years has been raised to augment the existing income. Lady Wantage, Mr. Benyon and Mr. Alfred Palmer have each contributed 250*l.* a year to this fund.

IT is proposed to erect a bronze tablet in the museum at Marischal College, Aberdeen University, in honour of the late Prof. H. Alleyne Nicholson. Prof. J. Arthur Thomson and Mr. J. E. Marr, F.R.S., have undertaken the preliminary steps and are prepared to receive subscriptions from "those who were friends, colleagues, collaborateurs or old students" of Prof. Nicholson.

MR. T. J. I'A BROMWICH, Fellow of St. John's College, Cambridge, has just been appointed professor of mathematics in Queen's College, Galway, in succession to Prof. A. C. Dixon, lately appointed professor of mathematics in Queen's College, Belfast. Mr. Bromwich graduated as senior wrangler in 1895, and subsequently obtained a first class (first division) in the second part of the mathematical tripos. Since taking his degree he has made a number of original contributions to various branches of mathematics.

ANNOUNCEMENT is made in the *Times* that Lord Curzon, the Viceroy of India, has appointed a commission to visit the University centres and colleges of India to inquire into their prospects, report on their working, and recommend measures for the improvement of the teaching and the standard of learning. The commission is composed as follows:—Mr. T. Raleigh, president; Syad Hossain Bilgrami Nawab; Mr. J. P. Hewett, Secretary to the Home Department; Mr. A. Pedler, Director of Public Instruction in Bengal; Prof. A. Bourne, Principal of Madras College; and the Rev. Mr. Mackichan, Principal of Wilson College, Bombay. Mr. R. Nathan will act as secretary.

PROTESTS are being made against the dissolution of Victoria University. It is suggested that there might be one great University for the north and not several connected with single cities. At a meeting of graduates of Victoria University held at Leeds on January 24, a resolution was unanimously adopted expressing the conviction that to abolish the Victoria University would be detrimental to the interests of higher education in the north of England. A committee was appointed to attend an approaching meeting at Manchester in connection with the Victoria University and protest against its disruption. The board of governors of the Yorkshire College, Leeds, has adopted a resolution expressing the view that though the dissolution of the Victoria University in favour of separate universities would be detrimental to the interests of education in the north of England, still, having regard to the resolutions passed by Owens College, Manchester, and University College, Liverpool, preparations should be made for the establishment of a University for Yorkshire based upon the existing Yorkshire College, with provision for the admission of other constituent colleges and for the affiliation of other suitable institutions.

THE annual meeting of the Association of Directors and Organising Secretaries for Technical Education was held on Friday last. Mr. A. Keen, the president, delivered an address dealing with the question of rural education. He urged that what are wanted are:—(1) A system of suitable elementary instruction which should include practical work in every standard; (2) a good supply of secondary schools at low fees of the rural grammar school or modern school type, taking, say, the Rural School of Science course in the Government Directory, and such other studies as the circumstances of different districts might direct; (3) a more limited supply of higher secondary schools of the high-grade grammar school type for boys and girls who were intended to continue their education beyond the usual age, and probably go to a university or some other place of advanced education; and (4) for the benefit of boys intended to be farm bailiffs, agents, stewards, farmers, or market gardeners, and especially those who had no suitable means of acquiring at home an intimate knowledge of farm and garden work and general practical experience, there should be in every large county, and in every group of smaller ones, a farm school, or an agricultural school or college, for boys of fifteen to sixteen years of age and upwards, providing a course of instruction for two or three years of a thoroughly practical character.

AN interesting introductory address delivered by Prof. Wilson, professor in anatomy at Sydney University, has been sent to us. The address is entitled "Ideals in Medical Education"; it is

well worthy of careful perusal, and in a short paragraph only the very salient points can be touched upon. The author begins with a plea for centralisation and a note of warning against the multiplication of universities, when ample means are not to hand for their equipment. Local convenience is undoubtedly an important consideration, as is also emulation between districts for the possession of intellectual centres, but both of these should be subordinate to the true interests of education. The equipment of the modern university is necessarily a very costly matter. The next point we can consider is the length of the medical curriculum. Prof. Wilson directs attention to the value of general education to the medical student, and views with regret the abolition by many universities of the obligatory preliminary degree in "Arts." In this connection he refers to the new regulations at Harvard, in which it has been enacted that the medical student shall undergo a preliminary four years' course in arts before entering upon his four years' medical curriculum. In view of the present controversy concerning elementary medical education, it is of interest to note that the author appears to accept the general educational value of special medical studies, but is apparently not in favour of the relegation of physics, chemistry and biology to the schools. The chief reason against this is the assumption that it would still add another year to the curriculum, and "this might be as well done frankly under university guidance." It may be objected, however, that the boy could perfectly well begin these studies at sixteen, and it is certainly a very open question whether at such an age he is better at the school or university. With regard to pharmacology, Prof. Wilson would relegate the experimental part entirely to the physiologist and the therapeutical part entirely to the physician. He apparently does not see in pharmacology as at present taught what he describes so accurately in the case of general pathology, namely, a "bridge-like" position in the medical curriculum, fitting the student, when essentially pursuing the intermediary subjects, for the problems awaiting him in the wards, and enabling him to utilise to the full the relatively small clinical experience which he will obtain. In conclusion, Prof. Wilson admits that the medical curriculum is at present full to overflowing, and recommends a somewhat novel plan to relieve it. He suggests, and instances certain American universities as precedents, a more universal use of the honours system. He would establish a system of "elective studies," would allow the student to specialise earlier in his career, and while demanding certain evidence of all-round knowledge, would very considerably reduce the standard in it, according to the depth and thoroughness of the work done by the student in certain directions. It must be admitted, however, that the magnitude of the irreducible minimum would be difficult to decide, as would also the thoroughness of "work done by the student in certain directions."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, May 23, 1901.—"On the Intimate Structure of Crystals. Part v.—Cubic Crystals with Octahedral Cleavage." By Prof. W. J. Sollas, F.R.S.

November 21, 1901.—"On Skin Currents, Part ii. Observations on Cats." By Augustus D. Waller, M.D., F.R.S.

In part i. it was stated that the normal electrical response of frog's skin to excitation is outgoing, from internal to external surface. In the skin of the pad of the cat's foot the electrical effect of excitation of the sciatic nerve proved to be ingoing, as stated by Luchsinger and Hermann. Dr. Waller determined this fact by decapitating cats and immediately testing the effect of excitation of the sciatic nerve on the pad of the foot; the effect gradually declines and disappears an hour after decapitation. It is pointed out that this experiment on a freshly killed animal is a convenient class demonstration of a fundamental fact which it has hitherto been thought necessary to demonstrate on living animals. The effect is elicited after the sciatic has ceased to provoke muscular contraction; the largest response observed and photographed was ·0100 volt, the lost time was three seconds.

In order to observe the response to direct excitation, the pad of a cat's foot was cut off and set up between unpolarisable electrodes; during the first forty-eight hours there is a normal ingoing current of ·0100 volt. If after exact compensation of this current a single induction current is sent in in either direction, the after-effect is nearly always outgoing, as in frog's skin; an ingoing effect is observed with a fresh skin and weak excitation.

Dr. Waller thinks it probable that both ingoing and outgoing forces may co-exist in the excited skin, the galvanometer expressing the resultant. In order to investigate the causes of the variability of the direction of response, the A B C method is devised:—Three electrodes are applied to the external surface of the skin, the third electrode C being used to examine separately the effects at A and B. By means of an especially designed switch called the M-shaped switch, an excitation can be applied at A and B, and the response led off through C and A, or C and B. The response is found to be always an outgoing current at A or B for both directions of excitation.

Physical Society, January 24.—Prof. S. P. Thompson, president, in the chair.—A paper on the factors of heat was read by Mr. James Swinburne. In all branches of physics, except heat, energy is divided into pairs of factors. Heat is generally thought of as a sort of indivisible energy and is not split into factors, but is treated as a whole, so that we have conductivity for heat, capacity for heat, specific heat, &c. Capacity for heat and specific heat are also taken when they include external work, at constant pressure for instance; so that the capacity is reckoned as capacity for energy which is only partly in the body or substance. So little is heat realised as energy that it has its own unit, so that equations involving other forms of energy with it need to be complicated with a coefficient. Temperature might be a factor of heat, but there is no corresponding quantity factor. There is no unit of temperature, it is measured in degrees which have no proper connection with anything. Temperature is sometimes treated as a tension factor with heat as the quantity factor, as when heat is said to run down temperature. Heat is thus regarded as its own quantity factor. Entropy is sometimes incorrectly used as the quantity factor corresponding to temperature. Entropy is at present indispensable as a function involving information as to whether heat has been or might have been converted into work. The author discusses "chy" as a possible factor for use with absolute temperature where "chy" is a quantity factor such that when multiplied by the temperature at which it is added or withdrawn gives the energy added or withdrawn. In the θ, χ system capacity, specific capacity and conductivity vary inversely as the temperature. These factors are not analogous with the factors of other forms of energy and are not convenient. The energy of heat is therefore split into $\tau\,\pi$, where τ is proportional to the square root of the temperature and is called by the author "tasis." The other factor, π, is called "posot." In any gas, tasis is proportional to the effective velocity and posot to the momentum. Tasis and posot are analogous to the tension and quantity factors already in successful use and indispensable in the treatment of other forms of energy. Conductivity of posot follows Ohm's law and the capacity of a body for posot is constant.

Chemical Society, January 16.—Prof. J. Emerson Reynolds, V.P.R.S., president, in the chair.—An investigation of the radio-active emanation produced by thorium compounds, by Prof. Rutherford and Mr. Soddy. The authors have previously shown that whilst thoria gives rise to a Becquerel radiation, it also communicates to gases passed over it a radio-active substance referred to subsequently as the emanation. They find that the emanating power of the oxide is destroyed by heating and can be restored by reprecipitation, and, further, that probably the emanating power is not a specific property of thoria, but is due to the presence of some foreign substance. As regards the nature of the emanation itself, it appears to be a gas of the argon type, since it is not destroyed by such powerful agents as red-hot lead chromate, white-hot platinum black, red-hot magnesium, &c.—The constitution of hydrocyanic, cyanic and cyanuric acids, by Dr. F. D. Chattaway and Mr. Wadmore. It is generally assumed by chemists at the present time that in these substances the hydrogen is joined to carbon and that they must be represented by such formulæ as H.C⋮N, HO.C⋮N, &c. The view that they are really the *iso*-compounds of the formulæ C:N.H, O:C:N.H, &c., is again brought forward by the authors, and the evidence afforded by the behaviour of the haloid cyanogen compounds—which is that of substances containing the haloid joined to nitrogen—is shown to necessitate their representation by such *imino*-formulæ.—A modification of Zeisel's method for the estimation of methoxyl groups, by Dr. J. T. Hewitt and Mr. T. S. Moore. The

complicated apparatus designed by Zeisel is greatly simplified by the substitution of a fractionating column consisting of nine aludels, alternately closed and open, arranged in series in a glass tube, for the sloping condenser with water at 40° C. and the washing bulbs containing amorphoric phosphorus. Results obtained with codeine and quinine proved that this rearrangement is effective in retaining iodine and hydriodic acid.—A new colour reaction of hydroxylamine, by Mr. W. C. Ball. When a solution of hydroxylamine or its salts is boiled with a solution of ammonium-sulphite until sulphur begins to form and to the liquid a strong solution of ammonia is added, together with a few c.c. of alcohol, a fine purple colour is produced which is visible when only one part of hydroxylamine in 500,000 of water is used.—On the sensitiveness of a thermoregulator, by Mr. A. W. C. Menzies. A description of an apparatus whereby a definite temperature may be maintained over considerable periods with a maximum variation of ·0025 of a degree.—Myricetin, Part ii., by Mr. A. G. Perkin. An account is given of the methyl and ethyl ethers of this colouring matter, extracted from the bark of the Indian tree *Myrica nagi*, and which has already been shown by the author to be a hydroxyquercetin. Myricetin appears not to occur free in the plant, but in the form of a rhamnose ether (glucoside), which has been named *myricetrin* ($C_{21}H_{22}O_{13}$).—The colouring matters of green ebony, by Messrs. A. G. Perkin and S. H. C. Briggs. This dyewood contains (*a*) *excoecarin*, $C_{13}H_{12}O_5$, easily oxidised by bromine to *excoecarone*, $C_{13}H_{10}O_5$, and hydrolysed by potash fusion to hydroquinone carboxylic acid. (*b*) Jacarandin, $C_{14}H_{10}O_3(OH)_2$, which appears from its reactions to belong to the quercetin series of dyes.—The action of methylene iodide on aryl- and naphthylamines; diaryl methylene diamines, acridines and naphthacridines, by Dr. Senier and Mr. Goodwin. With anilines, toluidines and xylidines, diamines are formed, but with amine of condensed substances such as naphthalene, bodies of the acridine type are produced.—The polymerisation of cyanic acid, by Dr. Senier and Mr. T. Walsh. In this reaction cyamelide is not, as is generally supposed, the only product, a quantity of cyanuric acid being also formed.

Mathematical Society, January 9.—Dr. Hobson, F.R.S., president, in the chair.—The president (Major MacMahon, F.R.S., vice-president, in the chair, *pro tem.*) communicated a paper on non-uniform convergence and the integration of series. Messrs. Larmor, Love, Whittaker and the chairman spoke on the subject of the paper, which followed out the work of Prof. Osgood.—Mr. S. Roberts, F.R.S., read a paper on networks. This paper treats of certain networks (1) with triangular meshes, (2) with polygonal meshes. They are intimately connected with the problem of colouring maps with four colours only. The doubts and difficulties which have arisen with regard to the demonstration of the general theorems involving the solution of the problem in question show the expediency of discussing limited and defined cases and passing to more general results step by step. The subject, the author says, is, in fact, larger and more intricate than the simplicity of the empirical solution would lead one to expect. The late Prof. Tait's theorem is animadverted upon and is considered to have been enunciated in too general a form. In connection herewith reference is made to Prof. Petersen's communication (*cf.* "L'Intermédiaire des Mathématiciens," vol. v., p. 226). But it is not certain that Prof. Tait was responsible for the unguarded statement (*cf. Phil. Mag.*, vol. xvii. pp. 30, &c.). In any case Prof. Petersen's example shows that the theorem is not absolutely general.—The president communicated a paper by Mr. W. H. Young, on the fundamental theorem of differential equations. The fundamental theorem of the modern theory is Cauchy's existence theorem, dealing with the existence and uniqueness of a set of integrals satisfying given initial conditions and the holomorphic character of the solution. Some doubt has been expressed as to whether the proofs furnished by Picard and Painlevé are rigorous. It has been suggested that it has not been conclusively demonstrated that the holomorphic solution is unique even in the simplest case which can arise. The paper gives a brief account of the theorem in question, and examines an example which has been put forward as typical of a large class of cases where the theorem fails.—A paper by Prof. W. Snow Burnside, on the integrals of the differential equation

$$\frac{du}{\sqrt{f(u)}}+\frac{dv}{\sqrt{f(v)}}=0, \text{ where } f(x)\equiv aax^4+4bx^3+6cx^2+4dx+e,$$

considered geometrically, was communicated by title.

Geological Society, January 8.—Mr. J. J. H. Teall, V.P.R.S., president, in the chair.—A system of glacier-lakes in the Cleveland Hills, by Mr. P. F. Kendall. After referring to existing "extra-morainic" lakes, such as the Märjelen See and those of the Chaix Hills, the author proceeds to deal with the criteria for the recognition of such lakes. These include beaches, deltas, floor-deposits and overflow-channels. Shore-scarps are common in Cleveland, but beaches are rare or absent, the reason being in part that stability was rarely secured owing to the overflows being over soft Jurassic strata. Deltas also are not common. The floor-deposit of lakes may be distinguished from river-alluvia by the fact that the lamination is close and regular, but, being parallel to the subjacent surface, it may be highly inclined. On the other hand, alluvia are laid down on horizontal surfaces, but rarely show good lamination. Evidence from borings and drift-filled channels is given to show that during or before the Glacial period the land was considerably above its present level. The Glacial deposits are described in detail from sections and borings, some of them carried out by the author, and the assemblages of boulders are identified and classified into three chief groups—a western group, from the Solway, Vale of Eden, Stainmoor Pass and the Tees; a northern group, from the Tweed and Cheviots and from eastern Durham; and an eastern group, from the Christiania region, the Gulf of Bothnia and Denmark or the North Sea. The author has been unable to detect any signs of the presence of the sea in this area at any time during the Glacial period. Three main ice-masses appear to have been concerned in producing the deposits—one from the southern Uplands and the Solway, joined by the local ice of the Tees; a second originating in the Tweed Valley, and driven southward round the Chevoits by the pressure of the third, or Scandinavian, ice-mass. The general order of events is supposed to have been: (1) the unobstructed passage of the Teesdale glacier to the coast, (2) the arrival of the Scandinavian ice, and (3) the invasion of the Scottish ice. The first of the extra-morainic lakes described is that of the Vale of Pickering, the lowest of the sequence, which for a long period received all the drainage of the district except that of the western margin, and the outflow from which into Lake Humber was that now occupied by the River Derwent. Newton Dale was the outflow of the lake-series of the Eskdale country. The Eskdale system comprises a series of lakes connected by an "aligned sequence" of overflows; and here it is possible to trace the consequences of the shrinkage of the ice-masses and to follow out the low-level phases of the lake. The ice pressing upon the northern face of the Cleveland Hills gave rise to a series of lakelets, connected with which are the following set of overflows:—Scugdale and Scarth Nick, Bilsdale, Kildale, Ewe Crag Beck, Tranmire, and Egton Moor. Iburndale contained a lakelet overflowing eastward. Behind a narrow coast-strip of country, extending from Robin Hood's Bay to Hunmanby, there runs a gorge which receives all the drainage of the "hinterland" and carries it into the Vale of Pickering. In the production of this arrangement the effects of an ice-sheet shutting the seaward ends of the valleys are traceable; the position of the main overflows was stable, and the drainage was permanently deflected.—The glaciation of Teesdale, Weardale and the Tyne Valley, and their tributary valleys, by A. R. Dwerryhouse. After an account of the topographical solid geology of Teesdale, the author describes four distinct types of drift in the area. A detailed description of the Glacial deposits, boulders and striæ is given, and from this the following conclusions are deduced:—Upper Teesdale was heavily glaciated by local ice from the eastern slope of the Cross Fell Range; this part of the Dale was not invaded by any other ice, and the higher peaks stood out as nunataks. At the period of maximum glaciation a number of lakes were formed, owing to the obstruction of the drainage of lateral tributary-valleys by the ice of the main glaciers. Lunedale was occupied by ice (the Stainmoor glacier) which came from the drainage-basin of the Irish Sea, joined the Teesdale glacier about Middleton-in-Teesdale, and by its thrust deflected the Teesdale ice into the valley of the Wear. During the retreat of the ice there was a lengthened period of "constant level," when well-marked drainage-channels were formed, and after this the ice was removed with great rapidity. A tongue of ice flowed from Upper Teesdale by Yad Moss to the Valley of the South Tyne.

Zoological Society, January 14.—Prof. G. B. Howes, F.R.S., vice-president, in the chair.—Dr. A. S. Woodward, F.R.S., exhibited a newly-discovered upper molar tooth of Onohippidium from the cavern near Consuelo Cove, in Last

Hope Inlet, Patagonia. This new specimen was fixed in the bone and bore trace of the soft parts.—Mr. Oldfield Thomas, F.R.S., exhibited and made remarks upon the skin of a female yellow-backed duiker (*Cephalophus sylvicultrix*) which had been obtained in the Awemba district of north-eastern Rhodesia, and presented to the British Museum by Mr. Robert Codrington. This species had previously been known only from West Africa. —Mr. Tegetmeier exhibited the skin of an animal which it had been suggested was a hybrid between a hare and a rabbit, but which proved to be merely a variety of a hare.—Prof. E. B. Poulton, F.R.S., read a paper (illustrated with lantern-slides) by Mr. R. Shelford, curator of the Sarawak Museum, on cases of mimicry amongst Bornean insects and spiders. The author, who had carefully studied this subject in the Malay Archipelago, had made some striking discoveries, and among them were: (1) the well-marked mimetic resemblance of the Mantispidæ to the Hymenoptera; (2) the wonderfully large and complex group of insects of all kinds which mimicked the common dammar bee (*Trigona apicalis*); (3) the large amount of mimicry in longicorn beetles, some resembling Hymenoptera, others Phytophaga, others Lycidæ and others Rhynchophora; (4) the fact that longicorns of the genus Chloridolum and also of some genera of Clytinæ were mimicked by other longicorns; and (5) the re-discovery of the locustid *Condylodera tricondyloides*, formerly described by Westwood from Java, being a splendid mimic of the cicindelid Tricondyla.—A communication was read from Mr. F. H. A. Marshall, describing the variation in the number and arrangement of the male genital apertures in the Norway lobster (*Nephrops norvegicus*), as observed on an examination of a series of 1080 specimens of this crustacean.—A paper was read by Dr. Einar Lönnberg chiefly dealing with the alimentary canal of Trichosurus, Pseudochirus, Phalanger and Petaurus. The varying length of the different sections of the gut and their structure were correlated with the varied food of these marsupials.—A communication from Dr. L. von Lorenz gave an account of the mounted specimen of the quagga (*Equus quagga*) in the Imperial Museum of Natural History at Vienna, and pointed out its differences from other known specimens of this animal.—Mr. J. Lewis Bonhote contributed a paper on a small collection of mammals made by Mr. Th. H. Lyle in Siam. Of the eight species enumerated in the paper, a hare was described as new under the name of *Lepus siamensis*.—A communication from Dr. A. G. Butler contained an account of two collections of Lepidoptera made by Sir H. H. Johnston, K.C.B., in the Uganda Protectorate during the year 1900. The species, of which specimens were contained in the collection, were enumerated, and three of them, viz. *Harma johnstoni*, *Pseudathyma plutonica* and *Aphnaeus hollandi*, were described as new.—Mr. W. L. Distant communicated a paper on the insects of the order Rhynchota collected by Sir H. H. Johnston, K.C.B., in the Uganda Protectorate, in which it was pointed out that the species, of which specimens were contained in the collection, showed marked affinities with the West African forms of these insects.

Entomological Society, January 15.—The sixty-ninth annual meeting, the Rev. Canon Fowler, president, in the chair. —It was announced that the following had been elected officers and council for the session 1902–1903:—President, the Rev. Canon Fowler; treasurer, Mr. Robert McLachlan, F.R.S.; secretaries, Mr. Herbert Goss and Mr. Henry Rowland-Brown; librarian, Mr. George C. Champion; and as other members of council, Mr. R. Adkin, Prof. T. H. Beare, Mr. Arthur J. Chitty, Mr. W. L. Distant, Dr. F. D. Godman, F.R.S., the Rev. Francis D. Morice, Prof. E. B. Poulton, F.R.S., Mr. Edward Saunders, Dr. David Sharp, F.R.S., and Colonel Swinhoe. The president announced that he should appoint Dr. F. DuCane Godman, F.R.S., Prof. E. B. Poulton, F.R.S., and Dr. D. Sharp, F.R.S., as vice-presidents for the session 1902–1903. He then delivered an address in which he dealt chiefly with the question of protective resemblance and mimicry in the case of the Coleoptera, a branch of the subject concerning which but little has been recorded, although mimicry in this order is quite as important as in the case of the Lepidoptera; as a matter of fact, beetles are protected in many ways: by a hard integument, by the assimilation of colour or form to environment, by adopting colours in strong contrast to environment (warning colours), by protective attitudes, by warning attitudes, by warning sounds, by the secretion of distasteful juices or odorous substances, by resemblance to unpleasant substances such as the droppings of birds, by resemblance to well-protected insects other than Coleoptera such as ants, bees and wasps, by imitating other genera and species of the same order which are plainly distasteful. In the course of the address it was pointed out how easily it can be proved that beetles form a large part of the food of birds, as their hard elytra or wing-cases remain for some time entire in their stomachs; in this way it can be proved which species are most liked, and which are disliked or rejected. It is an interesting fact that many of the rapacious birds devour large numbers of beetles, and that a systematic examination of the stomachs of birds proves that the damage done to game is much less than is usually believed, for many of the most persecuted species are mainly or to a very great extent insectivorous; it would be well, therefore, on all grounds, that the indiscriminate slaughter of our few remaining birds of prey should be rigorously discountenanced.

PARIS.

Academy of Sciences, January 20.—M. Bouquet de la Grye in the chair.—On the use of lunar distances at sea, by M. E. Guyou. The method for the determination of the longitude by lunar distances has fallen into disrepute during the last century, and the Bureau des Longitudes has decided that the amount of work required each year for the prediction of lunar distances is out of all proportion to the benefit derived from them by mariners; in the next volume of the *Connaissance des temps*, for 1905, these calculations will accordingly be discontinued. In the present paper a simplified formula is worked out for the case of those navigators who still wish to use this method.—On some properties of fused lime, by M. Henri Moissan. Quicklime, if pure and free from silicate, is melted only in small quantity and with great difficulty at the highest temperature obtainable with the oxy-hydrogen blowpipe; it is, however, melted with great ease in the electric furnace, and with an arc of 1000 amperes first melts and then boils. On cooling, the crystals were found to belong to the cubical system, although after keeping for some months the crystals broke up into others which acted upon polarised light. The density of the lime was raised from 3·3 to 3·4 by fusion. Since lime forms the basis of the electric furnace, it was of importance to study the effect of heating it to high temperatures with various substances. The results of the reactions with carbon, silicon, boron, titanium, chromium, manganese, iron, nickel, cobalt and platinum are given.—The analysis of some antique metallic objects, by M. Berthelot.—On the passage from hermaphrodism to the separation of the sexes by unilateral parasitic castration, by M. Alfred Giard. It appears probable that there exists in the Compositæ parasitic fungi of several kinds. The morphogenic action of these upon their host varies, and the influence of these parasites upon the condition of sexuality of their hosts is equally variable, and furnishes natural experiments of great interest for general biology.—On the conditions to the limits in hydrodynamics, by M. P. Duhem.—On the growth of entire functions, by M. Pierre Boutroux.—Remarks on the preceding communication, by M. Paul Painlevé.—On factorial series, by M. Niels Nielsen.—Coincidences between the elements of the planets, by M. Jean Mascart.—On the application of the Lagrangian equations to electrodynamic and electromagnetic phenomena, by M. Liènard. M. Carvallo, starting with the example of Barlow's wheel, comes to the conclusion that the equations of Lagrange are not always applicable to electrodynamic phenomena, especially in the case of conductors of two or three dimensions. In the present paper it is shown that this restriction is unnecessary and that a rigorous application of the Lagrangian equations gives perfectly exact results in the case of the motion of Barlow's wheel.—Electrodynamics of bodies in motion, by M. E. Carvallo.—Critical constants and molecular complexity of some organic compounds, by MM. Ph. A. Guye and Ed. Mallet. The conclusion is drawn that all the aliphatic nitriles are clearly polymerised, their coefficients of polymerisation being larger than have been hitherto observed.—On some physical properties of hydrogen selenide, by MM. de Forcrand and Fonzes-Diacon. The gas was obtained in a pure state by the action of a little water upon pure aluminium selenide over mercury. Its boiling point under ordiaary pressure was found to be −42° C., its melting point −64° C., and its density in the liquid state 2·12 at −42° C. Its solubility in water was found to be less than has usually been supposed.—Remarks on the oxides of molybdenum, by M. Marcel Guichard.—On the decomposition of acetylene during its combustion, by M. Fernand Gaud. An experimental study into the causes of the choking

up of acetylene burners.—On the tribromo- and triiodo dinaphthoxanthonium and on the hydrobromic, dibromo-, and hydriodic diiodo-ethers of the supposed binaphthylene glycol, by M. R. Fosse.—On the action of the mono-halogen propionic esters upon the sodium derivative of acetyl-acetone, by M. Fr. March.—Contributions to the study of the chemical modifications in plants submitted to the influence of sodium chloride, by MM. E. Charabot and A. Hébert. The addition of common salt to the soil has the following effects: it increases the percentage of organic matter in the plant, and also increases the relative loss of water. At the same time that this double influence is exerted on the plant, the sodium chloride favours esterification and reduces the transformation of menthol into menthane.—The biological theory of vision, by M. Georges Bohn. A criticism of the theory of vision put forward by M. Pizon. Of the three essential ideas of this theory, M. Bohn regards the first as not new and the two latter as not true.—The elementary forms of phosphorus in the invertebrates, by M. Jean Gautrelet. In the blood, carapace and shells of crustacea and molluscs, phosphorus exists in two elementary forms, mineral and organic.—The utilisation of sugars by the organism, by MM. Charrin and Brocard. —On the assimilation of sugar and of alcohol by *Eurotyopsis Gayoni*, by M. P. Mazé. The analytical results quoted would tend to show that the mycelium of this fungus is capable of utilising both alcohol and ammonia without loss of material.—The indications of the prophylaxy and treatment of pulmonary tuberculosis, by MM. Albert Robin and Maurice Binet.—On the origin of certain diseases of chrysanthemums, by M. Chifflot. Two diseases of the chrysanthemum described by M. Joffrin as new have been well known for some time both to botanists and horticulturists.—The siliceous tufa of Côte-aux-Buis, at Grignon, by M. Stanislas Meunier.—On the appearance of lesions in a foal analogous to those produced in its mother by an accident, by M. Le Hello.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 30.

ROYAL SOCIETY, at 4.30.—The Chemical Origins of the Lines in Nova Persei: Sir Norman Lockyer, K.C.B., F.R.S.—The Specific Volumes of Oxygen and Nitrogen Vapour at the Boiling Point of Oxygen: Prof. J. Dewar, F.R.S.—The Distribution of Magnetism as affected by Induced Currents in an Iron Cylinder when rotated in a Magnetic Field: Prof. E. Wilson.

ROYAL INSTITUTION, at 3.—Recent Excavations at Delphi and in the Greek Islands: Dr. A. S. Murray.

FRIDAY, JANUARY 31.

ROYAL INSTITUTION, at 9.—The Ions of Electrolysis: Prof. A. Crum Brown, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Quay-Walls of Keysham Harbour: J. C. Collett and W. H. C. Clay.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Discussion of the Paper by Mr. H. F. L. Orcutt, on Modern Workshop Methods.

MONDAY, FEBRUARY 3.

SOCIETY OF ARTS, at 8.—The Purification and Sterilisation of Water: Dr. Samuel Rideal.

IMPERIAL INSTITUTE, at 8.30.—The Native Races of Nigeria: Dr. C. F. Harford-Battersby.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Explosion of Potassium Chlorate by Heat: Dr. A. Dupré, F.R.S.—The New Table Photometer and Standard Pentane Burner prescribed by the Gas Referees for use in the London Gas-testing Stations: Dr. F. Clowes.

TUESDAY, FEBRUARY 4.

ROYAL INSTITUTION, at 3.—The Cell: its Means of Offence and Defence: Dr. A. Macfadyen.

SOCIETY OF ARTS, at 4.30.—The History of the Rosary in all Countries: Rev. Herbert Thurstan, S.J.

ZOOLOGICAL SOCIETY, at 8.30.—Ecdysis, as Morphological Evidence of the Original Tetradactyle Feathering of the Bird's Fore-limb: Edward Degen. —A Revision of the Amblypodia-Group of the Lycænidæ: G. T. Bethune-Baker.—Notes on the Osteology of *Cogia breviceps*: Prof. W. Blaxland Benham.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Papers to be further discussed*: The Sewerage Systems of Sydney, N.S.W., and its Suburbs: J. Davis.—The Bacterial Treatment of Trades Waste: W. Naylor.

MINERALOGICAL SOCIETY, at 8.—On the Hornsilvers: G. T. Prior and L. J. Spencer.—The Identity of Kilbrickenite with Geocronite: Analyses of Miersite, Marshite and Copper-Pyrites: G. T. RELIGION AS A SCIENTIFIC STUDY.

The Study of Religion. By Morris Jastrow, jun., Ph.D. Contemporary Science Series. Pp. xiv + 451. (London: Walter Scott, 1901.) Price 6s.

PROF. JASTROW is chiefly known on this side of the Atlantic as an exponent of the ancient religion of the Euphrates valley. The work now before us exhibits its author not merely as an Oriental scholar, but as a scholar of wide and original thought, of keen and sympathetic insight. It is a notable book in a series which has included many notable books.

Beginning with an excellent sketch of the history of the study, Prof. Jastrow proceeds to discuss the classification of religions, the various definitions proposed for religion, and, finally, the origin of religion. These form a preliminary division, which is followed by a consideration of special aspects of the study, namely, the relation of religion to ethics, philosophy, mythology, history and culture. Four chapters devoted to certain practical aspects of the study then bring the work to a conclusion.

Anthropological students will naturally turn with the greatest interest to the chapter in which the author discusses the question of origin. They will agree with much of his criticism on the various theories put forward to account for the phenomena which we class together under the name of religion. An original revelation is now everywhere discredited. Modern science and a larger and more sympathetic view of human nature equally reject the crude theories of the philosophers of the eighteenth century. When, however, Prof. Jastrow leaves these behind and reaches Dr. Tylor and Mr. Herbert Spencer, he seems to be confounding in his criticisms two distinct things—the earliest form of religion and the origin of religion. Little consideration is required to show that the earliest form and the origin are not identical conceptions. Either the animistic theory of the former thinker or the ghost-theory of the latter may correctly present the earliest form assumed by religion, and yet the origin of religion itself may remain undiscovered. In other words, there must be behind the earliest form the possibility of life, the inchoate material ready to take shape. Religion is not a simple phenomenon, as the author rightly points out; it is a complex of thought and emotion. What we want to ascertain is what are, reduced to their lowest terms, the components of this complex, and how did they come together to make the germ of that universal characteristic of mankind—religion.

To these questions Prof. Jastrow adopts the answer of Max Müller which ascribes the origin of religion to "the perception of the infinite." Now Max Müller is a very dangerous guide to follow. He knew little of savage belief and savage custom. He derided the efforts of anthropologists to account for myth and custom, whether of the Greeks or of the Hottentots. He himself built up an elaborate system based on a study of the Vedas and philological comparisons. After it had been riddled with shell and rendered completely untenable he was still dwelling in a fool's paradise, despising his antagonists because they were not Sanskrit scholars. And so he continued to the end. One of the last things he did was to publish a reply which exhibited his utter unconsciousness of many of the real problems about religion considered as a human phenomenon. In his solution of the origin of religion as "the perception of the infinite" he was acting like his fellow-countryman in the camel-story. He was evolving the idea of the origin of religion from the depths of his inner consciousness. He had not gone to the nearest representatives accessible to our inquiry of the primitive human being. He had not questioned them. He had not examined their modes of thought, their customs, their beliefs, with the hope of obtaining a clue to those of their hypothetical ancestor. He would no more have thought of doing so than Hobbes or Rousseau. Hence his answer to the question of the origin of religion is not the result of induction, it is "a shot." It is a shot by a very acute and accomplished man, and so perhaps in the right direction. It may miss its mark by excess, rather than by falling short; or by misdirection. But it misses its mark all the same.

The general course of human evolution is upward, not downward. We may therefore assume that the hypothetical ancestor with whom religion originated was a less developed being as to mental and moral characteristics than his descendant, the modern savage. Has any traveller or missionary ever found a modern savage with a perception of the infinite? Perception of the vague, the indefinite, the mysterious, the awful is common to the race; but perception of the infinite is beyond the power of any but the cultivated intellect of a philosopher, if even he can attain to it. Prof. Tiele, whom Prof. Jastrow quotes, tries to avoid the difficulty, while giving the weight of his distinguished authority to the general theory, by speaking of "man's original, unconscious, innate sense of infinity." And Prof. Jastrow himself admits that "such a concept as infinity is a self-contradiction on the part of a finite intellect." Yet he thinks this "need not deter us from according to it a strong influence over primitive man, and all the stronger because of his failure to grasp it clearly." Does the phrase, then, mean anything more from the pen of Prof. Jastrow (whatever Max Müller may have meant by it) than the sense of the mysterious, the awful? If it be simply a pompous way of saying this, it harmonises with what we know of the savage mind and is sufficient to satisfy Prof. Jastrow's own requirements when he says that in seeking for the origin of religion

"we must look for something which could stir [primitive man's] emotions deeply and permanently, which could arouse thoughts that would henceforth never desert him and would prompt him to certain expressions of his emotions and thoughts, so definite and striking as to become part and parcel of family or tribal tradition."

If it mean more than this it goes beyond those requirements and imputes to primitive man powers of thought and ideas incomparably beyond any yet discovered among savage races, while it ignores the practical considerations which must have immediately and profoundly influenced him.

I have dwelt upon this point because it is obviously cardinal in a work on the scientific study of religion.

And I regret that a writer ordinarily so clear-sighted and judicious has been misled by one whose services to the study of Hindu religion and literature can hardly be overrated, and whose contributions to philology and, indeed, the science of religion it would be the veriest ingratitude not to recognise. The rest of my task is more pleasant. To discuss a subject so vast as religion in a little volume of some four hundred pages is no mean undertaking. It cannot be expected that the writer will satisfy his critics on all points. No fulness of treatment would probably enable him to do this, and where so much has to be compressed or entirely passed over it is hopeless to think of it. Besides, the questions dealt with are such that at every point he encounters prejudice and runs the risk of wounding the innermost and most sacred feelings. Among these difficulties Prof. Jastrow has tried to find his way. Owing to his charity and sympathy with the most diverse manifestations of the religious spirit, to his circumspection, to his large views of history and to his dispassionate judgment, he has, on the whole, succeeded admirably. His opening chapter on the history of the study, and those on religion and history and religion and culture, display in full measure all the qualities referred to. The practical suggestions contained in the final section deserve careful consideration. In the chapter on the study of the sources the standard is fixed very high. It is well that it should be so. But it is to be observed that the exhaustive study demanded for the religion to which the student proposes to dedicate himself will, in the case of most students, leave but little time for that acquaintance which the writer demands, and rightly demands, with other religions.

"In order to understand one religion," he says, "we must be acquainted with more than one. Religions with literatures differ far more from one another than those which possess none. Hence it is not sufficient to study merely one religion direct from the sources."

By this expression the author means the study of the religious literature in the original tongue. He does not mention, though his illustration of the Hebrew word *goel* evidently implies, a study of the history and culture of the people concerned outside their religion. To continue the quotation :—

"Studying two in this way may be set down as a minimum for acquiring that firmness of method and keenness of judgment needed for the chief problem of religious research—the interpretation of facts. This does not imply that the two are to be cultivated with equal intensity, or that the entire field of both must be covered, but only that in addition to the one religion which forms one's special object of research, one should be able to acquire a sufficient knowledge of a second religion, direct from its sources, as to be able to penetrate into the spirit of that religion."

The ideal is excellent. And yet I am not sure that a more important service may not sometimes be rendered to the study of a religion by one who is ignorant even of the original language, if he be able to bring to bear upon a study of first-rate translations a wide ethnographical knowledge, and therefore to compare the practices of totally different races and cultures. How, for example, would a study of the sources of Hebrew and Egyptian religions, or Hebrew and Hindu religions, even if we add Mohammedanism and Zoroastrianism, enable us to solve the origin and meaning of the rite of circumcision? Robertson Smith could never have written his "Religion of the Semites" if he had been *simply* a student, from the sources, of the Hebrew and Arab religions. A general acquaintance with the results of anthropological study of savage peoples was of more value to him than the study of the literatures of half-a-dozen civilised religions would have been.

I have no space to do more than refer to the cogent arguments with which the author enforces the need for the scientific study of religion in higher education generally, and especially in mission-colleges, or to his exposition of the utility of museums in the study. These chapters, not less than the earlier parts of the book, deserve to be carefully read. The appendices illustrate them by showing actual courses of lectures delivered at the École des Hautes Études at Paris, and the arrangement of the Musée Guimet, which was specially formed to aid the study of religion. To guide the student, a bibliography is added of a remarkably catholic character.

E. SIDNEY HARTLAND.

CHEMISTRY FOR COLLEGES.

A College Text-Book of Chemistry. By Ira Remsen. Pp. xx + 689. (London: Macmillan and Co., Ltd., 1901.) Price 8*s.* 6*d.* net.

THIS book is intended to fill a place between the "Introduction to the Study of Chemistry" and the "Inorganic Chemistry" by the same author. The style and plan of the book may be estimated from the author's remark in the preface, where he expresses the opinion that "The time has not yet come for the abandonment of the study of elements and their compounds in what some are pleased to call the old-fashioned way." Intended, as its name implies, for the use of colleges, the book differs in no essential particulars from other text-books of the same scope. The arrangement adopted for the treatment of the subject is one that has in more recent years repeatedly appeared, a few typical elements and their compounds being studied in some detail in the earlier chapters, and the main bulk of the subject subsequently dealt with from the standpoint of the periodic law. Each descriptive chapter is followed by a number of experiments to be carried out by the student, whose power of observation is aided and developed by the manner in which many suggestive questions are asked concerning each experiment. A number of chapters throughout the book are devoted to a discussion of the principles of theoretical chemistry, and it is in reading these that we are more particularly struck with the loose and inaccurate expressions that are more or less characteristic of the book. Thus it is not the best definition of energy to say that it is "that which causes change in matter." Again, in discussing chemical changes, the student is told to "consider the changes included under the head of fire." Is not fire rather a phenomenon accompanying these changes? In discussing the law of conservation of energy the incomplete statement is made that "from a certain amount of heat we can get a certain amount of motion, and that for a

certain amount of motion we can get a certain amount of heat." In the first place this form of statement is likely to give the impression that heat is something entirely different from motion, and in the second place it implies that heat and motion are quantitatively convertible, which is not strictly true. Further on the statement is made that in order to bring about chemical change "high heat must be used to aid the reaction."

A great number of similar expressions are to be found scattered throughout the book, and it seems a very short-sighted policy to sacrifice accuracy and the use of scientific modes of expression, even in attempting to make matters more intelligible to beginners, as it is far more difficult to get rid of early false impressions than to acquire correct ones in the first place. This sort of treatment is especially to be noticed in the author's account of the ionic theory. On p. 90, ions are first introduced very briefly to the notice of the student, and throughout the succeeding pages many reactions are represented as due to action between the ions; and equations are printed in which the ions are represented as atoms. This must be exceedingly confusing to the student who has been told in another place that atoms, generally speaking, cannot exist in the free state; and it is not until p. 417 that this difficulty is overcome for the student by the true explanation of the nature of an ion. Another serious misstatement occurs in the account of the phenomena of osmotic pressure, where, after quoting the extension of Avogadro's law to solutions, the following passage appears: "Notwithstanding the simplicity of this law, no practical method for determining molecular weight based upon it has yet been devised."

The more descriptive part of the book is also not free from inaccuracies. For example, in one portion of the table on p. 15 the atomic weights are referred to $H=1$, in another part of the same table to $O=16$. The term combining weight is itself used in two different senses in different parts of the book; in the earlier portion it is used as synonymous with atomic weight, and in the later portion as a simple submultiple of the latter. Another discrepancy is that which ascribes to krypton on p. 19 the atomic weight 81·8 and on p. 262 58·67. It is disappointing to find the author of so excellent a work as the admirable little book on organic chemistry failing to come up to the standard of accuracy which is now demanded of teachers.

HYDRAULICS.

A Treatise on Hydraulics. By Henry T. Bovey, M.Inst.C.E. Second edition, rewritten. Pp. xviii + 583. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1901.)

THE author of this treatise, in his position of professor of civil engineering and applied mechanics at McGill University, Montreal, has exceptional opportunities for conducting experimental investigations on the flow of water, owing to the remarkably complete equipment of the hydraulic laboratory under his charge, which the University owes, in addition to many other endowments, to the munificent liberality of Sir William C. McDonald, a well-known merchant residing in Montreal. It is very satisfactory to note that Prof. Bovey has made full use of his opportunities in advancing the study of hydraulics, as indicated, in the first instance, by the publication of the first edition of this book in 1895; whilst this second edition, with its rearrangement, its large quantity of new matter, and its additional tables of experimental results, marks the progress which has been made in the interval towards raising the subject of hydraulics, so long based on empirical formulæ, into the position of an exact science.

The subject is divided into eight chapters, to each of which, in addition to examples worked out in the text, is appended a number of problems for the student, relating to the questions dealt with in the chapter, together with their answers. The book begins with a chapter on general principles and the flow through orifices and over weirs, followed by one on fluid-friction and pipe-flow, and another on the flow of water in open channels; and these three chapters, each extending over more than a hundred pages, complete the portion relating to the flow of water, and occupy more than half the book. They furnish a fairly exhaustive treatment of the subject; but though, owing to the large print, the widely-spaced formulæ, the numerous diagrams, and the tables, the actual contents of these chapters are not so great as might be inferred from the number of pages they occupy, the chapters are inconveniently long, and might with advantage have been subdivided. This is undoubtedly the portion of the book to which civil engineers engaged in water-works, irrigation, and river improvement will mainly refer for an elucidation of the difficulties involved in the correct determination of the flow of water through orifices, over weirs, along pipes, and in open channels. A chapter is devoted to the important subject of hydraulic machinery, including rams, presses, accumulators, and water-pressure engines. Three chapters relate to water-motors, dealing successively with impact, reaction, and the principles of impact and tangential turbines, vertical water-wheels, and turbines; and the final chapter deals with centrifugal pumps. The book is illustrated by three hundred and thirty figures in the text, mainly diagrams for elucidating the various theories and principles dealt with, together with a few drawings of machines referred to; whilst a very convenient paged list of the various headings of subjects throughout the book is given in the table of contents at the commencement, and a concise but useful index concludes the volume.

The mathematical treatment adopted right through, with the four hundred and forty-six examples given for working out, render the book more especially suitable for students in hydraulics who have had a previous mathematical training, the book having, indeed, been originally the outcome of a series of lectures to such students; and it will be doubtless of interest to hydraulicians, particularly in view of the advance it manifests in hydraulic science. A less elaborate and less educational method would probably have more favourably commended the book to the notice of practical engineers interested in hydraulic problems; and, in its present shape, the book seems likely, irrespective of its value to hydraulic students, to be mainly advantageous to those engineers

in practice who possess adequate mathematical knowledge and leisure to select from the numerous formulæ, and especially from the tables, those portions which are best adapted for practical application. It appears really almost impossible to produce a treatise on such a subject as hydraulics, so that, whilst furnishing an exhaustive treatment of the subject and being of considerable educational value for the advanced mathematical student, this book should, according to the author's hopes, at the same time prove specially adapted to the requirements of busy practical engineers; for in proportion as it realises its main object, it tends to become unsuited for its secondary purpose. Nevertheless, as a book tending largely to advance the science of hydraulics and promote the thorough training of future hydraulic engineers, it deserves to be very cordially welcomed.

OUR BOOK SHELF.

Erlebtes und Erstrebtes. Von Carl Gegenbaur. Mit einem Bildniss des Verfassers. Pp. 114. (Leipzig: Wilhelm Engelmann, 1901.) Price 2*s.*

THERE must be many who have hailed with delight the announcement of "Erlebtes und Erstrebtes," the authentic account of the long and assiduous life of the founder and elaborator of modern comparative anatomy. However, the readers of the little brochure will be sadly disappointed, since it contains not much Erlebtes, and the author is more than reluctant about telling us what he has "Erstrebt," *i.e.* striven for and reached. Most of the reminiscences can be of interest only to his own family. Born at Würzburg August 21, 1826, sprung from a family of mostly Governmental officials, mainly of Bavarian descent, Gegenbaur went through his schooling at Würzburg and spent the vacations roaming about with his gun, dissecting his spoil. He is emphatic about the value of the studies of the classics; "to ignore the classical languages means to resign part of our education, and those who say that these languages are dead, ought to remember that the letter killeth, but the spirit giveth life." Würzburg was also his university, where, after eighteen months of preliminary philosophical and historical studies, he was inscribed as a medical student. In the same year, 1847, Albert Koelliker was called to the university. F. Leydig was privat docent for microscopical anatomy, and for him our author has high praise. Another of his teachers was R. Virchow, "whose great merit is that he gave a new, very fertile, direction not only to pathology, but to the whole of anatomy, by imparting to it the notion of evolution."

Gegenbaur studied with a view to following natural sciences, not to devote himself to medicine, which latter he could not bring himself to consider a true science. Still, he became third assistant at the Julius hospital. In 1851 he took his degree, one of his theses dealing with the changes and variations of plants. Then followed his "Wanderjahre," visits to the chief German towns, and in Berlin he made the personal acquaintance of Joh. Mueller. In 1852 he went with Koelliker and Heinrich Mueller, of retina renown, to Messina, bent upon zoological research, and he wandered through Sicily, in which island he spent nearly a year.

In 1854 Gegenbaur established himself as privat docent for zoology at Würzburg, soon to leave this place for Jena as professor extraordinarius. At the death of Huschke he became the latter's successor as professor of anatomy. This was the first university in which henceforth anatomy was separated from physiology, a science for which he has not many kind words to say. Berlin followed suit in the same direction after the decease of Joh. Mueller, then Würzburg, &c.

In 1856 he married his first wife, whom he was to lose soon after; we are not told that she was a daughter of Huschke. From this time dates the intimate friendship with Haeckel. The author speaks with warmth of quiet little Jena as the place where practically all his fundamental ideas were conceived and grew. He set himself to rescue anatomy from the state of mere description; the term morphology in opposition to physiology "was intended mainly to express the difference of treatment," and anatomy itself was to be elevated to a higher position by the comparative method.

In 1873 Gegenbaur went to Heidelberg as the successor of Fr. Arnold, his second father-in-law. The following twenty-nine years, so full of activity and world-wide influence, are dealt with in ten small pages—the writing of the text-book of the anatomy of man (now in its seventh edition), based upon the results of comparative anatomy; the starting of the long series of the "Morphologische Jahrbuch," and scanty reminiscences concerning, and of interest to, but a few intimate friends.

The book is prefaced with an excellent likeness of the author.

H. G.

Beautiful Birds. By Edmund Selous. Pp. ix + 224. (London: Dent and Co., 1901.)

MR. SELOUS' volume, in spite of its pleasant-looking green cover, numerous though indifferent plates, and text cheerfully varied with italics, is in reality no more than an unduly swollen tract. It is necessary to say this at once, and with emphasis, lest the unwary buyer of bird books should add this volume to his library under the impression that he was adding a useful and chatty account of humming-birds and birds of paradise. The volume is, in fact, an example of what is known in the animal world as "aggressive mimicry." Under the guise of a pleasing discourse upon some of the more striking among many beautiful birds, the author really provides the public with not much more than a simple attack upon the wearing of birds' plumes by ladies. We have not the least objection to Mr. Selous' views in this matter, or to the expression of them. But he might surely have found one of those numerous journals which delight in denunciatory declamation rather than in adherence to frigid fact, and into its sympathetic columns have poured his feelings of horror at feminine inhumanity. Then no one would have been deceived about the matter, as some possibly may be. Mr. Selous builds upon a minimum of zoological fact a large superstructure of curiously agitated, almost hysterical, ethics. The book is, in its form, addressed to a hypothetical and female infant of tender years who is urged to persecute her mother and female relatives generally until they promise never to wear birds' feathers in their hats, as, for instance—"You must remind her of it from time to time ('remember mother you promised'), when you hear her talking about getting a new hat. And when you have made her promise about herself then you must make her promise never to let you wear a hat of that sort. . . . And if you have a sister very much older than yourself, &c., &c." With such observations the chapters are liberally sown and nearly invariably conclude; it is, moreover, at least once added that the mother and sisters in question had better read this particular volume. We sincerely hope that they won't take this broad and business-like hint; for even from the point of view of a "humanitarian" (we must use inverted commas as there is no necessary connection between the use and meaning of this term) Mr. Selous is unworthy of praise. Why should he select the "beautiful birds" only, and by implication condone the massacre of birds that have not that advantage?

F. E. B.

Lehrbuch der Chemie und Mineralogie. By Prof. G. Siebert. 3 vols. Pp. viii + 101, vi + 144, vi + 110; figs. 100, 91, 32. (Braunschweig: Friedrich Vieweg und Sohn, 1901.) Price Mk. 4·25.

THIS text-book, which is intended for use in higher schools, does not differ to any very remarkable extent from numerous other elementary treatises on the same subject. Perhaps the first volume, described as an introduction to chemistry and mineralogy, shows the most originality in treatment. In this part the beginner is made acquainted with the most important chemical processes, such as oxidation and reduction, and is taught something of the more common chemical compounds, mainly by means of experiments, of which a hundred are fully described. These experiments are in most cases quantitative, and involve the weighing of gases as well as of solids and liquids. The laws of chemical combination which receive their expression in the atomic theory are thus impressed on the student by his own actual quantitative results. The treatment of the mineralogy is of a somewhat perfunctory character. The six systems of crystals receive the usual brief and inadequate exposition common to chemical text-books, and the Naumann system of notation for the crystal-faces is explained, but no mention is made of Miller's system. A review of the most important minerals appears at the end of the volume, and brief descriptions, with figures of the crystals, of natural phosphates, sulphates, &c., are given in their appropriate places in the text. The second volume is devoted to inorganic chemistry, and the elements with their principal compounds are treated in turn, the non-metals in the order of their valencies, and the metals in the usual groups. The third part deals with organic chemistry. Structural formulæ are explained, but the treatment is sufficiently elementary, as is evident from the fact that the whole subject of both fatty and aromatic compounds occupies less than a hundred pages. In an appendix are given the descriptions of a number of simple experiments illustrating the methods of production and properties of some of the most important organic compounds. A very brief introduction to organic and volumetric analysis completes the volume.

Knowledge. Vol. xxiv., January to December, 1901. Pp. xii + 288. (London: *Knowledge* Office.) Price 8*s.* 6*d.*

SOME of the full-page photographic plates in this volume of *Knowledge* are very fine. Among the subjects are several brilliant photographs of star clusters and nebulæ, taken by Dr. Isaac Roberts, constellation figures on Greek coins, lunar photographs, life-history of a sun-spot group, spectra of Nova Persei, and the solar corona of May 18, 1901. Mr. E. W. Maunder has a series of articles on constellation studies, in which he deals largely with the poetical aspects of the sky; Dr. Vaughan Cornish has four articles on the sizes of ocean waves; Mr. G. H. Carpenter describes insects of the sea; Mr. R. Lydekker writes on a number of subjects of zoological interest; Mr. H. F. Witherby on ornithological experiences in the Soudan; and Mr. R. Lloyd Praeger on flowering plants. There are numerous other articles of an instructive character.

A Geography of Wales. By A. E. L. Hudson, B.A. Pp. xii + 164. (London: Macmillan and Co., Ltd., 1902.)

THIS book is intended chiefly for use in Welsh schools, and the general idea borne in mind in its preparation is that the best foundation for a knowledge of geography is the study of the land and the people of the district and country in which the pupils live. The attention given to physical geography and to civic affairs, such as local and national government, and population and its distribution, is noteworthy. There are many attractive illustrations, which, with the instructive text, will serve to commend the book to the attention of teachers.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Fall of Mud or Dust.

MY men here noticed on Thursday last the 23rd inst. that the leaves, glasses of the frames and iron work of the gates were smeared with a reddish mud; one hedge in particular they described as almost covered with the substance; and the pinafores of a cottager's children which were hanging out to dry were so stained with the deposit that they had to be rewashed. When the substance fell no one here knows, nor is it clear whether it fell as dust or mud; from the firm way in which it has attached itself to the iron work I should think that it fell as mud.

Unfortunately, I did not hear of the event till some days afterwards, and I first saw the deposit yesterday. It was still, notwithstanding a good deal of rain, to be seen on the iron work, the glasses of the frames and on leaves. I send for your inspection herewith a laurel leaf, down the sides of the midrib of which you will find some of the deposit in question. Possibly some expert may be able to determine the nature of the deposit. It does not appear to me to be silica.

I append cuttings from local papers, showing that the phenomenon was observed elsewhere. Lawrence Weston is some five miles north-east from hence, Chewton Priory some fifteen miles south-east, and Barry Island some twenty miles west-by-south and on the other side of the Bristol Channel.

Failand, January 28. EDW. FRY.

From the *Bristol Times and Mirror*, January 21.

A CURIOUS STORM.

SIR,—I thought the readers of your valuable paper would be interested to know that on Thursday morning we had what I think a rather strange storm, about a quarter past seven, of about 15 minutes' duration. After it got light I found quite a covering of dust on the glass on the garden frames, about the colour of Bath brick dust. Not having seen any account of it in your paper, I thought I should like to hear if anyone else had noticed it. Yours truly,

Lawrence Weston, Henbury, January 24. A. DENHAM.

From the *Western Daily Press*, January 28.

SINGULAR PHENOMENON.

SIR,—Seeing in your paper of yesterday's date a paragraph about a mysterious red substance which fell at Barry Island on Wednesday last, I write to say that a somewhat similar phenomenon occurred here.

Wednesday the 22nd was with us very warm, with wet mist only measuring 0·02 of rain. Afterwards the glass and wood-work of the greenhouses and frames were covered with a rust-coloured dust, which has left stains on the paint.

Yours faithfully,

Chewton Priory, Bath, January 26. WALDEGRAVE.

Change of Pitch of Sound with Distance.

I HAVE read with considerable interest the letter by Mr. Paul R. Heyl on this subject in your issue for January 23. Speaking off-hand, I should have agreed with Mr. West, that pitch rises with distance; but, in view of the experience of your later correspondent's grandfather, I am inclined to adopt the contrary view. Many years ago I was sitting with an organist friend listening to a fugue on an organ—I think the player was the late Mr. Thomas Adams, and the fugue one of the immortal "Forty-eight" of Bach. At any rate, it was in a minor key; but I noticed that the last chord was *major*. "Why," I asked my friend, "does he end with a major chord?" "Because," was the reply, "sound has a tendency to rise in a long building like a church, and therefore the writer anticipated this by writing his final chord with a major third." But was this the reason? If the late Mr. Knauff was right, it was probably to allow for the third dropping, and the chord reaching the listeners as a minor chord, in keeping with the rest of the piece.

Of course, everybody knows that the practice above alluded to of ending a minor piece with a major chord is by no means uncommon with Bach. For example, in his "Grosse-Passions-Musik," the chorus which follows the duet, "My Saviour Jesus now is taken," ends (according to the English version by Miss Johnston) with the words, "the treach'rous betrayer, the murderous throng." Bach has reiterated them—the first time with a minor chord (E), with G natural, on the word "throng"; the second time with a chord on the same key-note, but with a *major* third (G sharp) and a pause. The effect is thrilling. Surely there could have been no allowance for drop here. Handel, on the contrary, begins and ends his chorus, "And He shall purify," in the "Messiah," in G minor, although the two succeeding pieces are in D major, with which key the previous piece would have been brought into relationship by the raising of the third.

This is a digression from the subject of your correspondents' letters, which probably never entered the minds of the great masters named. R. FREEMAN.

London, February 3.

A Lunar Romance.

IS not Mr. Wells right in the description of the effect referred to by the reviewer of his "First Men in the Moon" (p. 218)? The *sphere* itself, as a whole, is *not* attracted by gravity. The action of gravity has effect only in the line (?) through the open window, and, *quâ* the sphere, would only affect that part which would be directly in a straight line from the moon through the window. F. C. CONSTABLE.

Wick Court, near Bristol.

IN answer to Mr. Constable, I think we cannot allow that the sphere is not attracted by gravity. I understand it to be a sphere of solid glass, PQ, inside a cavorite covering, RS (Fig. 1).

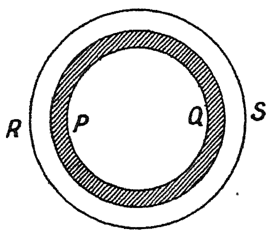

Fig. 1.

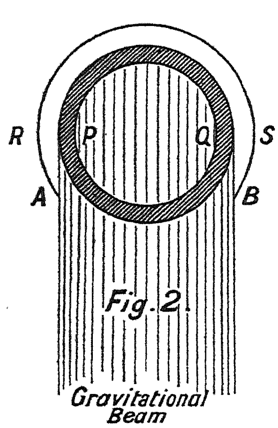
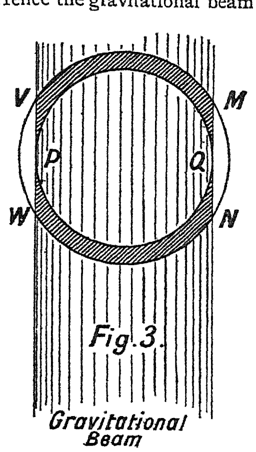
In the case considered, the covering is removed through a wide angle AB, thus described (p. 62): "Four windows were open in order that the gravitation of the moon might act upon all the substances in our sphere." Hence the gravitational beam





reaches the whole of the glass sphere itself (Fig. 2); unless (Fig. 3) Mr. Wells means to reserve little pieces, VW and MN, at the sides outside the beam. In this case the total mass of the sphere remains the same, but is not all acted on by gravity; so that the acceleration of the whole would be *less* than *g* (in the ratio of mass acted on to total mass), *i.e.* less than that of objects within, which would promptly settle to the "floor."

If Mr. Wells was thinking in this subtle fashion I withdraw my criticism, and Mr. Constable will see that I have left an open door for myself in the review for withdrawal. I may say it was left open expressly in view of this possibility. But the context does not suit this view at all well.

THE REVIEWER.

Cherry Leaf Disease.

THE question raised by Sir W. T. Thiselton-Dyer's letter is a very important one, and I venture to offer a few observations on it.

It is impossible that Mr. Bennett—still more Mr. Carruthers—could have intended to suggest that the experts at Kew and the British Museum are not competent to investigate such diseases as the above when they are submitted to them. They probably meant that an organised system is wanted in every county, by means of which an outbreak of any such disease should be at once brought under their notice. This could only be satisfactorily done by local inspectors, who would be in touch with the farmers on the one hand and the experts on the other. It should be part of their duties to keep accurate records of temperature and rainfall in order to show the connection, if possible, between these and the disease. These officials would naturally be appointed and paid by the County Council.

As regards the outbreak of Gnomonia mentioned by Sir W. T. Thiselton-Dyer, it is a curious fact that in most of the orchards about here affected by it in 1900 the disease has almost disappeared, though no preventive measures such as stripping the leaves were taken. It would, however, be very unfair to blame the advisers of the Royal Agricultural Society for raising a false alarm; in the case of a disease not known to have occurred in this country before, they were clearly bound to act upon the best information they could get—that of Frank—and warn the farmers. The more equable climate of England, as compared with Germany, is probably the cause of the different result, the effects of comparatively small differences of temperature and moisture being vastly more important than is generally believed.

ALFRED O. WALKER.

Ulcombe Place, near Maidstone, February 2.

Extremes of Climate in the British Empire.

YOUR correspondent (p. 299) who writes under this head in the current number of NATURE would make the labours of an editor as super-Herculean as those of the Highland minister who was called upon to incorporate the whole body of divinity in every sermon lest his flock should be misled.

That it would be wrong to generalise on the climates of the British Empire from eighteen stations, or to claim any one of them as the hottest or the wettest point, is obvious; but even in the few lines of your abstract you have not done this, and in my original summary (*Symons's Meteorological Magazine*, November, 1901, p. 167) I said:—

"It is true that neither the hottest, the coldest, the wettest nor the driest points in the Empire are dealt with; and the reader is warned, as on each previous occasion of presenting this annual summary, not to take the figures as meaning more than they profess to convey."

In order to secure continuity in the records, which are published monthly, it is necessary to obtain them from regular observatories: these are, unfortunately, few; but, fortunately for the student of climatology, they are usually situated in districts of normal rather than of extreme climate. Additional observations would certainly be welcome, and I hope during the present year to be able to publish monthly records from at least twenty-five stations in all the Britains.

HUGH ROBERT MILL.

Elementary School Mathematics.

IN connection with the present discussion on the teaching of elementary mathematics in schools, and the recommendation made by many experienced teachers that much use should be made in geometry—at any rate in the earlier stages of actual

measurements of lengths of lines, may I suggest that such measurements should always be made in centimetres? A handy steel rule, six inches long, graduated both in inches and tenths, and in centimetres and millimetres, can be bought for a few pence, and is easily carried in that almost omnivorous receptacle—the pocket of a schoolboy. The use of such a rule would beget familiarity with the metric scale, in itself an advantage for any boy whose education includes some knowledge of elementary physics. But more—the schools of the country would soon be sending out each year a body of educated men acquainted more or less with the advantages of the metric system, and their influence can scarcely fail to be helpful in hastening the general adoption of the metric system—a change so much to be desired both in education and in practical life.

Fettes College, Edinburgh. JOHN S. YEO.

Electrification of Glass.

REFERENCE is commonly made, in text-books of electricity, to the uncertainty of kind of the electrification produced on glass when it is rubbed with fur or flannel, opposite results being obtained with different specimens.

The following is a variation which I have not seen mentioned. A strong positive charge may be given to a smooth rod of soda-glass, by rubbing it gently with a certain piece of fur. Vigorous rubbing, on the other hand, produces an equally good negative electrification. Thus the two sorts may be produced in quantity at one stroke, by making the friction small at first and finishing with a vigorous pull. The half-way region of zero electrification may be displaced at will.

A piece of lead glass seems to be always positively electrified by this particular piece of fur. F. HODSON.

North Eastern County School, Barnard Castle, January 28.

THE DANGEROUS SIDE OF INDIA.[1]

AT the present time much interest attaches to the North-West Frontier of India, and to Afghanistan, the Beluch country and the Persian Gulf. Sir Thomas Holdich's book, therefore, is opportune as well as of remarkable value. It must be carefully studied by everyone desirous of forming an intelligent opinion about our Indian frontier policy. The politician, the military expert, the dilettante student, the thoughtful citizen of the Empire, all will gain much from its well-written pages. Moreover, although the chief and permanent value of this admirable work is topographical, the general reader merely in search of mental enjoyment will find a peculiar pleasure in the vivid descriptions of stirring incident and picturesque countries. The style is always easy and graceful, while it rises frequently to singular eloquence and poetry. Rarely are sound knowledge and expert opinions offered to the public in a form at once so simple and attractive.

A cultured survey officer of the Indian Service has clearly very enviable opportunities for varied experiences; but it requires a quiet observant mind, sanitary with humour, to vitalise scenes and peoples as they appear in this record of twenty years' work on the restless Indian frontier. Of the various districts and wild folk shown to us, some are more especially in one's thoughts at the present moment. The political temperature of parts of the Punjab frontier is just now simmering or even ebullient. In Swat there is the outward aspect of peace without cheerfulness. How much this is due to the dominance of our big battalions in that historic valley and how much it is due to the vast number of strong fighting men, fierce of heart and light of foot, who were killed there during the 1897-98 uprising it is hard to decide. No one, however, seems to assert that the people like our presence among them. When the sullen youths shall be grown enough to strike another blow for Islam, we may expect more trouble in that sickly district, especially if the garrison is diminished. The less fanatical Orakzais and Afridis sit complacent, but watchful. Satisfied with their last display of fighting prowess, they are ready, on the instant, to rush to the rally if their freedom of rascality is threatened or their subsidies are reduced. Further south, in Waziristan, we have gone back to the old plan, the ancient way, of surprise and counter raid, the burning of homestead and tower. Also in the organisation of the new frontier province, of which so much has been written, Lord Curzon has reverted to more primitive methods. Complex forms of administration have been replaced by a rougher, not necessarily less efficient system. The mere lawyer and the pleader are beggared in importance, and the "political officer," raised aloft in power, is to be mantled with responsibility. It is admittedly a putting back of the clock. Curious, not always friendly, eyes watch the experiment. Its success mainly depends upon the attractions dangled before the eyes of able officials to draw them from easier days, and domestic joys, to rugged solitary work in desolate places. Beluchistan is placid and peaceful. It is the more primitive type of frontier management. To this simple pattern the new frontier province is to be retrograded by the forcible suppression of many functions and recent developments, which until now were gloried in as triumphs of British rule in India. But not only are the political and ethnological conditions of Beluchistan and the new frontier province dissimilar, but a Sir Robert Sandeman is not the product of every day.

Then behind all these borderland experiments stands dubious Afghanistan watching curiously its new Amir, full of conjecture, moreover, about the refugee pretender in the hands of the Russians, and that other refugee pretender, the honoured guest of the British at Rawalpindi. It is no easy task to rule the turbulent, faithless Afghan tribes, and the peaceful succession of the present ruler of Kabul may be followed at any moment by some wild upheaval of ambition or of revenge on the son for the savage repressions of his father. Herat, and the Russians peering wistfully at that coveted if somewhat corroded "Key of India," must always be of anxious interest to all students of the Afghan frontier and to all lovers of peace.

To understand the real value to India of all these differing countries, and to estimate accurately their relative importance, a thorough comprehension of Sir Thomas Holdich's facts and geographical opinions is an essential precedent condition. He has something important to say on all the pressing questions concerning the north-west limits of India, some solid physical basis to disclose or to explain, ignorance of which must make reasonable conclusions impossible. That strange diplomatic instrument the "Durand" treaty has a chapter to itself. Surely no more curious or less sincere arrangement was ever concluded between the Government of India and an adjoining Power. By it a definite frontier line has been laid down and actually demarcated. On one side of this line the Amir is to maintain order and never again to throw covetous glances beyond the boundary pillars which define its course. We, on our part, accept responsibility for all the independent tribes which intervene between the pillars and our Punjab territory. The Amir can fulfil his promises, while obviously we can only keep to our agreement by first subjugating this wild mountain land. Misdemeanours against Afghanistan by the tribes nominally under our responsibility, but actually uncontrolled by us, can only be punished by the Amir sending raiding parties into the very country he has promised not to enter. We have to wink at these flagrant violations of a solemn treaty because we ourselves never had any intention of obeying its terms.

Such loose acceptances of frontier responsibility are,

[1] "The Indian Borderland, 1880-1900." By Colonel Sir T. Hungerford Holdich, K.C.I.E., C.B., F.S.A., late of the Indian Survey Department. Pp. xii + 397. (London: Methuen and Co., 1901.)

in a political sense, immoral as well as practically mischievous. Already terrible evils have followed. The independent tribes, on our side of the limit, believe that in 1893 we annexed their hills, and only now refrain from a military occupation because of the martial prowess of the clansmen. All the frontier wars and the exacerbation of fanaticism all along the line since 1893 are traceable directly or indirectly to this unlucky treaty. Implacable suspicion and armed watchfulness on the part of the highlanders, as well as those violent outbreaks which have cost us so dearly, are part of the price which we have already paid for a false policy, not justified even by the seeming expediency of a critical time.

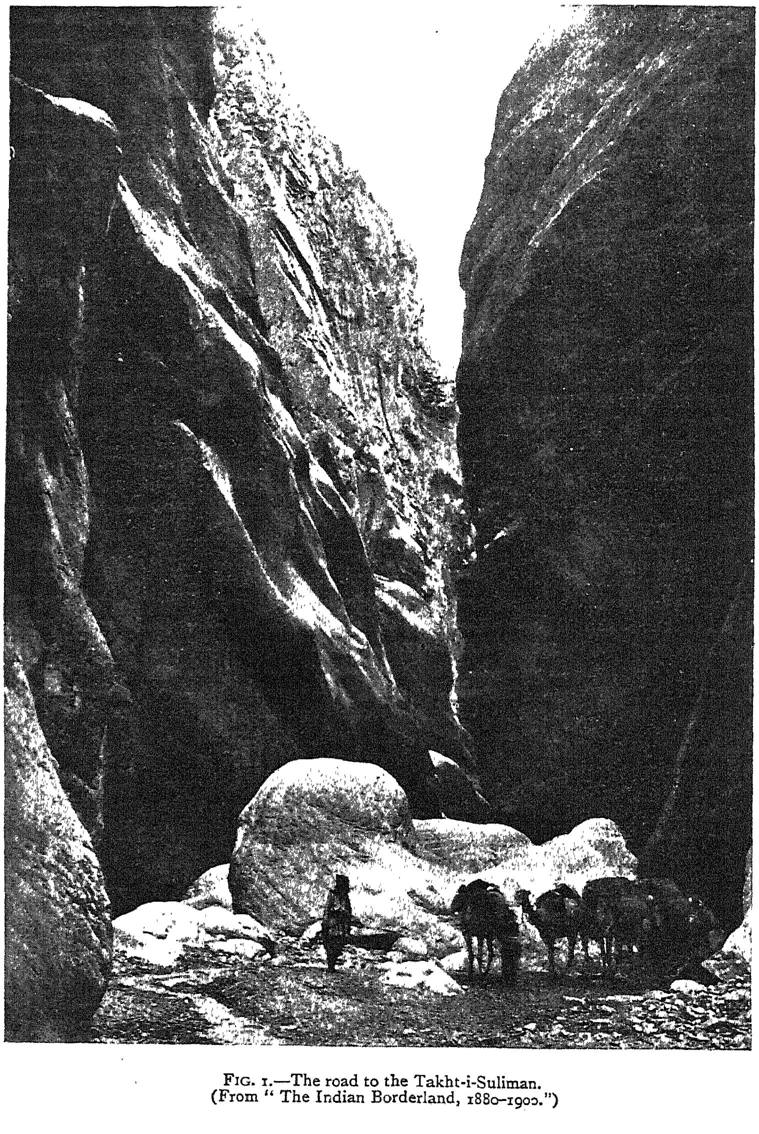

FIG. 1.—The road to the Takht-i-Suliman. (From "The Indian Borderland, 1880–1900.")

Of Makran, the Persian Gulf, and that place of contention, Koweit, Sir Thomas Holdich has very pleasant and instructive pages. Quite apart from the "professional" value of his judgments and his historical summaries, there is a graphic power in his descriptions which stamps the strange scenes deeply in the mind. Here, as in all his other wanderings, this genial, able Royal Engineer officer displays his love of nature's beauty. This makes his book, not only the most important publication of the time on the Indian frontier, but also the most agreeable to read. The illustrations are excellent, the map trustworthy and very useful.

REPORT OF THE INDIAN PLAGUE COMMISSION.

THIS report, consisting of five big volumes, is a record of the work of the Commission appointed by the Governor-General in Council, with the approval of the Secretary of State for India. The questions submitted to the Commission were four: (1) the origin of the different outbreaks of plague (in India); (2) the manner in which the disease is communicated; (3) the effects of curative serum; and (4) the effects of preventive inoculation.

The Commission, with Prof. Fraser, F.R.S., as president, has collected in seventy meetings in different parts of India and in two additional meetings after their return in London, the stupendous amount of evidence embodied in three closely-printed large volumes in twenty-seven thousand questions and answers.

The summary of the conclusions arrived at by the Commission, after having examined a host of competent witnesses and after having carried out itself or directed a considerable amount of work concerning plague, is contained in vol. v. on more than 500 folio pages. From this it will be understood that the work of the Commission was carried out in a thorough manner. Add to this the fact that the Commission had prepared a large amount of work in the form of charts, tables, statistical summaries, &c., and that after repeated and lengthy discussions amongst themselves the commissioners remained divided on several important points. We mention this to prepare the reader of the report for the surprise of not finding specific answers to the specific questions put to the Commission. This surprise is to a certain extent justified if we remember that various foreign commissions—Russian, German, Austrian, French—who have been sent out to India or Oporto respectively to study plague have in their reports given their Governments to understand that they have satisfactorily solved all and every problem concerning every point of the disease plague.

One has only to look through vol. v. of the report to feel convinced that the Commission has striven assiduously to find the specific answers; every page of this volume testifies to the desire to arrive at the correct conclusion; every assertion of fact brought before it was judicially and critically examined, compared and adjusted to its proper place and bearing. There can be, therefore, no question as to the thoroughness of the work itself. The cause of the deficiency of the answers must be sought elsewhere. In looking at the evidence of the witnesses and at the observations of

the commissioners themselves, it will be seen that the answers were not found, partly because the data to hand were insufficient and partly because the problem of plague in India is of far greater complexity than we were led to expect, and because there were too many unexpected difficulties encountered by the Commission.

If one reads some of the self-sufficient conclusions of some modern writers on plague (including the above-mentioned reports of the foreign commissions), one is met by the apparent simplicity and seemingly satisfactory solution of the problem concerning the etiology, epidemiology, prophylaxis, treatment, &c., of plague; and yet here we have a commission, consisting of a number of the most able and highly qualified experts, examining, experimenting, criticising and discussing, and at the end of their labours they either fail to give a specific answer to the specific questions asked, or they are able to do so only in a fragmentary manner and under certain restrictions. The commissioners have not been able to trace when, whence and how plague came into Bombay; the commissioners are not able to state the manner in which plague was imported and how it spread in many localities in India; the commissioners are not able either to condemn or to recommend the use for therapeutic purposes of either Lustig's serum or Yersin's serum; and the commissioners express a not markedly decided, although on the whole a favourable, opinion about Haffkine's plague prophylactic. Although definite answers by the Commission to the four specific questions could not be given, many valuable opinions and facts concerning plague in India have been placed on record.

In the first place, the Commission distinguished the mild (or ambulating) form of true bubonic plague from the severe form, the former as "pestis minor," the latter as "pestis major." This is a timely and important statement, because recently some "plague experts" have tried to raise some febrile disease associated with glandular swelling, but which, according to their own showing, is not plague, that is to say, is not caused by the *Bacillus pestis*, to the position of "pestis minor," thereby creating and fostering misunderstanding.

Another important point is the confirmation by the Commission concerning the great importance of "locality" in the dissemination of plague (vol. v. p. 101). "The universal experience of plague in India proves . . . that houses into which the infection of plague has been imported, whether by man or by rats, are infective, this infectivity being so marked that many of the officers who have had most experience of the disease have come to the conclusion that the principal source of infection is . . . to be found in the houses into which the infection of plague has been introduced."

Unfortunately, the Commission did not find sufficient data to explain the nature of this factor. Equally unsatisfactory results attended the discussion as to the importance of rats in the dissemination of plague amongst human beings. But as regards the reality of the danger of clothes and personal effects of plague-infected persons in transmitting plague to new "localities," the Commission is very emphatic.

Not the least valuable part of the report consists in the indication of the nature of further work required for elucidating many of the points at present unsolved. Amongst these is the encouragement of further experimental work in the more accurate study of the blood of animals which furnish curative serum, and the importance of such work in obtaining a uniform strength and accurate standard of Haffkine's plague prophylactic.

E. KLEIN.

A. W. BENNETT.

ALFRED WILLIAM BENNETT, M.A., B.Sc., F.L.S., the well-known lecturer on botany at St. Thomas's Hospital, and for many years a prominent figure in botanical circles, died suddenly from heart disease on January 23. Born at Clapham in 1833, Mr. Bennett took the degree of B.A. (Lond.) in 1854, and afterwards spent ten years in business as a publisher. During this period he employed photography in the illustration of books, and was one of the first, if not the first, to do so. Shortly after taking his M.A. degree he had the misfortune to fall from a horse, an accident that somewhat seriously affected his health throughout his subsequent life. When the publication of NATURE was commenced, Mr. Bennett was appointed as the first sub-editor, and he occupied that postion for several years. He received the appointment of lecturer on botany at St. Thomas's Hospital nearly thirty years ago. Botanical students will remember Mr. Bennett as the translator of the third edition of Sachs's classical "Lehrbuch der Botanik" and of Thomé's Lehrbuch. His enthusiastic study of the flora of the Swiss Alps found expression in some important works for the use of students of Alpine botany. His translation of Dalla-Torre's "Tourist's Guide to the Flora of the Alps" was issued in 1886, and previously he edited Seboth's "Alpine Plants Painted from Nature," a work in four volumes. His useful "Flora of the Alps," in two octavo volumes, accompanied by 120 coloured plates, appeared in 1897. He devoted much attention to the Cryptogams, as witnessed by the excellent "Handbook of Cryptogamic Botany," a work executed in conjunction with Mr. George Murray and published in 1889. With regard to the systematic study of the Phanerogams, Mr. Bennett confined his labours chiefly to the Polygalaceæ, which he monographed for the "Flora of British India" and the "Flora Brasiliensis," dealing with the order also in some important papers contributed to the *Journal of Botany*. In the Royal Society's Catalogue of Scientific Papers he appears as the sole author of forty-six papers, many of which are based on his observations respecting the fertilisation of flowers. Elected a fellow of the Linnean Society in 1868, he served for some years on the council of that society, and was one of the vice-presidents for 1891–92. He was also a fellow of the Royal Microscopical Society, of which he was a vice-president in 1899–1900, and the editor of its *Journal* since 1897.

S. A. S.

NOTES.

AN influential committee has been formed with the object of establishing a memorial tower and meteorological station in honour of Dr. J. P. Joule, F.R.S., at Sale, Cheshire, where he lived from 1872 down to the time of his death in 1889. Sir W. H. Bailey has offered to the Sale District Council an automatic recording meteorological and public clock made from designs which are the result of his investigations and inquiries with regard to similar instruments in this country and abroad. The instrument will be unique in its details; will indicate the time as a public clock on large dials, produce automatic graphic records of the various changes of temperature and the fluctuations of atmospheric pressure, and also changes of the wind and the rainfall of the district. In addition to this gift, which will cost about 250*l.*, Mr. F. Armstrong has offered to the Council a set of instruments to equip a meteorological station, and the only condition attached to these gifts is that they shall be suitably housed. Designs for a building to be called "The Joule Memorial Tower," to contain the recording and other instruments, have been prepared, and the Council is willing to

permit the erection of such a building in the public park and recreation ground. In a room at the base of the building the meteorological instruments will be placed, and on one side of the exterior a tablet will be fixed on which there will be set a medallion portrait of Dr. Joule and a short record of his titles to fame. The cost of this tower will probably be 1000*l.*, which sum the District Council would have been willing to provide had its funds been applicable for such a purpose. As this course was not practicable, a committee has been formed at the instance of the District Council for the purpose of obtaining subscriptions to raise the amount required. Subscriptions should be sent to the hon. treasurer (Mr. A. H. Megson, The Priory, Sale), or the hon. secretary (Mr. J. W. Robson, Selbourne Lodge, Sale).

THE Royal Institution has received the following relics of Michael Faraday, bequeathed to it by the late Mr. Thomas J. F. Deacon, of Newcastle-on-Tyne:—Medals of silver and bronze (numbering twenty in all), and including the Fuller medal of 1828, two Copley medals of 1832 and 1838, two Newton medals of the Royal Society, 1833 and 1838, and the Rumford medal of 1846; and two foreign Orders, contained in a small mahogany box; a book of portraits and autographs, including original letters from the Prince of Wales and Prince Alfred (written in 1856), Louis Napoleon, Emperor of the French; Humphry Davy, Thomas Young, Humboldt, John Dalton, Whewell, Mary Somerville, and many others; a daguerreotype of a consultation of Faraday with Prof. Daniell; a drawing in colours of the laboratory of the Royal Institution, by a niece of Sir John Moore; and a manuscript book entitled "A Class Book for the Reception of Mental Exercises instituted July 1818," containing contributions by Faraday.

THE Council of the Society of Arts is prepared to award, under the terms of the Benjamin Shaw trust, a gold medal or a prize of 20*l.* "for any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb or health incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known or practically available means." Intending competitors should send in descriptions of their inventions not later than May 1, 1902, to the secretary of the Society of Arts, Adelphi, London, W.C.

THE Royal College of Physicians of London has appointed Dr. D. Ferrier, F.R.S., as Harveian orator for this year, Dr. Cullingworth as Bradshaw lecturer, and Dr. H. T. Bulstrode as Milroy lecturer.

THE manuscript of a French translation of Viete's works has been presented to the Paris Academy of Sciences by the family of the late M. F. Ritter, who devoted many years of his life in translating the Latin text and adding explanatory notes. The documents also include a history of the great geometrician's life and times.

ON Saturday, February 15, Lord Rayleigh will begin a course of six lectures at the Royal Institution on "Some Electrical Developments." The Friday evening discourse on Friday, February 7, will be delivered by Prof. E. Ray Lankester, his subject being "The New Mammal from Central Africa and other Giraffe-like Animals."

THE London County Council has appointed Prof. A. C. Haddon, F.R.S., advising curator in connection with the Horniman Museum at Forest Hill. It will be remembered that this museum was presented by its founder, Mr. E. J. Horniman, M.P., to the Council last year. It contains a fine collection of anthropological, art and natural history objects.

THE sixty-third anniversary meeting of the Royal Agricultural Society will be held on Thursday, May 22. The Society's annual exhibition of live stock, implements, poultry and produce will be held at Carlisle in the week commencing Monday, July 7. An appeal has been issued by the Society for funds for the purchase and preparation of the site in the metropolis which has been selected for the future permanent showyard of the Society.

PROF. E. MILLOSEVICH has succeeded Prof. P. Tacchini as director of the Astronomical Observatory of the Roman College and of the astronomical museum connected with it. Prof. Tacchini has resigned his office of administrator in the Reale Accademia dei Lincei, and Prof. Volterra has been appointed as his successor. Prof. P. Villari having been unable to accept the office as president, an election to the presidential chair will be made early in June.

THE executive committee of the Jenner Society has resolved that, in view of the provisional character of the Vaccination Act of 1898, and as a preliminary to the further legislation which must be adopted next year in fulfilment of the promise made by the Government in regard to revaccination and of the termination of the experimental period for which the Act was passed, a comprehensive and careful inquiry should be made into the working of the administrative machinery by which vaccination is promoted as well as of the results of the Act itself.

AT the annual general meeting of the Royal Scottish Arboricultural Society, held in Edinburgh on Friday last, Lord Mansfield said he was authorised to state that it was Mr. Hanbury's intention to appoint a departmental committee to inquire into and report upon the present position and future prospects of forestry and the planting and management of woodlands in the United Kingdom, and to consider whether any further measures might be taken with advantage, either by the provision of further educational facilities or otherwise, for their promotion and encouragement. Mr. Munro-Ferguson, M.P., has been invited and has consented to act as chairman of the committee.

MR. S. HARBERT HAMILTON has started on a scientific exploring and collecting trip of several months' duration in the vicinity of Santiago, Cuba. Collections will be made in all branches of natural history, the bulk of which will go to the New York Botanical Gardens, the American Museum of Natural History and the Academy of Natural Sciences of Philadelphia. Specialists or institutions desiring material in any branches direct from the locality are invited to correspond with Mr. Hamilton at Santiago, Cuba.

THE meeting of the British Ornithologists' Club on March 19 is to be specially devoted to an exhibition of photographic slides, illustrating bird-life of all kinds, taken by members of the Club and their friends in various parts of the world. It is expected that a large number of very interesting light-pictures will be shown on this occasion.

FROM the *American Field* we learn that a young female specimen of that rare Arctic mammal, the musk-ox (*Ovibos moschatus*), reached Chicago alive at the beginning of January last. It is said to have been captured by hunters employed for the purpose by Captain H. H. Bodfish, of the steam-whaler *Beluga* (of San Francisco), near Cape Bathurst in the Arctic Ocean. A figure is given of this animal, which is stated to be the only living musk-ox ever brought alive to the United States. The only specimen of the musk-ox in England is that belonging to the Duke of Bedford at Woburn. There are, however, said to be also examples of this animal in the Zoological Gardens of Copenhagen and Berlin.

WE are glad to be able to record the formation of an Acetylene Association, which is similar in character to the associations which have existed for some time in several countries abroad. The object of the Association, as stated in the articles thereof, is "To promote the advancement of acetylene gas engineering and manufacture, and to facilitate the interchange of information amongst the members of the Association." An attempt was made in 1898 to found such an association, largely on the initiation of Sir David Salomons, but the trade did not then show sufficient general interest in the matter to make this possible. In reviewing this attempt a note of bitterness is sounded as to the opposition which every new industry started in this country has to encounter. Perhaps we may hope that the functions of the National Physical Laboratory will be wide enough in scope to make such repinings unnecessary, by giving new industries a helping hand in the future. The chairman of the Association is Mr. F. G. Worth, manager of the Acetylene Illuminating Company, who, as one of the prime movers in the formation of the Association, has devoted much time and care to bringing matters to a successful issue. The members of the council as at present constituted are nearly all members of well-known firms interested in acetylene, but several vacancies have yet to be filled up at the first annual general meeting, to be held on February 27. Subsequent to this, meetings will be arranged at which papers will be read and discussed. The official organ of the Association is, for the present, the *Journal of Acetylene Gas Lighting*, and the present secretary is Mr. Lacey Downes, of 11, Ironmonger Lane, Cheapside.

DURING the past week this country, in common with the greater part of western Europe, has been visited with inclement weather and very keen north-east winds. In Scotland the temperature in the screen has fallen 20° and more below the freezing point, the minimum reading during Friday night being 7° at Nairn. In the south the thermometer has not been much below the freezing point, but the north-east wind has been stronger than in the north, and this has greatly added to the sensation of cold. The barometer has risen above 31 inches in the north of Scotland, the reading at Aberdeen being 31·11 inches at 10 p.m. on Friday, which is as high as the very exceptional reading in our islands in January, 1896. Barometrical gradients have been very steep over the south of England and in France and Germany, which have given rise to fierce north-easterly gales in the Channel and over the southern portion of the North Sea. The gales have been unusually prolonged, continuing without interruption for about three days.

IN one of the important articles contained in vol. xxiii. of *Aus dem Archiv der Deutschen Seewarte*, Dr. Grossmann discusses the results of the maximum and minimum temperatures at Hamburg during the last quarter of a century (1876-1900). During this period the highest readings were 89°·6 in July 1883, and 89°·1 in May 1892. The lowest were −3°·6 in December 1876, and −1°·1 in January 1893. Temperatures of 86°·0 and upwards were recorded seventeen times between May and August, and 3°·0 and below also seventeen times between December and February. If we denote as summer days those on which the highest temperature reached or exceeded 77°, and as wintry days those on which the temperature remained below the freezing point, we find that the latter were twice as frequent as the former. The distribution shows that the so-called wintry days occurred as late as March and as early as November, and that the summer days occurred as early as May and as late as September. April and October were the most temperate months; the highest reading did not exceed 77°, and the lowest did not fall below the freezing point.

AN interesting paper by Herr Hofrath J. Hann appears in a January number (No. 1, 1902) of the *Transactions* of the section of mathematics and natural sciences of the Vienna Academy of Sciences, entitled "The Variations of Rainfall during long Periods of Time." Herr Hann discusses the monthly and yearly means of the values of the rainfall for the stations Padua (1725-1900), Klagenfurt (1813-1900) and Mailand (1764-1900), and finds that they all conform to a period of definite length. In the investigation he first of all obtains the extreme yearly sums of the rainfall expressed in per cent. of the total mean, and finds the following values for the past century (1801-1900):—

Driest year....	Padua 58	Klagenfurt 42	Mailand 62	per cent.
Wettest ,, ...	,, 152	,, 151	,, 152	,,

Using the earlier observations of Padua so far back as 1725, the extremes for this station became 56 per cent. and 181 per cent. Taking the frequency of similar yearly totals during the last hundred years, he groups the wet and dry years as shown in the following summary:—

Character	Very dry	Dry	About normal	Wet	Very wet	Extra-ordinarily wet
Per cent...	51-70	71-90	91-110	111-130	131-150	over 150
Number...	8	26	37	22	6	1

These figures show that the dry years predominate, 34 per cent. being dry and 29 per cent. wet, but the wet years exceed to a greater extent the mean yearly value of rainfall than the dry years. Herr Hann then determines the mean epochs of these wet and dry periods and finds that they satisfy a thirty-five-year period, with their maxima (wet) and minima (dry) in the following years:—

Wet..........	1738	1773	1808	1843	1878	(1913)
Dry..........	1753	1788	1823	1859	1893	(1928).

This period of thirty-five years and the above epochs are in complete harmony with the secular variation of rainfall indicated by Brückner in his "Klima-schwankungen," and agree with the long-period variation of sunspots recently shown to exist by Dr. Lockyer.

THE Report of the museum committee of the Bristol Museum for 1901 shows that many desirable improvements were effected by the curator, Mr. H. Bolton. The condition of the specimens has been greatly improved; in particular, the cases of birds have been thoroughly worked over, many of the birds being remounted. As the only trained official in the Museum is Mr. Bolton himself, though the Museum is a large one and belongs to the city, the fact that so much was done last year is a testimony to the zeal of the curator. Perhaps the most important work of the kind is that which has been effected upon the numerous and valuable Liassic fossil reptiles, which were in a very unsatisfactory condition. By arrangement with the authorities of the British Museum of Natural History, the worst of the specimens have been thoroughly repaired by one of their expert staff, and in this way they have been saved from further injury. Thanks to the committee of the Egypt Exploration Fund, the Museum possesses one of the most complete collections of Egyptian antiquities to be found in the provinces, and it has the advantage of being compact and consecutive in historical continuity rather than large and disconnected. The Museum is evidently appreciated, for the number of visitors in 1901 was 116,246, which is nearly twice as many as in 1898, when the present curator commenced his duties. The long and valuable list of donations also shows that interest is taken in the work of the Museum, but it is difficult to see how these gifts can be properly taken in hand, registered, classified and exhibited to the best advantage by the present very inadequate scientific staff. The latest donation is from Lady Smyth, who has presented to the Museum a large part of the

natural history collections of the late Sir Greville Smyth. Among the specimens are a fine egg of the Great Auk, an egg of the *Aepyornis maximus*, a collection of British and foreign birds' eggs and nests, a large collection of birds' skins, comprising a skin of the Apteryx, a collection of the Lepidoptera of India, Ceylon, South America and southern Europe, and also a very complete collection of British species, a collection of exotic Coleoptera, and a choice series of shells. The whole of these valuable natural history specimens are contained in a costly range of cabinets. Lady Smyth has also promised to present two specimen heads of the red deer bred in Ashton Park.

THE "Acker" fusion process for the electrolytic production of caustic alkali and chlorine is reported to be working successfully at Niagara Falls. The process depends upon the decomposition of molten salt with a carbon anode, and a kathode of molten lead. A lead-sodium alloy is formed at the kathode. The circulation and renewal of the molten kathode material is effected by means of high-pressure-steam and an injector. The lead-sodium alloy is carried into a separate vessel, where the steam decomposes the alloy with formation of sodium hydrate, hydrogen and lead. By careful regulation of the steam supply, the caustic alkali can be obtained as fused anhydrous NaOH, and the necessity for evaporation of the surplus water at a later stage is avoided. The hydrogen gas is collected and burnt, the heat being utilised for the preliminary heating of the rock salt used to feed the cell; while the molten lead flows back into the cell and functions again as kathode. The mechanical difficulties that have had to be surmounted in the transfer of this process from the laboratory to the works have been great, but, according to the *Electrician* of January 17, 3000 h.p. is now being utilised by this most interesting process at Niagara Falls, and anhydrous caustic soda is being produced, without any after boiling-down or evaporation. This latter is one of the chief features of the Acker process, and if the saving in fuel which results is not balanced by very heavy charges for cell maintenance and repairs, the process would appear to have a highly successful future before it.

THE *Bulletin international* of the Cracow Academy for November, 1901, contains an account, by M. L. Marchlewski, of the researches of the late Prof. Marcellus Nencki. Nencki was born in 1847 at Sieradz, Poland, and studied at Cracow, Jena and Berlin. He held office as assistant lecturer in pathological anatomy at Bern, and in 1878 was appointed professor of physiological chemistry. From 1891 till his death he was head of the chemical department of the Institute for Practical Medicine at St. Petersburg. He made many important advances in the study of physiological chemistry.

THE *Rendiconto* of the Naples Academy contains a short abstract of a paper by G. de Lorenzo, to be published in the *Atti* of the Academy, dealing with the superficial origin of volcanoes. Signor de Lorenzo seeks to prove, from a study of the volcanoes of southern Italy, that eruptive phenomena in general, and volcanic phenomena in particular, are intimately connected with mountain formation, and like the latter represent purely superficial effects on the earth, a view which is inconsistent with the hypothesis that they are due to an incandescent central fluid mass within. Signor de Lorenzo has illustrated his theory by pictures of Monte Nuovo, a hill of which the only illustration, even in recent treatises, has been that of Hamilton, dating from last century.

THE *Journal* of the Society of Arts contains a paper by Mr. Frank Gray on elliptographs. The various mechanical apparatus for drawing an ellipse are considered by Mr. Gray to depend on four methods, namely, the focal method, the trammel method, the mechanical method and the projective method. After reading the paper we are inclined to think that while the instruments described by Mr. Gray are highly ingenious, there is still room for someone to invent a really *simple* and portable instrument for drawing circles in perspective, an operation that is of constant occurrence in geometrical drawing. Many of the instruments described appear to be best suited to drawing large ellipses, whereas small ellipses are often required for diagrammatic illustrations. Moreover, a further desideratum is to be able to adjust easily an instrument to draw an ellipse of given dimensions, in particular one where two conjugate diameters, instead of the principal axes, are given. Among the instruments considered by Mr. Gray was Nasmyth's instrument now in the possession of the Board of Education. It is remarkable that so late as 1894 two Germans obtained a patent in Great Britain for a "trammel, pure and simple."

AN important paper on the electromagnetic properties of convection currents is published by Prof. A. Righi in the *Nuovo Cimento* (5, ii). It deals with the four fundamental principles according to which it is believed that (1) a moving charge generates a magnetic field, (2) changes in a magnetic field produce an electrostatic field, (3) a moving pole generates an electrostatic field, (4) changes in an electrostatic field produce a magnetic field. Experiments of Crémieu have thrown some doubt on the production of a magnetic field by convection of electrostatic charges, and even the existence of unclosed currents has been suggested. Prof. Righi gives a critical examination of Crémieu's experiments, as also of those of Rowland, Lodge, Wilson, Pender and others, and describes experiments in verification of the second of the four phenomena. The general conclusion is that Crémieu's experiments need not shake our faith in modern electrical theory, although it still appears desirable, if not necessary, that new and accurate researches should be undertaken for the purpose of confirming the above four phenomena individually as well as other phenomena depending on the same laws.

WE have received from the publisher (Mr. L. U. Gill) a copy of the seventh issue of that useful little work, "The Naturalists' Directory." The new volume appears to be much better than its predecessors.

THE *Proceedings* of the Indiana Academy of Sciences for 1900 contains a list of the papers read at the sixteenth annual meeting, many of these being printed only in brief abstract. The president's address is illustrated with some excellent reproductions of photographs of microscopic objects.

IN the Report for the year 1901, the Northumberland Sea Fisheries Committee gives a most satisfactory account of the food-fishes of the district, based on the experimental trawling excursions carried on during the past ten years. The results for the whole four stations where the experiments have been conducted are as follows:—"Turbot have remained steady; brill seem to be improving in numbers; soles are getting less numerous every year, practically speaking; plaice have slightly improved, and dabs have greatly improved in numbers; flounders also presented a slight increase." A total increase of about 20 per cent. in the number of food-fishes frequenting the bays is estimated to have taken place during the last five years, and the Committee therefore feels justified in saying that the locality is slowly recovering from the effects of the excessive in-shore trawling carried on just previous to the commencement of the experiments.

THE *Scientific American* for January 18 issues a supplement (No. 1359) devoted to a comparison of the Panama and Nicaragua canal routes. The supplement contains an exhaustive

article on each canal and a digest of the report of the Canal Commission; it is illustrated by about forty views and diagrams. In the ordinary number is a short summary of the matter to be found in the supplement, and a full-page illustration showing the two canals in plan.

The *National Geographic Magazine* publishes, as a supplement to its January number, the official map of the Philippines prepared by the United States Signal Officer under the direction of General Greely. The map is in two sheets, on a scale of 1 : 900,000, and shows telegraph lines and cables, telephone lines, open ports, lighthouses and post offices. The spelling of names is that adopted by the U.S. Board on Geographic Names. A remarkable feature is the large amount of country, in the island of Mindoro especially, which remains blank on the map, awaiting exploration.

Dr. Martin Knudsen contributes a paper on the oceanography of the straits connecting the Baltic and the North Sea to the January number of *La Geographie*, in which he gives a short account of the work of the Danish Commission during the past ten years, and brings it into relation with the researches of Pettersson and Ekman. The seasonal variations of the inflowing and outflowing streams are fully described; a section is devoted to the discussion of the distribution of temperature in the Kattegat and the western Baltic, and another to the relative volumes of the Baltic current and the inflowing current of salter water, as deduced from the salinity observations. With regard to the Baltic current, the remarkable result has been arrived at that its volume is four to six times greater than can be accounted for by the supply of fresh water by rainfall in the Baltic basin alone, and that this cause is largely assisted by the winds and by the variations of atmospheric pressure on the surface of the sea itself.

A catalogue of the types and figured fossils in the geological department of the American Museum of Natural History, New York, has been published as the eleventh volume of the *Bulletin* of the Museum. It is needless to say that such catalogues are of great service to palæontologists. The Museum contains the James Hall collection, which includes a large number of type and figured Palæozoic fossils; it also contains other interesting and important collections from strata of various ages in North America, including the fruits and seeds from the Eocene beds of Brandon, Vermont, described by Lesquereux, Pliocene and post-Pliocene fossils from South Carolina, &c. There are also Cretaceous fossils from Syria, Jamaica, &c. The term "type" is employed to embrace not only the specimens actually used by an author in the original description of a species, but those specimens which have been used by the same author in the further elucidation of the species in subsequent publications. This valuable record, for which we are indebted to Mr. R. P. Whitfield, the curator, and his associate, Mr. E. O. Hovey, enumerates 8345 type and figured specimens, representing 2721 species and 190 varieties.

Among the forthcoming publications of the Clarendon Press is an authorised translation of Schimper's "Geography of Plants," by Profs. Percy Groom and W. R. Fisher.

The third volume of Lord Rayleigh's collected papers, containing papers published from 1887 to 1892, has been published by the Cambridge University Press. The next volume will bring the collection down to nearly the present time, and will, it is hoped, be ready in about a year. The complete work will then be reviewed in these columns.

Messrs. F. Vieweg and Son, Brunswick, announce that the preparation of a biography of the late Prof. Helmholtz has been undertaken by Prof. Leo Königsberger, and will be published by them. The work will contain the letters which passed between Helmholtz and his father, and correspondence with personal and scientific friends. Many men of science will look forward with pleasure to the publication of the biography of one who contributed so much to the progress of natural knowledge.

Mr. H. K. Lewis, of Gower Street, W.C., is extending his circulating library of medical and scientific books. New books and new editions are added to the library immediately on publication, so that it is possible for students with limited incomes to keep themselves in close touch with all important additions to scientific literature. The library provides a useful means for obtaining standard works for study, or for examination with a view to purchase. The lists of scientific books and periodicals circulated by Mr. Lewis are worth attention.

In the Siebenbürgen salt district (Transylvania) are some warm salt lakes which have recently been examined by A. V. Kalecsinsky, chemist to the Hungarian Geological Survey. They are remarkable for having a layer of warm or even hot salt water between two colder bodies of water, the surface being fresh water while the rest is highly saline. In the Medoc See, for example, when the surface was in summer at a temperature of 21° C., at a depth of 1·3 metres the temperature was 56° C. and the specific gravity 1·17, thence declining gradually to the bottom to 19° C. with a specific gravity of 1·19, corresponding to 25 per cent. of salt in solution. The warm layer in summer has been found to reach 70° to 71° C., but during winter months it cools until the minimum in May is only 26° C. The author concludes that the lakes are not fed by hot springs nor warmed by chemical agency, but derive their heat from the sun. As the specific heat of brine is below that of water, the saline water is more readily warmed, and the fresh surface water prevents any rapid loss of heat by radiation. Some future useful application may, he thinks, be made of these natural heat-accumulators.

The additions to the Zoological Society's Gardens during the past week include two Vulpine Phalangers (*Trichosurus vulpecula*), two Laughing Kingfishers (*Dacelo gigantea*) from Australia, a Weka Rail (*Ocydromus australis*) from New Zealand, presented by H.R.H. the Prince of Wales, K.G.; a Malayan Paradoxure (*Paradoxurus hemaphroditus*) from Burmah, presented by Capt. Burnett; a Red-bellied Spider Monkey (*Ateles rufiventris*) from Colombia, a Long-haired Spider Monkey (*Ateles vellerosus*) from Central America, a Bungoma River Turtle (*Emyda granosa*), seven Roofed Terrapins (*Kachuga tectum*), five Hamilton's Terrapins (*Damonia hamiltoni*) from India, two Bicheno's Finches (*Estrelda bichenovii*) from Australia, deposited; a Sykes's Monkey (*Cercopithecus albigularis*) from East Africa, purchased; three Red River Hogs (*Potamochaerus penicillatus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

Early Observations of Algol Stars.—In the *Harvard College Observatory Circular*, No. 64, Prof. E. C. Pickering furnishes particulars of additional observations of recently discovered variables, which have been obtained from examination of the photographs taken with the 8-inch Draper telescope.

78 (1901) Cygni.—R.A. = 20h. 18m. 4s.·0; Decl. = +42° 46′·4 (1855).

This star was announced as variable by Mr. Williams. On referring to the Harvard collection the star has been found on 177 plates, the first being on 1885 September 19 ten of the photographs showing the star to be fainter than the normal brightness. Determinations with the 12-inch meridian photometer give the maximum magnitude as 10·47, and taking this value, a light curve has been determined from observations with the 15-inch equatorial. The magnitude appears to decrease to about 13·05 at minimum. With an adopted period of 3d. 10h. 49m. 12s. a table of residuals is formed from the old and new measures, and more accurate results will probably

be obtained when the photographic light curve is better known, and also by correcting for aberration.

93 (1901) Sagittæ.—R.A. = 19h. 14m. 26s.; Decl. = $+19°$ $25'·4$ (1900).

The variability of this star was announced by Dr. Schwab, and subsequent inspection of the Harvard plates showed that there were 155 records of nearly normal brightness, the magnitude at this stage being 6·50, and 13 where the star was near minimum. A photograph obtained on 1895 August 22 shows a sudden change during the exposure from 9th to 8th magnitude. The range in light appears to be greater than that of any other Algol star. The suggested period of seventeen days does not appear to satisfy the observations, and observers in other situations are asked to forward any determinations as soon as possible.

UNITED STATES NAVAL OBSERVATORY REPORT.—The report of work accomplished at this observatory during the year ending June 30, 1901, has recently been distributed, and is here summarised.

26-inch Equatorial.—This instrument has been in charge of Prof. See, who has been engaged in determinations of the diameters of the planets and satellites of the solar system, observations of Eros for parallax, double star observations, &c. These, so far as reduced, have been published from time to time in the *Astronomische Nachrichten.*

12-inch Equatorial.—During the greater part of the year this has been dismounted for repairs. Since its readjustment it has been used for the observation of zone stars, double stars, &c., and also for the entertainment of visitors to the observatory, 765 admission cards having been issued during the year.

9-inch Transit Circle.—The regular sun, moon and planet work has been continued, and in addition a revision of the Astronomische Gesellschaft zones and the zone of zodiacal stars undertaken for the Paris Astronomical Conference of 1896. The instrument is in need of thorough repair, as an examination of the pivots reveals considerable inequalities, and the present method of oblique illumination is to be replaced by an axial arrangement.

6-inch Transit Circle.—Observations have been continued on comparison stars for planets, special stars for Eros reductions, and determinations of personal equation. A serious difficulty, however, has been the persistence of the large diurnal change of azimuth with temperature. Numerous experiments have been made, but the error is only partially remedied.

Clock Vault.—A considerable amount of time has been spent in an attempt to bring the timekeepers under more constant conditions. A vault eight feet square and seven feet high has been made in the basement of the observer's room near the 6-inch transit circle. In this a 9-inch brick wall encloses a wooden hut, with an intervening air space of one foot containing hot water pipes. The roof is covered over with boards enclosing a 6-inch layer of asbestos wool. The room is entered by triple doors, and it is hoped that by these precautions constant temperature conditions will be attained. The whole is on the summit of a hill to avoid drainage difficulties.

Prime Vertical Transit and 5-inch Altazimuth.—These instruments have been used in conjunction for the determination of latitude variation, the two distinct types of observation constituting a valuable check on the accuracy of results obtained.

40-foot Photoheliograph.—During the year photographs of the sun were obtained on 116 days. Of these, sunspots were recorded on 24 days. The photographs show many faculæ and fine detail in the granulation of the solar surface.

Nautical Almanac.—This is now under the direction of Prof. W. S. Harshman. Special effort is to be made to ensure the publication three years in advance. Investigations are being made to provide tables for Jupiter's satellites and the inner satellite of Uranus, and a new catalogue of zodiacal stars for computing occultations will be used in the preparation of the volume for 1905.

For a considerable time an important section of the staff was absent on the eclipse expedition to Sumatra. Although most of the parties were unfortunate in having bad weather, the observers at Fort de Kock obtained excellent photographs of the phenomenon.

Meteorological observations have been continued as in former years, but all the magnetic determinations have been discontinued owing to the interference of currents from the various electric systems in the neighbourhood.

THE DISCOVERY OF THE FUTURE.[1]

IT will lead into my subject most conveniently to contrast and separate two divergent types of mind, types which are to be distinguished chiefly by their attitude towards time and more particularly by the relative importance they attach and the relative amount of thought they give to the future of things.

The first of these two types of mind, and it is, I think, the predominant type, the type of the majority of living people, is that which seems scarcely to think of the future at all, which regards it as a sort of black non-existence upon which the advancing present will presently write events. The second type, which is, I think, a more modern and much less abundant type of mind, thinks constantly and by preference of things to come, and of present things mainly in relation to the results that must arise from them. The former type of mind, when one gets it in its purity, is retrospective in habit, and it interprets the things of the present, and gives value to this and denies it to that, entirely with relation to the past. The latter type of mind is constructive in habit, it interprets the things of the present and gives value to this or that, entirely in relation to things designed or foreseen. While from that former point of view our life is simply to reap the consequences of the past, from this our life is to prepare the future. The former type one might speak of as the legal or submissive type of mind, because the business, the practice and the training of a lawyer dispose him towards it; he of all men must most constantly refer to the law made, the right established, the precedent set, and most consistently ignore or condemn the thing that is only seeking to establish itself. The latter type of mind I might for contrast call the legislative, creative, organising or masterful type, because it is perpetually attacking and altering the established order of things, perpetually falling away from respect for what the past has given us. It sees the world as one great workshop, and the present is no more than material for the future, for the thing that is yet destined to be. It is in the active mood of thought while the former is in the passive; it is the mind of youth, it is the mind more manifest among the western nations while the former is the mind of age, the mind of the oriental.

Things have been, says the legal mind, and so we are here. And the creative mind says, we are here, because things have yet to be.

Now I do not wish to suggest that the great mass of people belong to either of these two types. Indeed, I speak of them as two distinct and distinguishable types mainly for convenience and in order to accentuate their distinction. There are probably very few people who brood constantly upon the past without any thought of the future at all, and there are probably scarcely any who live and think consistently in relation to the future. The great mass of people occupy an intermediate position between these extremes, they pass daily and hourly from the passive mood to the active, they see this thing in relation to its associations and that thing in relation to its consequences, and they do not even suspect that they are using two distinct methods in their minds.

But for all that they are distinct methods, the method of reference to the past and the method of reference to the future, and their mingling in many of our minds no more abolishes their difference than the existence of piebald horses proves that white is black.

I believe that it is not sufficiently recognised just how different in their consequences these two methods are, and just where their difference and where the failure to appreciate their difference takes one. This present time is a period of quite extraordinary uncertainty and indecision upon endless questions—moral questions, æsthetic questions, religious and political questions—upon which we should all of us be happier to feel assured and settled, and a very large amount of this floating uncertainty about these important matters is due to the fact that with most of us these two insufficiently distinguished ways of looking at things are not only present together, but in actual conflict in our minds, in unsuspected conflict; we pass from one to the other heedlessly without any clear recognition of the fundamental difference in conclusions that exists between the two, and we do this with disastrous results to our confidence and to our consistency in dealing with all sorts of things.

But before pointing out how divergent these two types or habits of mind really are, it is necessary to meet a possible objection to what has been said. I may put that objection in this

[1] A discourse delivered at the Royal Institution on Friday, January 24, by Mr. H. G. Wells.

form—Is not this distinction between a type of mind that thinks of the past and of a type of mind that thinks of the future a sort of hair-splitting almost like distinguishing between people who have left hands and people who have right? Everybody believes that the present is entirely determined by the past, you say; but, then, everybody believes *also* that the present determines the future. Are we simply separating and contrasting two sides of everybody's opinion? To which one replies that we are not discussing what we know and believe about the relations of past, present and future, or of the relation of cause and effect to each other in time. We all know the present depends for its causes on the past and that the future depends for its causes upon the present. But this discussion concerns *the way in which we approach things* upon this common ground of knowledge and belief. We may all know there is an east and a west, but if some of us always approach and look at things from the west, if some of us always approach and look at things from the east, and if others again wander about with a pretty disregard of direction, looking at things as chance determines, some of us will get to a westward conclusion of this journey, and some of us will get to an eastward conclusion, and some of us will get to no definite conclusion at all about all sorts of important matters. And yet those who are travelling east, and those who are travelling west, and those who are wandering haphazard, may be all upon the same ground of belief and statement and amidst the same assembly of proven facts. Precisely the same thing will happen if you always approach things from the point of view of their causes, or if you approach them always with a view to their probable effects. And in several very important groups of human affairs it is possible to show quite clearly just how widely apart the two methods, pursued each in its purity, take those who follow them.

I suppose that three hundred years ago all people who thought at all about moral questions, about questions of right and wrong, deduced their rules of conduct absolutely and unreservedly from the past, from some dogmatic injunction, some finally settled decree. The great mass of people do so to-day. It is written, they say. Thou shalt not steal, for example—that is the sole, complete and sufficient reason why you should not steal, and even to-day there is a strong aversion to admit that there is any relation between the actual consequences of acts and the imperatives of right and wrong. Our lives are to reap the fruits of determinate things, and it is still a fundamental presumption of the established morality that one must do right though the heavens fall. But there are people coming into this world who would refuse to call it right if it brought the heavens about our heads, however authoritative its sources and sanctions, and this new disposition is, I believe, a growing one. I suppose in all ages people in a timid, hesitating, guilty way have tempered the austerity of a dogmatic moral code by small infractions to secure obviously kindly ends, but it was, I am told, the Jesuits who first deliberately sought to qualify the moral interpretation of acts by a consideration of their results. To-day there are few people who have not more or less clearly discovered the future as a more or less important factor in moral considerations. To-day there is a certain small proportion of people who frankly regard morality as a means to an end, as an overriding of immediate and personal considerations out of regard to something to be attained in the future, and who break away altogether from the idea of a code dogmatically established for ever. Most of us are not so definite as that, but most of us are deeply tinged with the spirit of compromise between the past and the future; we profess an unbounded allegiance to the prescriptions of the past, and we practise a general observance of its injunctions, but we qualify to a vague, variable extent with considerations of expediency. We hold, for example, that we must respect our promises. But suppose we find unexpectedly that for one of us to keep a promise, which has been sealed and sworn in the most sacred fashion, must lead to the great suffering of some other human being, must lead, in fact, to practical evil? Would a man do right or wrong if he broke such a promise? The practical decision most modern people would make would be to break the promise. Most would say that they did evil to avoid a greater evil. But suppose it was not such *very* great suffering we were going to inflict, but only some suffering? And suppose it was a rather important promise? With most of us it would then come to be a matter of weighing the promise, the thing of the past, against this unexpected bad consequence, the thing of the future. And the smaller the overplus of evil consequences, the more most of us would vacillate. But neither of the two types of mind we are contrasting would vacillate at all. The legal type of mind would obey the past unhesitatingly, the creative would unhesitatingly sacrifice it to the future. The legal mind would say, "they who break the law at any point, break it altogether," while the creative mind would say, "let the dead past bury its dead." It is convenient to take my illustration from the sphere of promises, but it is in the realm of sexual morality that the two methods are most acutely in conflict.

And I would like to suggest that until you have definitely determined either to obey the real or imaginary imperatives of the past, or to set yourself towards the demands of some ideal of the future, until you have made up your mind to adhere to one or other of these two types of mental action in these matters, you are not even within hope of a sustained consistency in the thought that underlies your acts, that in every issue of principle that comes upon you, you will be entirely at the mercy of the intellectual mood that happens to be ascendant at that particular moment in your mind.

In the sphere of public affairs also, these two ways of looking at things work out into equally divergent and incompatible consequences. The legal mind insists upon treaties, constitutions, legitimacies and charters; the legislative incessantly assails these. Whenever some period of stress sets in, some great conflict between institutions and the forces in things, there comes a sorting between these two types of mind. The legal mind becomes glorified and transfigured in the form of hopeless loyalty, the creative mind inspires revolutions and reconstructions. And particularly is this difference of attitude accentuated in the disputes that arise out of wars. In most modern wars there is no doubt quite traceable on one side or the other a distinct creative idea, a distinct regard for some future consequence. But the main dispute even in most modern wars and the sole dispute in most mediæval wars will be found to be a reference, not to the future, but to the past; to turn upon a question of fact and right. The wars of Plantagenet and Lancastrian England with France, for example, were based entirely upon a dummy claim, supported by obscure legal arguments, upon the crown of France. And the arguments that centre about the present war in South Africa ignore any ideal of a great united South African State almost entirely, and quibble this way and that about who began the fighting and what was or was not written in some obscure revision of a treaty a score of years ago. Yet beneath the legal issues, the broad creative idea has been very apparent in the public mind during this war. It will be found more or less definitely formulated beneath almost all the great wars of the past century, and a comparison of the wars of the nineteenth century with the wars of the middle ages will show, I think, that in this field also there has been a discovery of the future, an increasing disposition to shift the reference and values from things accomplished to things to come.

Yet though foresight creeps into our politics and a reference to consequence into our morality, it is still the past that dominates our lives. But why? Why are we so bound to it? It is into the future we go, to-morrow is the eventful thing for us. There lies all that remains to be felt by us and our children and all those that are dear to us. Yet we marshal and order men into classes entirely with regard to the past, we draw shame and honour out of the past; against the rights of property, the vested interests, the agreements and establishments of the past, the future has no rights. Literature is for the most part history or history at one remove, and what is culture but a mould of interpretation into which new things are thrust, a collection of standards, a sort of bed of King Og, to which all new expressions must be lopped or stretched? Our conveniences, like our thoughts, are all retrospective. We travel on roads so narrow that they suffocate our traffic; we live in uncomfortable, inconvenient, life-wasting houses out of a love of familiar shapes and familiar customs and a dread of strangeness, all our public affairs are cramped by local boundaries impossibly restricted and small. Our clothing, our habits of speech, our spelling, our weights and measures, our coinage, our religious and political theories, all witness to the binding power of the past upon our minds. Yet—we do not serve the past as the Chinese have done. There are degrees. We do not worship our ancestors or prescribe a rigid local costume; we venture to enlarge our stock of knowledge, and we qualify the classics with occasional adventures into original thought. Compared with the Chinese we are distinctly aware

of the future. But compared with what we might be, the past is all our world.

The reason why the retrospective habit, the legal habit, is so dominant and always has been so predominant, is of course a perfectly obvious one. We follow the fundamental human principle and take what we can get. All people believe the past is certain, defined and knowable, and only a few people believe that it is possible to know anything about the future. Man has acquired the habit of going to the past because it was the line of least resistance for his mind. While a certain variable portion of the past is serviceable matter for knowledge in the case of everyone, the future is, to a mind without an imagination trained in scientific habits of thought, non-existent. All our minds are made of memories. In our memories each of us has something that without any special training whatever will go back into the past and grip firmly and convincingly all sorts of workable facts, sometimes more convincingly than firmly. But the imagination, unless it is strengthened by a very sound training in the laws of causation, wanders like a lost child in the blackness of things to come and returns—empty.

Many people believe, therefore, that there can be no sort of certainty about the future. You can know no more about the future, I was recently assured by a friend, than you can know which way a kitten will jump next. And to all who hold that view, who regard the future as a perpetual source of convulsive surprises, as an impenetrable, incurable, perpetual blackness, it is right and reasonable to derive such values as it is necessary to attach to things from the events that have certainly happened with regard to them. It is our ignorance of the future and our persuasion that that ignorance is absolutely incurable that alone gives the past its enormous predominance in our thoughts. But through the ages, the long unbroken succession of fortune tellers—and they flourish still—witnesses to the perpetually smouldering feeling that after all there *may* be a better sort of knowledge—a more serviceable sort of knowledge than that we now possess.

On the whole there is something sympathetic for the dupe of the fortune teller in the spirit of modern science; it is one of the persuasions that come into one's mind, as one assimilates the broad conceptions of science, that the adequacy of causation is universal; that in absolute fact, if not in that little bubble of relative fact, which constitutes the individual life, in absolute fact the future is just as fixed and determinate, just as settled and inevitable, just as possible a matter of knowledge as the past. Our personal memory gives us an impression of the superior reality and trustworthiness of things in the past, as of things that have finally committed themselves and said their say, but the more clearly we master the leading conceptions of science the better we understand that this impression is one of the results of the peculiar conditions of our lives and not an absolute truth. The man of science comes to believe at last that the events of the year A.D. 4000 are as fixed, settled and unchangeable as the events of the year 1600. Only about the latter he has some material for belief and about the former practically none.

And the question arises how far this absolute ignorance of the future is a fixed and necessary condition of human life, and how far some application of intellectual methods may not attenuate even if it does not absolutely set aside the veil between ourselves and things to come. And I am venturing to suggest to you that, along certain lines and with certain qualifications and limitations, a working knowledge of things in the future is a possible and practicable thing.

And in order to support this suggestion I would call your attention to certain facts about our knowledge of the past, and more particularly I would insist upon this, that about the past our range of absolute certainty is very limited indeed. About the past I would suggest we are inclined to overestimate our certainty, just as I think we are inclined to underestimate the certainties of the future. And such a knowledge of the past as we have is not all of the same sort, or derived from the same sources.

Let us consider just what an educated man of to-day knows of the past. First of all he has the reallest of all knowledge, the knowledge of his own personal experiences, his memory. Uneducated people believe their memories absolutely, and most educated people believe them with a few reservations. Some of us take up a critical attitude even towards our own memories; we know that they not only sometimes drop things out, but that sometimes a sort of dreaming or a strong suggestion will put things in. But for all that memory remains vivid and real as no other knowledge can be, and to have seen and heard and felt is to be nearest to absolute conviction. Yet our memory of direct impressions is only the smallest part of what we know. Outside that bright area comes knowledge of a different order, the knowledge brought to us by other people. Outside our immediate personal memory there comes this wider area of facts, or quasi-facts, told us by more or less trustworthy people, told us by word of mouth or by the written word of living and of dead writers. This is the past of report, rumour, tradition and history, the second sort of knowledge of the past. The nearer knowledge of this sort is abundant and clear and detailed, remoter it becomes vaguer, still more remotely in time and space it dies down to brief, imperfect inscriptions and enigmatical traditions, and at last dies away, so far as the records and traditions of humanity go, into a doubt and darkness as black, just as black, as futurity. And now let me remind you that this second zone of knowledge outside the bright area of what we have felt and witnessed and handled for ourselves, this zone of hearsay and history and tradition completed the whole knowledge of the past that was accessible to Shakespeare, for example. To these limits man's knowledge of the past was absolutely confined save for some inklings and guesses, save for some small, almost negligible beginnings, until the nineteenth century began. Beside the correct knowledge in this scheme of hearsay and history a man had a certain amount of legend and error that rounded off the picture in a very satisfying and misleading way, according to Bishop Ussher, just exactly 4004 years B.C. And that was man's universal history—that was his all, until the scientific epoch began. And beyond those limits—? Well, I suppose the educated man of the sixteenth century was as certain of the non-existence of anything before the creation of the world as he was, and as most of us are still, of the practical non-existence of the future, or at any rate he was as satisfied of the impossibility of knowledge in the one direction as in the other.

But modern science, that is to say, the relentless systematic criticism of phenomena, has in the past hundred years absolutely destroyed the conception of a finitely distant beginning of things; has abolished such limits to the past as a dated creation set, and added an enormous vista to that limited sixteenth century outlook. And what I would insist upon is that this further knowledge is a new kind of knowledge, obtained in a new kind of way. We know to-day, quite as confidently and in many respects more intimately than we know Sargon, or Zenobia, or Caractacus, the form and the habits of creatures that no living being has ever met, that no human eye has ever regarded, and the character of scenery that no man has ever seen or can ever possibly see; we picture to ourselves the labyrinthodon raising its clumsy head above the waters of the Carboniferous swamps in which he lived, and we figure the pterodactyls, those great bird lizards, flapping their way athwart the forests of the Mesozoic age with exactly the same certainty as that with which we picture the rhinoceros or the vulture. I doubt no more about the facts in this further picture than I do about those in the nearest. I believe in the megatherium which I have never seen as confidently as I believe in the hippopotamus that has engulfed buns from my hand. A vast amount of detail in that further picture is now fixed and finite for all time. And a countless number of investigators are persistently and confidently enlarging, amplifying, correcting and pushing further and further back the boundaries of this greater past, this pre-human past that the scientific criticism of existing phenomena has discovered and restored and brought for the first time into the world of human thought. We have become possessed of a new and once unsuspected history of the world—of which all the history that was known, for example, to Doctor Johnson, is only the brief concluding chapter. And even that concluding chapter has been greatly enlarged and corrected by the exploring archæologist working strictly upon the lines of the new method, that is to say, the comparison and criticism of suggestive facts.

I want particularly to insist upon this, that all this outer past—this non-historical past—is the product of a new and keener habit of inquiry, and no sort of revelation. It is simply due to a new and more critical way of looking at things. Our knowledge of the geological past, clear and definite as it has become, is of a different and lower order than the knowledge of our memory, and yet of a quite practicable and trustworthy order, a knowledge good enough to go upon. And if one were to

speak of the private memory as the personal past, as the next wider area of knowledge as the traditional or historical past, then one might call all that great and inspiring background of remoter geological time, the inductive past.

And this great discovery of the inductive past was got by the discussion and rediscussion and effective criticism of a number of existing facts, odd-shaped lumps of stone, streaks and bandings in quarries and cliffs, anatomical and developmental details that had always been about in the world, that had been lying at the feet of mankind so long as mankind had existed, but that no one had ever dreamt before could supply any information at all, much more reveal such astounding and enlightening vistas. Looked at in a new way they became sources of dazzling and penetrating light; the remoter past lit up and became a picture. Considered as effects, compared and criticised, they yielded a clairvoyant vision of the history of interminable years.

And now—if it has been possible for men by picking out a number of suggestive and significant looking things in the present, by comparing them, criticising them, and discussing them, with a perpetual insistence upon *why*? without any guiding tradition, and indeed in the teeth of established beliefs, to construct this amazing searchlight of inference into the remoter past—is it really, after all, such an extravagant and hopeless thing to suggest that, by seeking for operating causes instead of for fossils and by criticising them as persistently and thoroughly as the geological record has been criticised, it may be possible to throw a searchlight of inference forward instead of backward and to attain to a knowledge of coming things as clear, as universally convincing and infinitely more important to mankind than the clear vision of the past that geology has opened to us during the nineteenth century?

Let us grant that anything to correspond with the memory, anything having the same relation to the future that memory has to the past, is out of the question. We cannot imagine, of course, that we can ever know any personal future to correspond with our personal past, or any traditional future to correspond with our traditional past. But the possibility of an inductive future to correspond with that great inductive past of geology and archæology is an altogether different thing.

I must confess that I believe quite firmly that an inductive knowledge of a great number of things in the future is becoming a human possibility. I believe that the time is drawing near when it will be possible to suggest a systematic exploration of the future. And you must not judge the practicability of this enterprise by the failures of the past. So far nothing has been attempted, so far no first-class mind has ever focussed itself upon these issues. But suppose the laws of social and political development, for example, were given as many brains, were given as much attention, criticism and discussion as we have given to the laws of chemical combination during the last fifty years—what might we not expect?

To the popular mind of to-day there is something very difficult in such a suggestion, soberly made. But here, in this Institution which has watched for a whole century over the splendid adolescence of science, and where the spirit of science is surely understood, you will know that as a matter of fact prophecy has always been inseparably associated with the idea of scientific research. The popular idea of scientific investigation is a vehement, aimless collection of little facts, collected as the bower bird collects shells and pebbles, in methodical little rows, and out of this process, in some manner unknown to the popular mind, certain conjuring tricks—the celebrated wonders of science—in a sort of accidental way emerge. The popular conception of all discovery is accident. But you will know that the essential thing in the scientific process is not the collection of facts, but the analysis of facts; facts are the raw material and not the substance of science; it is analysis that has given us all ordered knowledge, and you know that the aim and the test and the justification of the scientific process is *not* a marketable conjuring trick, but prophecy. Until a scientific theory yields confident forecasts you know it is unsound and tentative; it is mere theorising, as evanescent as art talk or the phantoms politicians talk about. The splendid body of gravitational astronomy, for example, establishes itself upon the certain forecast of stellar movements, and you would absolutely refuse to believe its amazing assertions if it were not for these same unerring forecasts. The whole body of medical science aims, and claims the ability, to diagnose. Meteorology constantly and persistently aims at prophecy, and it will never stand in a place of honour until it can certainly foretell. The chemist forecasts elements before he meets them—it is very properly his boast—and the splendid manner in which the mind of Clerk Maxwell reached in front of all experiment and foretold those things that Marconi has materialised is familiar to us all.

And if I am right in saying that science aims at prophecy, and if the specialist in each science is in fact doing his best *now* to prophesy within the limits of his field, what is there to stand in the way of our building up this growing body of forecast into an ordered picture of the future that will be just as certain, just as strictly science, and perhaps just as detailed as the picture that has been built up within the last hundred years to make the geological past? Well, so far and until we bring the prophecy down to the affairs of man and his children, it is just as possible to carry induction forward as back; it is just as simple and sure to work out the changing orbit of the earth in the future until the tidal drag hauls one unchanging face at last towards the sun as it is to work back to its blazing and molten past. Until man comes in, the inductive future is as real and convincing as the inductive past. But inorganic forces are the smaller part and the minor interest in this concern. Directly man becomes a factor the nature of the problem changes, and our whole present interest centres on the question whether man is, indeed, individually and collectively incalculable, a new element which entirely alters the nature of our inquiry and stamps it at once as vain and hopeless, or whether his presence complicates, but does not alter, the essential nature of the induction. How far may we hope to get trustworthy inductions about the future of man?

Well, I think, on the whole, we are inclined to underrate our chance of certainties in the future just as I think we are inclined to be too credulous about the historical past. The vividness of our personal memories, which are the very essence of reality to us, throws a glamour of conviction over tradition and past inductions. But the personal future must in the very nature of things be hidden from us so long as time endures, and this black ignorance at our very feet, this black shadow that corresponds to the brightness of our memories behind us, throws a glamour of uncertainty and unreality over all the future. We are continually surprising ourselves by our own will or want of will; the individualities about us are continually producing the unexpected, and it is very natural to reason that as we can never be precisely sure before the time comes what *we* are going to do and feel, and if we can never count with absolute certainty upon the acts and happenings even of our most intimate friends, how much the more impossible is it to anticipate the behaviour in any direction of states and communities?

In reply to which I would advance the suggestion that an increase in the number of human beings considered may positively simplify the case instead of complicating it, that as the individuals increase in number they begin to average out. Let me illustrate this point by a comparison. Angular pit sand has grains of the most varied shapes. Examined microscopically you will find all sorts of angles and outlines and variations. Before you look, you can say of no particular grain what its outline will be. And if you shoot a load of such sand from a cart you cannot foretell with any certainty where any particular grain will be in the heap that you make. But you can tell, you can tell pretty definitely, the form of the heap as a whole. And further, if you pass that sand through a series of shoots, and finally drop it some distance to the ground, you will be able to foretell that grains of a certain sort of form and size will for the most part be found in one part of the heap, and grains of another sort of form and size will be found in another part of the heap. In such a case, you see, the thing as a whole may be simpler than its component parts, and this I submit is also the case in many human affairs. So that because the individual future eludes us completely, that is no reason why we should not aspire to, and discover and use, safe and serviceable generalisations upon countless important issues in the human destiny.

But there is a very grave and important-looking difference between a load of sand and a multitude of human beings, and this I must face and examine. Our thoughts and wills and emotions are contagious. An exceptional sort of sand grain, a sand grain that was exceptionally big and heavy, for example, exerts no influence worth considering upon any other of the sand grains in the load. They will fall and roll and heap themselves just the same, whether that exceptional grain is with them or not. But an exceptional man comes into the world, a Cæsar or a Napoleon or a Peter the Hermit, and he appears to persuade

and convince and compel and take entire possession of the sand heap—I mean the community—and to twist and alter its destinies to an almost unlimited extent. And if this is indeed the case, it reduces our project of an inductive knowledge of the future to very small limits. To hope to foretell the birth and coming of men of exceptional force and genius is to hope incredibly, and if, indeed, such exceptional men do do as much as they seem to do in warping the path of humanity, our utmost prophetic limit in human affairs is a conditional sort of prophecy. *If* people do so and so, we can say, then such and such results will follow, and we must admit that that is our limit.

But everybody does not believe in the importance of the leading man. There are those who will say that the whole world is different by reason of Napoleon. But there are also those who will say the whole world of to-day would be very much as it is now if Napoleon had never been born. There are those who believe entirely in the individual man and those who believe entirely in the forces behind the individual man, and for my own part I must confess myself a rather extreme case of the latter kind. I must confess I believe that if by some juggling with space and time Julius Cæsar, Napoleon, Edward IV., William the Conqueror, Lord Rosebery and Robert Burns had all been changed at birth, it would not have produced any serious dislocation of the course of destiny. I believe that these great men of ours are no more than images and symbols and instruments taken, as it were, haphazard by the incessant and consistent forces behind them; they are the pen-nibs Fate has used for her writing, the diamonds upon the drill that pierces through the rock. And the more one inclines to this trust in forces, the more one will believe in the possibility of a reasoned inductive view of the future that will serve us in politics, in morals, in social contrivances, and in a thousand spacious ways. And even those who take the most extreme and personal and melodramatic view of the ways of human destiny, who see life as a tissue of fairy godmother births and accidental meetings and promises and jealousies, will, I suppose, admit there comes a limit to these things, that at last personality dies away and the greater forces come to their own. The great man, however great he be, cannot set back the whole scheme of things; what he does in right and reason will remain, and what he does against the greater creative forces will perish. We cannot foresee him, let us grant that. His personal difference, the splendour of his effect, his dramatic arrangement of events will be his own —in other words, we cannot estimate for accidents and accelerations and delays—but if only we throw our web of generalisation wide enough, if only we spin our rope of induction strong enough, the final result of the great man, his ultimate surviving consequences, will come within our net.

Such, then, is the sort of knowledge of the future that I believe is attainable, and worth attaining. I believe that the deliberate direction of historical study and of economic and social study towards the future, and an increasing reference, a deliberate and courageous reference, to the future in moral and religious discussion, would be enormously stimulating and enormously profitable to our intellectual life. I have done my best to suggest to you that such an enterprise is now a serious and practicable undertaking. But at the risk of repetition I would call your attention to the essential difference that must always hold between our attainable knowledge of the future and our existing knowledge of the past. The portion of the past that is brightest and most real to each of us is the individual past, the personal memory. The portion of the future that must remain darkest and least accessible is the individual future. Scientific prophecy will not be fortune telling, whatever else it may be. Those excellent people who cast horoscopes, those illegal fashionable palm-reading ladies who abound so much to-day, in whom nobody is so foolish as to believe, and to whom everybody is foolish enough to go, need fear no competition from the scientific prophets. The knowledge of the future we may hope to gain will be general and not individual; it will be no sort of knowledge that will either hamper us in the exercise of our individual free will or relieve us of our personal responsibility.

And now, how far is it possible at the present time to speculate on the particular outline the future will assume when it is investigated in this way?

It is interesting, before we answer that question, to take into account the speculations of a certain sect and culture of people who already, before the middle of last century, had set their faces towards the future as the justifying explanation of the present. These were the positivists, whose position is still most eloquently maintained and displayed by Mr. Frederic Harrison, in spite of the great expansion of the human outlook that has occurred since Comte. If you read Mr. Harrison, and if you are also, as I presume your presence here indicates, saturated with that new wine of more spacious knowledge that has been given the world during the last fifty years, you will have been greatly impressed by the peculiar limitations of the positivist conception of the future. So far as I can gather, Comte was, for all practical purposes, totally ignorant of that remoter past outside the past that is known to us by history, or if he was not totally ignorant of its existence, he was, and conscientiously remained, ignorant of its relevancy to the history of humanity. In the narrow and limited past he recognised, men had always been like the men of to-day; in the future he could not imagine that they would be anything more than men like the men of to-day. He perceived, as we all perceive, that the old social order was breaking up, and after a richly suggestive and incomplete analysis of the forces that were breaking it up, he set himself to plan a new static social order to replace it. If you will read Comte, or, what is much easier and pleasanter, if you will read Mr. Frederic Harrison, you will find this conception constantly apparent—that there was once a stable condition of society with humanity, so to speak, sitting down in an orderly and respectable manner; that humanity has been stirred up and is on the move, and that finally it will sit down again on a higher plane, and for good and all, cultured and happy, in the re-organised positivist state. And since he could see nothing beyond man in the future, there, in that millennial fashion, Comte had to end. Since he could imagine nothing higher than man, he had to assert that humanity, and particularly the future of humanity, was the highest of all conceivable things.

All that was perfectly comprehensible in a thinker of the first half of the nineteenth century. But we of the early twentieth, and particularly that growing majority of us who have been born since the "Origin of Species" was written, have no excuse for any such limited vision. Our imaginations have been trained upon a past in which the past that Comte knew is scarcely more than the concluding moment; we perceive that man, and all the world of men, is no more than the present phase of a development so great and splendid that beside this vision epics jingle like nursery rhymes, and all the exploits of humanity shrivel to the proportion of castles in the sand. We look back through countless millions of years and see the great will to live struggling out of the intertidal slime, struggling from shape to shape and from power to power, crawling and then walking confidently upon the land, struggling generation after generation to master the air, creeping down into the darkness of the deep; we see it turn upon itself in rage and hunger and reshape itself anew, we watch it draw nearer and more akin to us, expanding, elaborating itself, pursuing its relentless inconceivable purpose, until at last it reaches us and its being beats through our brains and arteries, throbs and thunders in our battleships, roars through our cities, sings in our music and flowers in our art. And when—from that retrospect—we turn again towards the future, surely any thought of finality, any millennial settlement of cultured persons, has vanished from our minds.

This fact that man is not final is the great unmanageable disturbing fact that rises upon us in the scientific discovery of the future, and to my mind at any rate the question what is to come *after* man is the most persistently fascinating and the most insoluble question in the whole world.

Of course we have no answer. Such imaginations as we have refuse to rise to the task.

But for the nearer future, while man is still man, there are a few general statements that seem to grow more certain. It seems to be pretty generally believed to-day that our dense populations are in the opening phase of a process of diffusion and aëration. It seems pretty inevitable also that at least the mass of white population in the world will be forced some way up the scale of education and personal efficiency in the next two or three decades. It is not difficult to collect reasons for supposing, and such reasons have been collected, that in the near future, in a couple of hundred years as one rash optimist has written, or in a thousand or so, humanity will be definitely and consciously organising itself as a great world State, a great world State that will purge from itself much that is mean, much that is bestial, and much that makes for individual dulness and dreariness, grey-

ness and wretchedness in the world of to-day. And although we know that there is nothing final in that world State, although we see it only as something to be reached and passed, although we are sure there will be no such sitting down to restore and perfect a culture as the positivists foretell, yet few people can persuade themselves to see anything beyond that except in the vaguest and more general terms. That world State of more efficient, more vivid, beautiful and eventful people is, so to speak, on the brow of the hill, and we cannot see over—though some of us can imagine great uplands beyond and something, something that glitters elusively, taking first one form and then another, through the haze. We can see no detail, we can see nothing definable, and it is simply, I know, the sanguine necessity of our minds that makes us believe those uplands of the future are still more gracious and splendid than we can either hope or imagine. But of things that can be demonstrated we have none.

Yet I suppose most of us entertain certain necessary persuasions, without which a moral life in this world is neither a reasonable nor a possible thing. All this paper is built finally upon certain negative beliefs that are incapable of scientific establishment. Our lives and powers are limited, our scope in space and time is limited, and it is not unreasonable that for fundamental beliefs we must go outside the sphere of reason and set our feet upon Faith. Implicit in all such speculations as this, is a very definite and quite arbitrary belief, and that belief is that neither humanity nor in truth any individual human being is living its life in vain. And it is entirely by an act of faith that we must rule out of our forecasts certain possibilities, certain things that one may consider improbable and against the chances, but that no one upon scientific grounds can call impossible. One must admit that it is impossible to show why certain things should not utterly destroy and end the entire human race and story, why night should not presently come down and make all our dreams and efforts vain. It is conceivable, for example, that some great unexpected mass of matter should presently rush upon us out of space, whirl sun and planets aside like dead leaves before the breeze, and collide with and utterly destroy every spark of life upon this earth. So far as positive human knowledge goes, this is a conceivably possible thing. There is nothing in science to show why such a thing should not be. It is conceivable, too, that some pestilence may presently appear, some new disease, that will destroy, not 10 or 15 or 20 per cent. of the earth's inhabitants as pestilences have done in the past, but 100 per cent., and so end our race. No one, speaking from scientific grounds alone, can say—that cannot be. And no one can dispute that some great disease of the atmosphere, some trailing cometary poison, some great emanation of vapour from the interior of the earth, such as Mr. Shiel has made a brilliant use of in his "Purple Cloud," is consistent with every demonstrated fact in the world. There may arise new animals to prey upon us by land and sea, and there may come some drug or a wrecking madness into the minds of men. And finally there is the reasonable certainty that this sun of ours must some day radiate itself towards extinction; that at least *must* happen, it will grow cooler and cooler, and its planets will rotate ever more sluggishly until some day this earth of ours, tideless and slow moving, will be dead and frozen, and all that has lived upon it will be frozen out and done with. There surely man must end. That of all such nightmares is the most insistently convincing.

And yet one doesn't believe it.

At least I do not. And I do not believe in these things because I have come to believe in certain other things,—in the coherency and purpose in the world and in the greatness of human destiny. Worlds may freeze and suns may perish, but there stirs something within us now that can never die again.

Do not misunderstand me when I speak of the greatness of human destiny.

If I may speak quite openly to you, I will confess that, considered as a final product, I do not think very much of myself or (saving your presence) my fellow creatures. I do not think I could possibly join in the worship of humanity with any gravity or sincerity. Think of it. Think of the positive facts. There are surely moods for all of us when one can feel Swift's amazement that such a being should deal in pride. There are moods when one can join in the laughter of Democritus; and they would come oftener were not the spectacle of human littleness so abundantly shot with pain. But it is not only with pain that the world is shot—it is shot with promise. Small as our vanity and carnality makes us, there has been a day of still smaller things. It is the long ascent of the past that gives the lie to our despair. We know now that all the blood and passion of our life was represented in the Carboniferous time by something—something, perhaps, cold-blooded and with a clammy skin, that lurked between air and water, and fled before the giant amphibia of those days.

For all the folly, blindness and pain of our lives, we have come some way from that. And the distance we have travelled gives us some earnest of the way we have yet to go.

Why should things cease at man? Why should not this rising curve rise yet more steeply and swiftly? There are many things to suggest that we are now in a phase of rapid and unprecedented development. The conditions under which men live are changing with an ever-increasing rapidity, and, so far as our knowledge goes, no sort of creatures have ever lived under changing conditions without undergoing the profoundest changes themselves. In the past century there was more change in the conditions of human life than there had been in the previous thousand years. A hundred years ago inventors and investigators were rare scattered men, and now invention and inquiry is the work of an organised army. This century will see changes that will dwarf those of the nineteenth century as those of the nineteenth dwarf those of the eighteenth. One can see no sign anywhere that this rush of change will be over presently, that the positivist dream of a social reconstruction and of a new static culture phase will ever be realised. Human society never has been quite static, and it will presently cease to attempt to be static. Everything seems pointing to the belief that we are entering upon a progress that will go on, with an ever-widening and ever more confident stride, for ever. The reorganisation of society that is going on now beneath the traditional appearance of things is a kinetic reorganisation. We are getting into marching order. We have struck our camp for ever and we are out upon the roads.

We are in the beginning of the greatest change that humanity has ever undergone. There is no shock, no epoch-making incident—but then there is no shock at a cloudy daybreak. At no point can we say, here it commences, now, last minute was night and this is morning. But insensibly we are in the day. If we care to look we can foresee growing knowledge, growing order, and presently a deliberate improvement of the blood and character of the race. And what we can see and imagine gives us a measure and gives us faith for what surpasses the imagination.

It is possible to believe that all the past is but the beginning of a beginning, and that all that is and has been is but the twilight of the dawn. It is possible to believe that all that the human mind has ever accomplished is but the dream before the awakening. We cannot see, there is no need for us to see, what this world will be like when the day has fully come. We are creatures of the twilight. But it is out of our race and lineage that minds will spring, that will reach back to us in our littleness to know us better than we know ourselves, and that will reach forward fearlessly to comprehend this future that defeats our eyes. All this world is heavy with the promise of greater things, and a day will come, one day in the unending succession of days, when beings, beings who are now latent in our thoughts and hidden in our loins, shall stand upon this earth as one stands upon a footstool, and shall laugh and reach out their hands amidst the stars.

THE WEST INDIAN AGRICULTURAL CONFERENCE, 1902.

THE fourth Agricultural Conference under the presidency of Dr. D. Morris, Imperial Commissioner of Agriculture for the West Indies, was held on January 4 to 6. The opening ceremony was attended by the Governor and the chief members of the military and civil services of the Colony. The delegates, some sixty in number, included representatives of the scientific and educational staffs of all the West Indian colonies.

The president delivered an address reviewing the work of the Department of Agriculture during its three years of existence. Under the head of sugar industry, experimental stations were at work at British Guiana, Barbados, Antigua and St. Kitts raising and testing large numbers of seedling canes, and extensive series of experiments were being carried out with manures. The insect and fungoid diseases of the sugar-cane were being carefully worked out, and schemes for central

factories at Barbados and Antigua were gradually taking shape. The diseases of cacao were receiving careful attention, and amongst subsidiary industries the best method of converting lime juice into citrate of lime was being investigated; attempts were being made to establish a trade in sweet potatoes between Barbados and London, to grow Irish potatoes for the London market, and to develop the onion industry in Antigua, Montserrat and Dominica; and plantations of the Central American rubber (*Castilloa elastica*) had been started at Trinidad and Tobago. A bee expert had been employed for several months to visit and advise bee-keepers, and lately an illustrated pamphlet containing information respecting bee-keeping in the West Indies had been published. Very favourable conditions existed in many of the West Indian colonies for raising horses, cattle and small stock, and efforts were being made to improve native breeds by the importation of stallion ponies, Maltese jacks and jennies, pedigree bulls, pigs, sheep, goats and poultry. The direct fruit trade recently established between Jamaica and the United Kingdom by means of a subsidised steamship service had proved entirely successful, and it was difficult to over-estimate the possibilities in this direction, in which many of the smaller West Indian islands might participate.

Agricultural education had formed an important part of the work done; courses of lectures in agriculture were being delivered in all parts of the West Indies to school teachers, and by this means the subject was being introduced into the primary schools. In the higher grade schools and colleges it was sought to establish lectureships in agricultural science; a lecturer had been provided by the Department at Barbados and Jamaica, and favourable reports had been received upon the results of their work. Seven agricultural scholarships had been founded, and it was hoped soon to be able to increase the number in order to afford opportunity to the most promising boys in the smaller islands to obtain sound agricultural teaching. Agricultural schools at St. Vincent, Dominica and St. Lucia had been established, at which seventy boys were being maintained for three or four years free of cost to their parents and carefully trained in the science and practice of agriculture. Attached to the schools were experiment stations, where the boys carry on all light operations and raise a portion of their own food. A series of lectures to planters had been given in Barbados the full text of which would shortly be published. Agricultural shows under the auspices of the Imperial Department of Agriculture were now regularly held at seven of the islands, and these shows were gradually drawing attention to the better cultivation and preparation of produce and bringing prominently into notice the varied resources of the islands.

Besides the journal of the Imperial Department of Agriculture (*West Indian Bulletin*), of which the last number of the second volume was in the press, twelve pamphlets, containing in the aggregate 417 pp., had been published since the last conference. These pamphlets contain information specially applicable to tropical conditions, and 30,000 copies are in course of being distributed. The principal subjects dealt with are:—"The General Treatment of Insect Pests" (first and second editions), "Scale Insects of the Lesser Antilles" (part i.), "Cultivation of Vegetables," "Hints for cooking Sweet Potatoes,"; "Bee-keeping in the West Indies," "Manures and Leguminous Plants at Barbados, 1898–1901," "Hints for School Gardens," "Seedling and other Canes in the Leeward Islands, 1900–1901," "Seedling and other Canes at Barbados, 1901." Of "Nature Teaching" (pp. 12 and 199) 2000 copies have been published and nearly all distributed. The Department contemplates the publication of a fortnightly paper, to be called the *Agricultural News*, containing hints and advice on all points of interest to the West Indies.

The sugar industry was the first subject taken up for discussion by the Conference; short papers were read by those engaged in sugar-cane experiments in the various colonies, summarising the progress made during the past year; a discussion ensued in which the agricultural representatives took an important part. While no seedling could be put forward at present to displace the old and well-tried varieties, it was felt that the progress made encouraged the view that the production of seedlings was destined to play an important part in the future existence of the sugar-cane industry in the West Indies. The accounts given of recent manurial experiments confirmed the importance of active nitrogenous manures, but tended to show that in many soils phosphatic manures did not increase the yield. The general consensus of opinion was in favour of supplementing the experimental station plots by trials upon a large scale on the estates, and this method has been already adopted in several colonies.

The proceedings included important papers by Mr. H. H. Cousins (Government chemist, Jamaica) and Mr. Joseph Shore (Jamaica), on "The Sugar Industry of Jamaica," and accounts of the life-history of the lady bird borer (*Sphenophorus sacchari*), by Mr. Maxwell Lefroy, and of "The Field Treatment of Cane Tops in reference to Fungoid Disease," by Mr. A. Howard.

On the second day, papers on agricultural education were read by Mr. A. B. McFarlane (principal of the Teachers' Training College, Jamaica), Mr. W. R. Buttenshaw (lecturer in agricultural science, Jamaica) and Messrs. J. E. Reece, J. A. Harbin and C. M. Martin, inspectors of schools at Barbados, Grenada and the Leeward Islands. An educational section, with the Bishop of Barbados as chairman and Mr. C. M. Martin as secretary, reported upon questions connected with agricultural teaching at primary schools. A chemical section, with Prof. J. B. Harrison (British Guiana) as chairman and Prof. J. P. d'Albuquerque (Barbados) secretary, reported upon chemical methods in sugar-cane work.

Papers were also read on "Suggestions for Regulating the Quality of Exported Fruit," by Mr. Sydney Olivier (Colonial Secretary, Jamaica), "The Preparation of Citrate of Lime," by Mr. Francis Watts (Government chemist, Leeward Islands), "Scale Diseases," by Mr. H. Maxwell Lefroy (entomologist to the Department), "Agricultural Boards," by Mr. Sydney Olivier, "The Preparation of Essential Oils," by Mr. Hart (Superintendent of the Botanic Gardens, Trinidad), "The Removal of Epiphytic Vegetation on the Stems of Cacao and Lime Trees," by Mr. A. Howard (mycologist to the Department), and "The Aloe Industry of Barbados," by Mr. W. G. Freeman (technical assistant to the Department).

J. P. D'ALBUQUERQUE.

THE LEONID SHOWER OF 1901.

IT now seems possible to give a brief review of the character of the Leonid shower which occurred last November, a considerable number of reports being available for the purpose. Certain other results obtained in various quarters of the globe doubtless still remain unpublished, but it is not likely that they will materially differ from those already before us.

In England the display of Leonids cannot be said to have been a conspicuous or a plentiful one, though it was decidedly stronger than in either of the years 1899 or 1900. Fortunately, the sky was clear on the nights following November 14 and 15, and a large number of observations were secured in different parts of the country. On the morning of November 15, Mr. H. Corder at Bridgwater watched the firmament for an hour and a half and saw 50 meteors, three-quarters of the number being Leonids, so that the horary rate of their apparition was about 25. Mr. E. C. Willis, of Norwich, found the hourly number 22 on the same morning, while on the following morning it was 18. Mr. J. R. Henry, of Dublin, observing from 1h. to 3.30, saw Leonids as bright as the first and second magnitude falling at the rate of 12 per hour. The maximum was apparently attained just before the morning twilight began to overpower the fainter stars. The horary numbers quoted above may be fairly considered to approximate the truth. It is true that some other observers saw fewer meteors, but as they were engaged in recording the individual paths, a considerable number must have altogether escaped their notice.

But the real maximum of the shower certainly occurred after sunrise in England; this is proved by observations from America, where the meteors were far more numerous, though the display was only of secondary importance. Mr. E. L. Larkin, at the observatory on Echo Mountain, S. California, counted 297 meteors on November 15, 4h. to 5h. a.m. (local time), so they were falling at the rate of 5 per minute. The maximum was at about 4h. 20m.–25m. a.m. One fireball left a streak for 14 minutes, and the meteors generally were very brilliant, two being estimated twenty times as bright as Venus, three ten times as bright, twelve five times as bright, and twenty-five equal to Venus. Forty were equal to Jupiter. At Ladd Observatory, Providence, the number seen was 2 per minute on the morning of November 15, while at several other places in the States the rate was 3 or 4 per minute between about 3h. 30m. and 5h. 30m. a.m.

At Carlton College, Northfield, Minn., it was estimated that four observers might have counted about 1600 meteors per hour. There was a marked falling off in numbers on the morning of November 16. Yet at two stations, according to newspaper reports, the shower was quite striking on the latter morning, for at Los Angeles one observer is said to have counted 385 meteors in the hour between 4h. and 5h. a.m., while at Phœnix 200 were seen in half an hour. It is highly probable, however, judging from the character of the shower as recorded at other stations, that in the two latter cases the observations were really made on the morning of the 15th and not on the 16th as stated in the newspaper accounts, which are often erroneous in such matters.

The maximum of the display must have occurred at about 11h. 30m. a.m. G.M.T. November 15, according to some of the best American descriptions. Possibly it may have been attained even later than this, for the morning twilight must have affected the observations to some extent. If the time of greatest frequency was after that stated, the phenomenon at its best could only have been observed from the Pacific Ocean, and it is not probable that we shall get any satisfactory reports from this region.

Though the shower was pretty active, it does not appear that photography has afforded any material assistance in recording its features. Plates were exposed at many observatories, but trails were absent upon them except in one or two isolated instances.

In England a number of meteors were doubly observed during the Leonid epoch, and their real paths have been calculated. In the following table are given the heights, &c., of 8 Leonids, of 1 Leo Minorid, of 1 δ Leonid, and of a remarkably slow-moving meteor from Cetus :—

Date. 1901.	G.M.T. h. m.	Mag.	Height at beginning. Miles	Height at ending. Miles.	Path. Miles.	Velocity per second. Miles.	Radiant point. α δ (° °)
Nov. 14	13 32	1 − >1	85	52	66	Rapid	156+32
	13 37½	2 − 1	77	57	38	Rapid	152+30
	13 42	♃ − ♀	81	67	67	55	174+20
	14 24	4 − 2	82	57	44	Rapid	152+25
	14 38	2 − 2	67	54	22	37	152+23
	15 7	3 − 1	95	55	60	Rapid	152+23
	15 23	>1 − ♃	72	47	36	72	151+25
	16 0	1 − >1	91	61	41	54	149+20
	16 7	1	86	60	35	Rapid	151+23
Nov. 15	13 8	1½ − 1	43	37	28½	7¾	38−21
	13 48	2 − ♃	76	59	37	37	151+21

The mean height of 8 true Leonids was 81 to 56 miles and the mean radiant-position $151^{\circ}\cdot2+23^{\circ}\cdot7$.

The place of the radiant found by Mr. Winslow Upton at the Ladd Observatory, Providence, was on November 15 a.m. $150\frac{3}{4}^{\circ}+21\frac{1}{2}^{\circ}$, and on November 16 a.m. $151^{\circ}+21\frac{1}{4}^{\circ}$.

The next return of the Leonids will be regarded in an interesting light, for 1902 will afford the 1000th anniversary of the first record of the shower (902). The moon will be full at the middle of November, but as the meteors of this swarm are often brilliant, some of them are likely to be distinguished in spite of the illuminated sky. There were showers of Leonids in 902, 1002, 1202 and 1602, and the revival of the display in 1901 encourages the hope that something may be seen of it in 1902, though the parent comet will be about three and a half years past its perihelion.

W. F. DENNING.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The 231st meeting of the Junior Scientific Club was held on January 31. Two papers were read, one by Prof. H. A. Miers, F.R.S., Magdalen, on gold-mining in Klondike, and the other, by Mr. H. L. Tidy, New College, on some curious sounds. The officers of the Club for this term are:—President, Mr. H. H. Cooke, New College; biological secretary, Mr. E. Burstal, Trinity; chemical secretary, Mr. S. P. Grundy, Balliol; treasurer, Mr. E. L. Kennaway, New College; editor, Mr. H. D. Davis, Balliol.

IN reply to a question in the House of Commons on Monday as to the approximate date of the introduction of the Education Bill promised in the King's Speech, Mr. Balfour said he was unable to give a date, but he hoped the Bill would be introduced before Whitsuntide.

CORRESPONDENCE classes in various branches of engineering have been successfully carried on in the United States for several years. Prof. Andrew Jamieson, late professor of electrical engineering at the Glasgow Technical College, has now established similar classes in Glasgow for students of electrical and machanical engineering. We are glad to notice that all students are advised to take a course of practical mathematics before devoting themselves to other subjects.

THE annual general meeting of the Association of Technical Institutions was held on Friday last in London. Lord Avebury, the president for the ensuing year, delivered an address in which he showed that the system of technical and higher education in Germany had been to the industrial advantage of the nation. If Britannia is to rule the waves she must be able to rule the steam engine and dynamo as well. Resolutions were adopted to the following effect:—(*a*) That this Association strongly approves the general principles on which the Government Education Bill of 1901 was based, and trusts that the Government will carry a Bill embodying these principles, with such amendments as may prove necessary, in the next session of Parliament. (*b*) That the Bill should prescribe that the residue under section 1 of the Local Taxation Account (Customs and Excise) Act, 1890, including any balance thereof which may remain unexpended at the end of the financial year, shall be applied for the purposes of education, and shall be administered by the education authority. (*c*) That an extension of the rating power by only 1d. in the pound, as was proposed in the Bill of 1901, would be wholly inadequate—especially in the case of the county boroughs—to defray the necessary additional charges in respect of secondary education which would fall upon the local authorities. (*d*) That it should be made a condition of the application of the residue under section 1 of the Local Taxation (Customs and Excise) Act, 1890, to the purposes of secondary education in general, that adequate provision shall first have been made for technical instruction, as was done in clauses one (1) and two (1) of the Duke of Devonshire's Education Bill of 1900. (*e*) That the Government should at once introduce and pass a Bill placing primary, secondary and technological education under the supervision of one local authority appointed as a rule for an area not less than that of a county or a county borough.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 23.—"On the Causation of the so-called 'Peripheral Reflex Secretion' of the Pancreas. (Preliminary Communication.)" By W. M. Bayliss, D.Sc. and Ernest H. Starling, M.D., F.R.S.

Introduction.—It has long been known that the introduction of acid into the duodenum causes a flow of pancreatic juice, and it has been shown recently by Popielski, and by Wertheimer and Le Page, that this flow still occurs after nervous isolation of duodenum and pancreas. Wertheimer also mentions that the flow can be excited by injection of acid into the jejunum, but not by introduction of acid into the lower part of the ileum. These authors conclude that the secretion is a local reflex, the centres being situated in the scattered ganglia of the pancreas, or, in the case of the jejunum, in the ganglia of the solar plexus (Wertheimer).

Results.—The secretion excited by introduction of acid into the jejunum cannot be reflex, since it occurs after extirpation of the solar plexus and destruction of all the nervous filaments passing to the isolated loop of jejunum. It also occurs after intravenous injection of 0·01 gramme atropin sulphate. It must therefore be due to direct excitation of the gland cells be a substance or substances conveyed to the gland from the bowel by the blood stream.

The exciting substance is not acid. Wertheimer has shown that injection of 0·4 per cent. HCl into the blood stream has no excitatory influence on the pancreas.

The secretion must therefore be due to some substance produced in the intestinal mucous membrane under the influence of the acid, and carried thence by the blood stream to the gland. This conclusion was at once confirmed by experiment.

When the mucous membrane of the jejunum or duodenum is exposed to the action of 0·4 per cent. HCl a body is produced which, when injected in minimal doses into the blood stream,

produces a copious secretion of pancreatic juice. This body, which for the present is termed *secretin*, is associated with another body with a pronounced lowering effect on the blood pressure. The two bodies are not identical, since acid extracts of the lower end of the ileum produce the pressure-lowering effect, but have no excitatory influence on the pancreas.

Observations indicate that *secretin* is probably a body of very definite composition, and of small molecular weight. Dr. Osborne is at present engaged in an investigation of its chemical characters and identity.

"On the Excretory Organs of Amphioxus." By Edwin S. Goodrich, M.A., Fellow of Merton College, Oxford. Communicated by E. Ray Lankester, F.R.S.

Linnean Society, January 16.—Prof. S. H. Vines, F.R.S., president, in the chair.—Mr. Alfred O. Walker exhibited some branches of cherry affected with a fungus disease caused by *Gnomonia erythrostoma*.—Mr. J. E. Harting exhibited some heads of wild sheep, together with photographs and lantern-slides, to illustrate a recent suggestion as to the use and value of spiral horns in feral species. Dr. George Wherry, of Cambridge, who originated the discussion and was present as a visitor, selected *Ovis nivicola* of Kamtschatka as a typical species to support his theory, and pointed out that while the horns were enormous, the ear was remarkably short, situated exactly in the axis of the spiral, and, as it were, at the apex of a hollow cone formed by the great spiral horn. This he regarded as a provision of Nature to enable the animal to hear better and to determine the direction of sounds when there is a mist or fog, the horn acting like an Admiralty megaphone when used as an ear-trumpet. Mr. Harting pointed out that the remarkably large spiral horns were peculiar to the male sex, and that if they were to be regarded as of use for the preservation of the species, the ewes, which required the most protection, would be in that respect defenceless. This would be especially the case with *Ovis nivicola*, the sexes of which, according to Dr. Guillemard ("Voyage of the *Marchesa*," vol. i. p. 214), lived apart in small herds for some portion of the year. It was a significant fact, also, that wild sheep, like other wild animals, posted sentries whilst feeding to prevent being surprised by their enemies, and it was the experience of those who hunted them that when approached the alarm was generally given by a ewe. He thought that wild sheep and goats, like deer, relied more upon their sense of sight and smell than upon their hearing, and that the large horns, like those of other ruminants, were simply weapons of defence against wild carnivora, and of offence against rivals during the breeding-season, as in the case of deer. Dr. Wherry, in reply, thought it would be found, in the case of ewes in which the horns were either absent or rudimentary, that the ears, by way of compensation, were much larger than those of the rams; but he had been unable to find anywhere a head of a female *Ovis nivicola* for examination.—Messrs. H. and J. Groves read a paper on the use of Linnean specific names. They showed that great diversity of practice existed in dealing with these names, and pointed out the necessity of arriving at some agreement as to their use as a first step towards uniformity in nomenclature. They grouped the Linnean specific names under the following heads:—(1) Those applied to distinct species fairly well understood in Linnæus's time, and still generally accepted. (2) Those which are now considered to include two or more species, combined by Linnæus owing to either (*a*) the imperfect knowledge of the plants at the time, or (*b*) the different ideas then and now as to the extent of species. (3) Those about which there is more or less doubt as to their proper application, owing to (*a*) the descriptions being imperfect, (*b*) the synonymy (often the most important part of the description) being contradictory, or (*c*) confusion due to changes made by Linnæus himself after publication. After discussing the various methods adopted and the difficulties connected with each, Messrs. Groves recommended that in doubtful cases, so far as possible, the description in conjunction with the reference to earlier authors should be relied on, always construing the species liberally, and that when the specimens in the Linnean herbarium or amendments in the second edition of "Species Plantarum" are at variance with this conception of the species, they should be disregarded. As regards group 2, they recommended that the name should be retained for the type if specified, or if not to the species which may be most fairly regarded as the type, and in the absence of such to the residuary species after others had been cut off; and as regards group 3, that unless the evidence is hopelessly vague, or contradictory, the names should be retained for the species for which the weight of evidence points to their having been intended. Specimens were exhibited of the plants which, following the practice advocated, would stand as *Hypericum quadrangulum*, L., *Epilobium alpinum* and *E. tetragonum*, L., and *Sparganium erectum*, L., also of the allied species in each case bearing on the question.

CAMBRIDGE.

Philosophical Society, January 20.—Prof. Macalister, president, in the chair.—On the question of "predisposition" and "immunity" in plants, by Prof. H. Marshall Ward, F.R.S. The author directed attention to previous work by himself and others which indicates that plants are not merely passive to the attacks of parasites, and especially referred to experiments with the rust fungi (Uredineæ) which clearly show that not only do these parasites vary and differ in their powers of adaptation to different hosts of the same species or genus, but the hosts exert definite reactions on the fungi. In particular, the results of a large series of infection experiments made by the author with the uredo of *Puccinia dispersa*, the brown rust of the bromes, were summarised. During the past summer more than 1800 such experimental infections were made on twenty-two varieties and species of Bromus, belonging to four out of the five subgenera. The infecting spores were derived from three different species of Bromus. The results show distinctly that not only does the power of the fungus to attack a given species of the flowering plant depend on the specific nature of the latter, but it also depends on the specific nature of the previous host on which the spores were produced. The conclusion is arrived at that specific predisposition and immunity in plants depend on similar internal mechanisms and conditions to those which determine the possibility or otherwise of cross-fertilisation, and just as this possibility varies and may be increased or diminished by inheritance in breeding, so may the capacity of resistance to infection vary and be increased or diminished in different races. It is probable that secretions of enzymes, chemotactic substances, toxins and antitoxins in the cell play a part in all such processes.—On the genito-urinary organs of dipnoan fishes, by Mr. Graham Kerr.—Further observations on the biological test for blood, by Mr. George H. F. Nuttall. The paper refers to studies of what the author terms "blood-relationship" amongst animals by means of test-tube reactions with various anti-sera. The results of the investigation of some 440 species of blood go to show that the biological test for blood may possess considerable value in relation to zoological study.

MANCHESTER.

Literary and Philosophical Society, January 21.—Mr. Charles Bailey, president, in the chair.—Mr. W. E. Hoyle made some remarks on a case of failure of concrete flooring strengthened by steel bands.—A paper, entitled "On *Xenophyton radiculosum* (Hick), and on a stigmarian rootlet probably related to *Lepidophloios fuliginosus* (Williamson)," was read by Prof. F. E. Weiss. He gave his reasons for regarding the fossil Xenophyton, described by the late Thomas Hick in 1891, as a stigmarian "root" or rhizome, which, on account of the peculiar structure of its vascular cylinder and of its massive and well-preserved middle cortex, he considered to be closely allied to the lepidodendroid stem known as *Lepidophloios fuliginosus*. He also described a stigmarian rootlet, which he considered to be related to Lepidophloios. This rootlet was further remarkable on account of the presence, in its well-preserved cortex, of a vascular branch similar to that described for stigmarian rootlets of a different type by Renault. Prof. Weiss stated that he had been able to confirm the occurrence of such branches from the central cylinder in several other stigmarian rootlets, in the collection of the Manchester Museum.

EDINBURGH.

Royal Society, December 16, 1901.—Prof. Geikie in the chair.—Dr. T. J. Jehu read a paper on a bathymetrical and geological study of the lakes of Snowdonia and eastern Carnarvonshire. It was clearly demonstrated that ice action had been an important factor in the formation of many of the valleys and lakes of the district, although at the same time it was also evident that other geological agents had been at work. The comparatively great depth of certain of the lakes, of which

sixteen had been studied in detail, left no doubt as to their glacial origin.

January 6.—Sir W. Turner in the chair.—A paper by Mr. F. Fraser, on a theoretical representation leading to general suggestions on the ultimate constitution of matter and ether, was communicated by Prof. Chrystal. The fundamental novelty was the conception of an atom of matter as a kind of ether bubble. The ether was supposed to be an assemblage of rapidly moving corpuscles rebounding after collision without loss of energy, and in this a spherical vacuity was produced forming the atom, the corpuscles in the spherical surface being kept circulating in the surface by the impacts of the corpuscles from outside, which on their part were unable to penetrate within the sphere because of the barrier of swiftly moving corpuscles in the surface. The author believed that this hypothesis gave the gravitation law of attraction between two neighbouring bubbles. The paper also contained speculations relating to valency in chemistry.—A paper was read by Dr. D. H. Scott on the primary structure of certain Palæozoic stems with the dadoxylon type of wood. The principal result of the investigation, as a whole, was to show that in a number of stems of Palæozoic age with secondary wood of the well-known dadoxylon type there were around the pith distinct usually mesarch strands of primary xylem, forming the downward continuation of the leaf-trace bundles. Hence, the anatomical structure typically represented by *Lyginodendron Oldhamii* proves to have been widely distributed among Palæozoic plants, and to have been common to stems which on other grounds would be reasonably referred to Cordaiteæ. Thus new links have been found connecting this gymnospermous family with the Cycadofilices, and through them with some primæval group of ferns.—Dr. Thomas Muir communicated a paper on a continuant resolvable into rational factors, and a note on selected combinations.—Dr. Hugh Marshall read a note on a suggested modification of the sign of equality in chemical notation, in which he proposed that in chemical equations representing actions which actually occur the sign of equality should be composed of singly barbed arrows arranged so as to differentiate the most important varieties of chemical action. The symbols suggested were : $\Longrightarrow$, $\rightleftharpoons$, $\Longleftrightarrow$, $=\!=\!=$, the first for irreversible actions, the second for reversible actions, such as dissociation, &c., the third for reversible actions with definite transition point (in which case the temperature might be stated above the symbol), and the fourth for reversible actions which, under the conditions of the experiment, are practically completed in the direction indicated, so that the reversible character of the action is not of immediate importance. It might also be used in doubtful cases.

PARIS.

Academy of Sciences, January 27.—M. Bouquet de la Grye in the chair.—An apparatus for measuring the variations of small zenithal distances, by M. G. Lippmann. The apparatus described makes the zenith visible in the field of observation as a small artificial star, which shows amongst the real stars. It possesses the advantages of requiring no special regulation or stability, and visual observations may be replaced by photography.—On some properties of the radiation from radioactive bodies, by M. Henri Becquerel. It has been shown in earlier papers that radium rays are divided into two groups in a strong magnetic field, one part being not affected and giving a strong impression on a photographic plate, the other being deviated in a manner similar to the kathode rays. No portion of the polonium rays is deviable. An analogous experiment has now been made with uranium. The times of exposure were necessarily very long, twenty and forty-two days in two experiments. The whole of the uranium rays appear to be deviated, the non-deviable portion, if it exists, being of an intensity which is negligibly small compared to the whole radiation. This would appear to show a fundamental difference between uranium and radium. It has been previously found that the dark radiation from radium is capable of transforming white into red phosphorus, and analogous experiments with uranium showed that the uranium rays possess the same property.—On the preparation of tantalum in the electric furnace and on its properties, by M. Henri Moissan. An alloy of niobium and tantalum was first prepared by reducing niobite with sugar charcoal in the electric furnace; this was then converted into fluotantalate and fluoniobate of potassium, and these salts separated by Marignac's method. The tantalic acid prepared in this way was then reduced with charcoal in the electric furnace in a graphite crucible. Metallic tantalum was thus obtained containing only a small quantity of carbon as impurity, as a brilliant metallic mass, with a crystalline fracture, of density 12·79. Its behaviour towards various chemical reagents is given in detail.—On a class of rational transformations, by M. Ivar Fredholm.—On the resolution of singular points of algebraic surfaces, by M. Beppo Levi.—The experimental definition of the different kinds of X-rays by radiochromometry, by M. L. Benoist. The unequal variations of transparency of two different bodies is utilised, when the quality of the X-rays changes, to define a series of qualities of rays by a series of relative transparencies, for example, of aluminium with respect to silver. The scale of rays thus constituted is always comparable to itself, when the two bodies and their thicknesses are defined.—On an apparatus for automatically registering discharges in the atmosphere, by M. J. Fényi. A coherer and a bobbin are inserted in the circuit of a Meidinger cell. A magnetised needle is placed in the centre of the bobbin, and this is deviated and closes the registering circuit when the coherer becomes conducting owing to a discharge.—On the vapour pressures of hydrogen selenide and the dissociation of its hydrate, by MM. de Forcrand and Fonzes-Diacon. The vapour pressures were measured at four points, $-42°$, -30, $0°·2$ and $30°·8$, and from these a curve was constructed. From this the heat of vaporisation was calculated by means of the Clapyron formula. A similar set of determinations was made for the hydrate.—On lithium antimonide and on the preparation of some alloys of lithium, by M. P. Lebeau. Lithium and antimony readily combine, giving rise to a large development of heat, but the violence of the reaction is so great that a definite compound could not be obtained in this way. But the electrolysis of a mixture of the chlorides of lithium and potassium with a kathode of antimony readily gives a definite crystallised antimonide of the formula $SbLi_3$. The same method can be applied to the preparation of a certain number of other alloys of lithium.—The action of copper hydrate on aqueous solutions of metallic salts, by M. A. Mailhe.—Contribution to the study of the aluminium-iron and aluminium-manganese alloys, by M. Léon Guillet.—On glyceroarsenic acid, by M. V. Auger. Arsenic acid and glycerol readily react, producing acid esters with the elimination of one or two molecules of water, but the product obtained is immediately hydrolysed on contact with cold water.—On the assimilation of lactic acid and of glycerol by *Eurotyopsis Gayoni*, by M. P. Mazé.—On the modifications of the segmentary organs of Syllis, and their functions, at the stage of reproduction, by M. G. Pruvot.—On the mechanism of the formation of the purple of molluscs, by M. Raphael Dubois. The production of the colour would appear to be due to two substances, one of which is a macrozymase, to which the name of purpurase is given. The action of light is necessary to the production of the purple.—On the physiological effects of the poison of the filaments and tentacles of the Cœlenterata, by MM. P. Portier and Charles Richet.—The apolar and closed divergent chains in ferns, by MM. C. Eg. Bertrand and F. Cornaille.—On the withering of vines caused by *Coepophagus echinopus*, by MM. L. Mangin and P. Viala.—The study of the daily variations of the meteorological elements in the atmosphere, by M. L. Teisserenc de Bort.—On the origin and age of the spring of Vaucluse, by M. E. A. Martel.

NEW SOUTH WALES.

Royal Society, December 4, 1901.—Prof. T. W. E. David, F.R.S., vice-president, in the chair.—The gums, resins and other vegetable exudations of Australia, by Mr. J. H. Maiden. The author gives a list of natural orders which in Australia yield both gums and resins, classifying them according as the gum or resin is the predominating substance. The paper contains a tentative list of those orders which yield kinos, and a list is given of those exudations which specially merit the attention of the research chemist. Then follows the main portion of the paper, which contains notes on all the exudations known to the author, arranged in botanical sequence.—On the principle of continuity in the generation of geometrical figures in homaloidal space of n-dimensions, by Mr. G. H. Knibbs. The author discussed the philosophical basis of the idea of the continuous generation of geometrical figures, and showed that we are compelled to admit the conceptional existence of a space of different orders, as well as dimensions, of infinity and zero, the interpretation of such being in all cases unambiguous.—Some theorems, concerning geometrical figures in space n dimensions, whose $(n-1)$ dimensional generatrices are n^{ic} functions of their position

on an axis, straight, curved, or tortuous, by Mr. G. H. Knibbs. In this paper the author showed that certain theorems developed in two previous papers might be extended greatly in generality, and were applicable to *quanta* determinations in n-dimensional space.—Rock-holes used by the aborigines for warming water, by Mr. R. H. Mathews. The author showed that the natives were in the habit of immersing heated stones in small quantities of water for the purpose of warming it for drinking, and in some cases to assist in cooking their food.—Some aboriginal tribes of Western Australia, by Mr. R. H. Mathews. Mr. Mathews also contributed an article on some aboriginal tribes of Western Australia, describing their divisions into intermarrying sections; lists of totems, comprising animals, plants and other natural objects, attached to each of the sections, were also given. The laws regulating marriage and descent were explained, together with a brief outline of the structure of the language. Mention was made of their legends, knowledge of the cardinal points, and customs of genital mutilation, the whole concluding with a comprehensive vocabulary.—Projects for water conservation, irrigation and drainage in New South Wales, by Mr. H. G. McKinney.

ST. LOUIS.

Academy of Science, January 6.—Mr. Henry W. Eliot, president, in the chair.—On behalf of herself and a considerable number of other persons, Mrs. William Bouton presented to the Academy a collection of 633 butterflies mounted on Denton tablets, on condition that the collection should be made accessible to the public. The following papers were presented by title:—New species of plants from Missouri, by Messrs. K. K. Mackenzie and B. F. Bush.—Revision of the North American species of Triodia, by Mr. B. F. Bush.—Prof. A. S. Chessin exhibited a gyroscope and explained how an accurately constructed and rapidly rotated gyroscope might be made to indicate the position of the meridian plane, the direction of the polar axis of the earth and the latitude of the place of observation, thus serving the purpose of the mariner's compass, but more accurately, because of the fact that the compass indicates the magnetic pole and not the true pole. The following formulæ pertaining to the subject were furnished:—

$$T=\pi\sqrt{\frac{A+C_1+A_2}{C\omega\Omega\cos\lambda}} \qquad T^1=\pi\sqrt{\frac{A+C_1+A_2}{C\omega\Omega}},$$

where T and T^1 are the durations of a complete oscillation of the gyroscope when its axis is made to remain in the horizontal and the meridian planes respectively; ω and Ω the angular velocities of rotation of the earth and the gyroscope respectively; A, A_1, A_2 and C, C_1, C_2 the equatorial and the axial moments of inertia of the gyroscope and the two rings on which it is mounted. From these formulæ the latitude (λ) of the place of observation is derived, namely:—

$$\cos\lambda=\frac{T^{12}}{T^2}.$$

—Prof. F. E. Nipher made a further statement concerning his results in the attempt to produce ether waves by the explosion of dynamite. He had obtained some results which seemed to show that magnetic effects could be thus produced.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 6.

ROYAL SOCIETY, at 4.30.—The Stratifications of Hydrogen: Sir William Crookes, F.R.S.—The Density and Coefficient of Cubical Expansion of Ice: Dr. J. H. Vincent.—On the Increase of Electrical Resistivity caused by alloying Iron with various Elements, and the Specific Heat of those Elements: Prof. W. F. Barrett, F.R.S.—Continuous Electrical Calorimetry: Prof. H. L. Callendar, F.R.S.

SOCIETY OF ARTS, at 4.30.—The Coal Resources of India: Prof. W. R. Dunstan, F.R.S.

LINNEAN SOCIETY, at 8.—On a Method of Investigating the Gravitational Sensitiveness of the Root-tip: F. Darwin, F.R.S.—An Extinct Family of Ferns: Dr. D. H. Scott, F.R.S.

CHEMICAL SOCIETY, at 8.—An Investigation into the Composition of Brittle Platinum: W. N. Hartley.—Conversion of l-Hydroxycamphene into β-Halogen Derivatives of Camphor: M. O. Forster.—Tetrazoline, Part II.: S. Ruhemann and H. E. Stapleton.—(1) The Solubilities of the Calcium Salts of the Acids of the Acetic Acid Series; (2) The Equilibrium between a Solid and its Saturated Solution at various Temperatures: J. S. Lumsden.—The Influence of Temperature on Association in Benzene Solution, and the Value of the Molecular Rise of Boiling Point for Benzene at Different Temperatures: W. R. Innes.—The Magnetic Rotation of Ring Compounds; Camphor, Limonene, Carvene, Pinene, and some of their Derivatives: W. H. Perkin, sen., F.R.S.—Polymerisation Products from Diazoacetic Ester: O. Silberrad.

RÖNTGEN SOCIETY, at 8.30.—A System of Radiography: E. W. H. Shenton.

FRIDAY, FEBRUARY 7.

ROYAL INSTITUTION, at 9.—The New Mammal from Central Africa and other Giraffe-like Animals: Prof. E. Ray Lankester, F.R.S.

GEOLOGISTS' ASSOCIATION, at 7.30.—Annual General Meeting.—Address on a Dozen Years of London Geology (Eocene, Chalk, and Underground): W. Whitaker, F.R.S., President.

MONDAY, FEBRUARY 10.

SOCIETY OF ARTS, at 8.—Personal Jewellery from Prehistoric Times: Cyril Davenport.

IMPERIAL INSTITUTE, at 8.30.—The Coloured Races in Australia: Hon. Sir Horace Tozer, K.C.M.G.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—The Ancient Kingdom of Kongo; Rev. Thomas Lewis.

TUESDAY, FEBRUARY 11.

ROYAL INSTITUTION, at 3.—The Cell: its Means of Offence and Defence: Dr. A. Macfadyen.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Port of Dundee: G. C. Buchanan.

WEDNESDAY, FEBRUARY 12.

SANITARY INSTITUTE, at 8.—Discussion on the Prevention of Small-Pox in the Metropolis: Opened by A. Wynter Blyth.

THURSDAY, FEBRUARY 13.

ROYAL SOCIETY, at 4.30.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Researches on the Electrical Conductivity and Magnetic Properties of upwards of 100 different Alloys of Iron: Prof. W. F. Barrett, F.R.S., and W. Brown.—On some Conclusions deduced from the preceding Paper: Prof. W. F. Barrett, F.R.S.

MATHEMATICAL SOCIETY, at 5.30.—On the Density of Linear Sets of Points: W. H. Young.—On Plane Cubics: Prof. A. C. Dixon.

FRIDAY, FEBRUARY 14.

ROYAL INSTITUTION, at 9.—Magic Squares and other Problems on a Chess Board: Major P. A. MacMahon, F.R.S.

PHYSICAL SOCIETY, at 5.—Annual General Meeting.—Address by the President, Prof. S. P. Thompson, F.R.S.—Mr. T. H. Littlewood will exhibit an Atwood's Machine.

ROYAL ASTRONOMICAL SOCIETY, at 3.—Annual General Meeting.

MALACOLOGICAL SOCIETY, at 8.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Some Public Health Aspects of the Question of Sewage Disposal: C. Johnston.

SATURDAY, FEBRUARY 15.

ROYAL INSTITUTION, at 3.—Some Electrical Developments: Lord Rayleigh, F.R.S.

THE CAMBRIDGE SCHOOL, AND A ZOOLOGICAL TEXT-BOOK.

Zoology, an Elementary Text-Book. By A. E. Shipley, M.A., of Cambridge, and E. W. McBride, M.A. (Camb.). D.Sc. (Lond.), of Montreal. Pp. 616 ; 349 text-figures. (Cambridge: University Press, 1901). Price 10*s.* 6*d.* net.

YET another elementary text-book of zoology ! The accumulation of facts in zoology during the last quarter of a century has been so overwhelming, that it becomes most difficult even to gauge the capacity of a book like the present, which deals broadly with the whole field. Choice of subject-matter is so wide, selection so difficult, that, in the endeavour to form an estimate of such a work, the mere determination on the part of the reviewer of a standard of comparison upon which to judge it, is in itself an arduous task. Let it be said, however, that the senior author of the present volume has an established reputation as a text-book writer, and that his previous achievements have led us to expect a sometimes thinnish mode of treatment. While in this we are not disappointed, under the joint authorship a very creditable book has been produced.

There are twenty-three chapters in all, the first of which is an "introduction" dealing with broad principles and first definitions. The contents and style of this are such as might be expected from a well-trained first-year man, and are apt to create a false impression of the rest of the book. This simplicity of treatment, however, is intentional, and expressive of the authors' scheme—for they tell us they have aimed at producing a book which can "be readily understood by a student who had no previous knowledge of the subject," and that the phraseology of the later portions of the work is relative to the earlier. Technical terms are explained as they occur, with roots in original Greek, and with fuller definitions where necessary. "Biogen" is introduced as denoting the living molecule. Histology, embryology and palæontology are intentionally placed at a discount, the treatment of classification, and of adult structure "as the outcome of function and habit," being the guiding principle. The several sections of the work treat each of selected individuals of a phylum, and the position and interrelationships of these in the general scheme of classification are for each section concisely stated, with a short diagnosis, in an accompanying table—an arrangement favourable to lucidity in the text, of which the authors have made the most.

Following the introduction are chapters on the Protozoa, Cœlenterata and Porifera. The Cœlomata are ushered in with an introduction special to themselves, and the leading Invertebrate phyla—viz. the Annelida, Arthropoda, Mollusca, Echinodermata, and Chætognatha—are in order dealt with. Seven chapters are next devoted to the Vertebrata ; and there are reserved for the four which conclude the volume the Platyhelminthes, Nemertinea, Rotifera and Nematoda, regarded as phyla which cannot be definitely asserted to be Cœlomata. A decidedly novel arrangement this ! but, under it, the Entoprocta (barely mentioned on p. 286) appear to have escaped adequate recognition, which is the more remarkable since the Chætognatha are accorded some three or four pages.

As a whole, the book is well written and up to date, and of the illustrations, those which are new are mostly good, those borrowed well chosen. Diagrams are given, especially where dealing with the circulatory system, and some of those of the venous channels might well be improved. There pervades the pages of the work a freshness of style and unconventionality which render them pleasant reading and attractive ; while, in the frequent allusion to the commonest occurrences of daily life and human affairs, the interest of the reader is assured. The chapters on the Porifera and Annelida may be cited as thin and inadequate, there being no mention of the horny sponges, of the genus Oscarella, or of the branchiate Oligochætes. Correspondingly slender is the treatment of the "Anacanthini" and Insectivora, the paragraphs upon which are miserably poor. Of definitions, that of the Cyclostomata may be instanced as erroneous, in the non-recognition of the Bdellostomoid forms possessed of more than seven pairs of gill pouches, and the statements concerning the "bile-duct" and the branchial basket-work (by comparison with p. 347), Dohrn having shown the "extra-branchials" to be extended gill-rays.

The description of the pancreas as a mere "outgrowth from the intestine" is insufficient, by non-recognition of its compound origin, now demonstrated for all gnathostomatous groups ; and, similarly, it is nowhere stated that the pulmonary artery is now known to be in all its forms a derivative of the fourth branchial arch. Nor is there mention of the highly significant transitional conditions of the heart (conus and its valves) occurring among the Clupesoces. Again, a most important point is lost in the ignoring of the circular type of the so-called semicircular canals, and the invariably saccular innervation of that which is posterior. And, finally, to pass to minor misstatements, we would remark that the forwardly directed process of the chelonian shoulder-girdle is a scapular derivative (proscapula) occurring only in these creatures and the Plesiosauria ; that the epipterygoid (columella) is not confined to the Lacertilia ; that the pre-hallux of the Batrachia is not definitely proved to be a digit homologous with the rest ; and that the bone which suspends the ophidian mandible is most certainly the supra-temporal.

We are also of opinion that too full an assurance is attached to the supposed quadripartite nature of the "arco-centrum." This, as a vertebral theory, was elaborated at Cambridge ; and we similarly find the Balanoglossoid, also favoured of the Cambridge school, set forth with all its best traditions—but why not Cephalodiscus and Rhabdopleura as well? They are not even mentioned.

One of the most noteworthy features of this book is the tardy recognition of the facts of comparative embryology and palæontology, and it is the more remarkable that the subordination of the former in a work written by two Cambridge men, should have been decided upon, at a time when embryological discovery of far-reaching significance is being made known. In this book the treatment of even larval forms is but casual and passing,

and were the discovery (now fifty years old) of the test-bearing protrochal stage of Dentalium, lately observed by Drew to be passed through by Yoldia and by Pruvot by a Dondersia, but recognised, we should not find the Chitons referred to a subclass of the Gastropoda and the "Solenogastres" accorded a class distinction. To this developmental stage, the discovery of which has dealt the death-blow to the idea of a Rhipidoglossan affinity of the Pelecypoda, and which, we trow, will ere long be extended to other groups, our authors should have directed attention. Had they done so, but three lines would not have sufficed for the Scaphopoda, and Spirula would not have been dismissed as a mere name.

Turning to palæontology, the non-recognition of the recent discovery in the Trilobites of nauplius characters deprives the authors' treatment of this larva of all force. And, similarly, had the Eurypterid forms recently described by Holm from the Russian Silurian, by Beecher from the Cambrian, and the Scorpionid genus Palæophonus, met with recognition, Limulus could not in justice have been once more relegated to the Arachnida. The absence in the present book of all mention of the Odontorinthes and Archæopteryx, of the Anomodontia, the Plesiosauria, and other leading fossil forms which might be named, is a serious omission, but even this does not excuse the non-reference to so important a group as the living Sphargidæ. Embryology and palæontology are branches of morphology coequal with the rest, and, so far as they reveal facts of primary significance, they should be dealt with as elementary subjects. Lack of appreciation of this principle is the weakest feature of the present work, which is, curiously enough, written with a special view to the requirements of the American student, who, of all beginners, is brought up in a palæontological air, and for whose benefit examples, wherever possible, are drawn from American as well as British animals.

Allowing for this serious defect, the book can be confidently recommended as well written and trustworthy, so far as it goes. It has been compiled at great pains, and its style leaves little to be desired. We wish it success and a speedy passage into a second edition; and, in anticipation of this, we would recommend to the authors' consideration the need of revision of such definitions as that of the endoderm cell (p. 48) as "tall"; of the blood-vessels (p. 89) as "chinks"; the replacement of the term "rudiment" on p. 259 by blastema; and certain other loosenesses which are self-evident. It is pertinent to this to remark that in some of their recent attempts at revised terminology, the zoologists of the Cambridge school have been none too successful. Thus, we note in the account of the life-history of the New Zealand reptile Sphenodon, given in the recently published natural history volume on "Amphibia and Reptiles," that the writer has substituted the word "æstivation" for what its discoverer rightly termed a hibernation. Is it possible that he has temporarily confused the southern summer with our own?

Of the illustrations, it may be said that figs. 266, 289 and 299 are examples which are poor, and might well be replaced; the statement that of the 32,000 "known species of Vertebrata" some 10,000 are Teleostei is surely excessive.

MATHEMATICAL TEXT-BOOKS IN THE UNITED STATES.

College Algebra. By J. H. Boyd, Ph.D. Pp. xxii+788. (Chicago: Scott, Foresman and Co., 1901.)

WE cannot obtain a complete view of the state of mathematical studies in a country merely by examining the text-books and treatises which are in vogue there; but we do, in this way, gain a good deal of information about the aims and standards of its mathematical teachers. Dr. Boyd's treatise illustrates very well the qualities and defects of American methods, and suggests a few general remarks, as well as particular criticisms, which may not be out of place.

First of all, it must be acknowledged that the excellences of the better class of mathematical authors in the United States greatly outweigh their deficiencies. The American student is alert and inquisitive; he is neither impervious to new ideas, nor unwilling to make experiments. Moreover, teachers and students alike regard mathematics in the proper spirit—as a science which has, indeed, a venerable history, but is at the same time living and progressive, with ever new developments and ever fresh applications to the needs of man. Many, if not most, of the leading mathematicians in the States have studied in Germany, and have thus become acquainted with the work of Kronecker and Weierstrass and the far-reaching influence of this upon function-theory and the foundations of analysis. In elementary geometry, too, they are not the slaves of tradition, as we are; and it is not impossible that they may ultimately give us the ideal class-book in geometry for which we are waiting.

Dr. Boyd, in his preface, accepts the modern standard of rigour, and in his choice of topics combines the indispensable rudiments with those developments and applications which are really important. The general scope of his book may be indicated by saying that Book I. deals with the fundamental laws of operation; II. with equations of the first degree; III. with indices, surds and complex quantities; IV. with quadratic equations; V. with proportion, progressions and logarithms; VI. with induction, permutations and combinations, and the binomial expansion for a positive integral exponent; VII. with limits and series; VIII. with the properties of determinants and the elementary theory of equations.

After proving the fundamental laws of operation for the cases where they are arithmetically intelligible, the author extends them by purely formal definitions; thus $(a-b)$ is defined by the formal equivalence $(a-b)+b=a$. This is unobjectionable, but seems to us to require more justification than Dr. Boyd explicitly gives. He appeals to the "principle of permanence of form," but this "principle" remains practically an assumption. No doubt it would be extremely tedious to give (what we think has never been done) a complete logical proof that the application of the generalised laws of operation never involves an inconsistency; still, something more might have been done to help the reader to apprehend the reasonableness of the assumption.

Again, Dr. Boyd is not always consistent with himself. Thus, in the chapter on fractions, he begins with the formal definition $\frac{a}{b}\times b=a$; he subsequently says that

4/7 means that a group of 7 things is regarded as a unit group out of which 4 things are taken; and finally gives a proof of the equivalence of 4/7 and 12/21 by means of a graduated scale. This is mixing up three different ways of looking at the matter in a fashion which is very likely to cause confusion. And, so far as his "group" definition goes, he gives it in an imperfect form which is not immediately applicable to improper fractions and which fails to account for the equivalence of a pair such as 4/7 and 12/21.

Another chapter to which we naturally turn is that on irrational numbers and limits. Irrational numbers are treated, after Cantor, as the limits of sequences; and the discussion is satisfactory so far as it goes, though it might well be made rather more complete and is occasionally rather illogical. Thus, for instance, in the early part of the chapter it is said that the ordinary rule for finding a square root, when applied to 2, leads to the inequalities

$$1<\sqrt{2}<2, \quad 1\cdot4<\sqrt{2}<1\cdot5, \quad 1\cdot41<\sqrt{2}<1\cdot42,$$

and so on. As thus stated, the proposition is a pure *petitio principii*. The sequence $(1, 1\cdot4, 1\cdot41, \ldots)$ is convergent, and may be rationally combined with other such sequences according to Cantor's rules; therefore it may be regarded as a number. By definition

$$(1, 1\cdot4, 1\cdot41, \ldots)^2=(1^2, 1\cdot4^2, 1\cdot41^2, \ldots),$$

and this sequence can be proved to be equivalent to 2; therefore $\sqrt{2}$ is an appropriate symbol for $(1, 1\cdot4, 1\cdot41, \ldots)$. We must not begin by assuming the existence of $\sqrt{2}$ as an arithmetical quantity. The proof that sequences obey the laws of operation is put very briefly, and when we turn to the chapter on surds, we find that such an equivalence as $\sqrt{2}\,.\,\sqrt{3}=\sqrt{6}$ is justified, not by the use of sequences, but by a reference to the purely formal law of indices. Here, again, we have a rather unfortunate association of two entirely different notions. If, for any purpose, we like to introduce a symbol θ such that $\theta^2=2$, every rational function of θ can be reduced, by formal processes, to the shape $P+Q\theta$, where P and Q are independent of θ; this is quite independent of the question whether θ can be properly regarded as a number or not; still less does it assign to θ its place in the arithmetical continuum.

Dr. Boyd's chapter on the binomial theorem for any exponent deserves attention, because, although it requires supplementing, it is novel, at least in a text-book, and may prove to be a good way of explaining the theorem to the college student. Let p/q be a positive rational fraction; then

$$(1+x)^{p/q}=\sqrt[q]{(1+px+\tfrac{1}{2}p(p-1)x^2+\ldots+x^p)}.$$

Now it can be shown, as Dr. Boyd indicates without going into detail, that we can, by a process which is, in fact, Horner's method, determine a polynomial

$$y=1+\frac{p}{q}x+c_2x^2+c_3x^3+\ldots+c_mx^m,$$

such that

$$(1+x)^p-y^q=R=Ax^{m+1}+Bx^{m+2}+\ldots+Lx^{qm},$$

where m is any positive integer assigned beforehand. The coefficients c_2, c_3, &c., are numerical, and it can be proved by the method of undetermined coefficients that

$$c_2=\tfrac{1}{2}p(p-q)/q^2, \ldots c_r=\left(\frac{p}{q}-r+1\right)c_{r-1}/r,$$

for $1<r<m+1$. By making m an indefinitely large integer, y becomes an infinite series, which is convergent for $|x|<1$. It remains to be proved that the sum of the infinite series y, when convergent, represents that branch of the function $(1+x)^{p/q}$ which reduces to 1 when x is zero. This last part of the proof Dr. Boyd has failed to supply or even to indicate; the need of it will be seen when it is observed that when y becomes an infinite series, the remainder R is also an infinite series, and it is essential to prove that, as m increases indefinitely, the limit of R is zero.

It will not be amiss to observe that these criticisms, offered with all friendliness and sympathy, are provoked just *because* Dr. Boyd aims at a high standard of logical exactitude. Many a worse book than his may be said to have fewer faults—faults, that is, which lie on the surface and can be pointed out in a few words. To write a really sound book on algebra, not incomprehensible to the ordinary college student, and not hopelessly unscientific when judged from the standpoint of contemporary analysis, is a very difficult task. But it is a worthy one; and the attempt justifies itself, even if it is not crowned with unqualified success. The reader of Dr. Boyd's book cannot fail to gain many fruitful ideas; if he has mathematical capacity he will very likely apprehend them in a substantially correct form, even when the author's exposition is not entirely rigorous.

To sum up, we find in this treatise, as in others of its class, much that is fresh, vital and stimulating; an interest in the progress of research, and in the development of new conceptions; together with a style that is neither frivolous nor pedantic. What we miss is, on the one hand, the German thoroughness which spares no pains to make the logical chain of an argument complete, and, on the other, our English dexterity of manipulation. This last faculty is not of much importance, truly, but is worth reasonable cultivation. It is strange to us, for instance, to find a whole page spent on the decomposition of x^4+px^2+q into a product $(x^2+\alpha)(x^2+\beta)$ without any reference to the fact that x^4+px^2+q is a quadratic in x^2. It is only fair to say that, in this instance, the context partly accounts for the phenomenon; but other examples of needlessly complicated work could easily be given.

A CANADIAN PIONEER IN SCIENCE AND EDUCATION.

Fifty Years of Work in Canada, Scientific and Educational. By Sir William Dawson, C.M.G., LL.D., F.R.S. Pp. viii + 308. (London and Edinburgh: Ballantyne, 1901.)

LITTLE more than a year has passed since the friends of science and of education in Canada had to mourn the death of Sir William Dawson. Though for the last six years of his life he had retired from his active official duties, his pen was not allowed to remain idle, but continued to throw off papers for scientific journals, addresses to societies and books of a more or less popular kind. One of the occupations of these closing years appears to have been the preparation of a sketch of his own career, which he left complete even to the dated preface

with instructions to his son to have it published as early as might be practicable after his death. Dr. Rankine Dawson has accordingly fulfilled the charge committed to him, and the result is a little volume entitled "Fifty years of Work in Canada, Scientific and Educational."

To those who were privileged with Sir William's friendship or acquaintance, the autobiography will recall many of the traits of his character, many little touches of manner and expression, and many of the moods of thought which showed themselves in his familiar talk. But to those who knew him not, the book will hardly reveal what manner of man he really was. Its readers will learn from it, indeed, that he must have been an enthusiastic student of nature, an upright and earnest and indefatigable teacher, an evidently kindly and genial man who with infinite patience and perseverance, and obviously with consummate tact and skill, fought and won the battle of higher education, for women as well as for men, in a colony where everything had to be begun from the beginning, and where the hindrances and opposition might have daunted a braver pioneer. It traces his life in outline from his boyhood at Pictou in Nova Scotia to his final retirement in the cottage at Little Métis, where, after a slight paralytic seizure in 1897, he quietly waited for the end. But it is no more than an outline, and though interesting as being his own account of himself, it is scarcely adequate as a lasting and final memorial of one who well deserves to be had in remembrance for his services to the geology and educational progress of Canada. Having been delayed till almost the end of his life, the autobiography lacks the freshness and fulness of recent recollection. Sir William met with many interesting and notable men in his time of whom one would fain have had his impressions—such pen-portraits as he probably gave in letters to his friends or family. One would like to know something more of his boyhood and the influences that drew him into the geological field. In a new country, before the days of railroads and coasting steamers, geological expeditions must often have brought a man into strange experiences. Then in regard to educational effort, which lay so close to Sir William's heart and to which he devoted so large a part of his strenuous life, he gives just information enough to make us long for more, that would fill in the details of an interesting struggle of which merely a sketch is given in the book. His published addresses and reports enable us to trace the general progress of his efforts, but naturally they lack the personal element, and the ordinary reader may sometimes fail to realise how much of the advance they chronicle was due to the initiation and persistent energy of the principal of McGill College himself.

Sir William Dawson's original contributions to science range over a considerable field, but the most important of them deal mainly with two departments of geology. He has done more than any other writer to make known the characters and the richness of the vegetation that preceded the luxuriant flora of the Carboniferous period. He speaks regretfully of the refusal of the council of our Royal Society to publish a paper and illustrations which he had prepared on the plants of the Old Red Sandstone, "thereby losing the credit of giving to the world the largest contribution made in our time to the flora of the period before the Carboniferous age." He adds that "a work which had cost me a large amount of time, labour and expense, and which I had looked upon as my *magnum opus*, was not adequately published and probably never will be."

The other branch of geological inquiry which Sir William prosecuted with characteristic energy related to the glacial deposits of Canada. After publishing a series of papers on the subject, he gathered up his results in more connected and popular form and published them in 1894 in his volume on "The Canadian Ice-Age." While glacialists have not generally accepted some of his views of the succession of events, they must acknowledge that recognition is due to the pioneer work by which the facts were first collected and arranged.

Allusion may be made here to another scientific question to which Dawson devoted a great deal of time and thought, though comparatively little reference to the subject occurs in the present volume. His name will always be associated with those of Logan and Carpenter in connection with the *Eozoon Canadense* of the Laurentian limestone. They regarded it as the earliest known trace of animal life, and as probably belonging to the foraminifera. Eventually their views were criticised and opposed, until now the prevailing opinion is adverse to the organic grade of the supposed fossil, but the principal of McGill College appears to have maintained his position to the end.

Sir William Dawson was an eminently religious man and a Christian of the most orthodox Presbyterian type. Though naturally peaceful, he was always ready to lay lance in rest and have a tilt with some adversary of his faith. He never accepted Darwinism. Three months after the appearance of the "Origin of Species" he published his first criticism of the modern doctrine of evolution. From that time, in articles, addresses and books, he continued to express more or less forcibly his dissent. The year before his death he summed up "The Case against Evolution," and in the autobiography which occupied his last days there are occasional indications of his unabated opposition to the opinions "as to the great instability of species, which have been so current among the leaders of the Darwinian evolution." His more popular volumes have had a wide circulation and have been of service in spreading an interest in geology and geological speculation.

The autobiography indicates in general terms that its author led a busy life, but no reader will gather from it an adequate idea of the extraordinary activity of that life. Even the ample list of separate papers which appears in the Catalogue of the Royal Society indicates only one side of his work. To that list must be added a voluminous series of lectures and papers on a wide range of educational, theological and other subjects, and quite a small library of separate books. And all this literary industry went on amid the incessant calls of an onerous official position. We trust that the autobiography may soon reach a second edition, and that advantage will then be taken of the opportunity to add such information as will hand down a fuller picture of the life and work of the late principal. A selection from his letters would be a welcome addition to the volume, likewise a list of his publications arranged year by year. Such a list, prepared by Dr. H. M. Ami, one of Dawson's pupils and a member

of the staff of the Geological Survey of Canada, was published in *The American Geologist* for July 1900. It needs careful revision, but might be made the foundation of a good bibliography. Sir William took so prominent a place in his time that there must be many hundreds of his friends and pupils who, while delighted to have his autobiographical sketch, would be glad to possess a fuller memorial of the man and of his achievements in the cause of science and of education. A. G.

THE FLORA OF INDIA ILLUSTRATED.

Annals of the Royal Botanic Garden, Calcutta. Vol. ix. Part i. *A Second Century of New and Rare Indian Plants.* (Calcutta: 1901.)

WITH the exception, perhaps, of Brazil, the flora of which has been more systematically illustrated, the flora of no country of very large area is so well pictorially illustrated as that of India. Disregarding the earlier publications of less precision, there are the works of Wight, Wallich, Roxburgh, Griffith, Royle and Hooker, and, later, of Brandis, Beddome and others, to say nothing of the very numerous scattered figures of Indian plants.

In 1888 Dr. (now Sir George) King, then Superintendent of the Calcutta Botanic Garden, commenced publishing a new series of quarto illustrations of Indian plants under the title cited above. The first volume contains all the Indian species of Ficus; the second the species of Artocarpus, Quercus and Castanopsis; both by King himself. The third volume is an illustrated monograph of the Indian species of the herbaceous genus Pedicularis, by Dr. D. Prain, the present Superintendent of the Calcutta Garden. The fourth volume is devoted to the Anonaceæ, by King; and the fifth contains a century of orchids, edited by Sir Joseph Hooker, and a century of new and rare Indian plants, by King and P. Brühl. The sixth volume is of a different character, and illustrates some of the microscopic researches of Dr. D. D. Cunningham. The seventh is a fully illustrated monograph of the Bambuseæ of India, by Mr. J. S. Gamble. The eighth volume, nominally, consists really of three thick volumes and comprises 448 coloured plates of Indian orchids, by Sir George King and Mr. R. Pantling. Each of these volumes has been more or less fully noticed in NATURE as it appeared.

The first part of the ninth volume contains a second century of new and rare Indian plants, by King and Prain and Mr. J. F. Duthie, Director of the Botanical Department, Northern India. Remarkable among these novelties are five beautiful species of Meconopsis (Papaveraceæ), thus nearly doubling the number of this essentially Himalayan genus. The specific names, *grandis*, *superba*, *bella* and *primulina*, are suggestive of the ornamental characters which these herbaceous plants possess in a high degree. Unfortunately they are rather difficult to cultivate, but one or two species succeed very well in the rock-garden at Kew. Two or three very fine species of Meconopsis are among the comparatively recent discoveries in western China, and *M. horridula* is one of the most generally dispersed plants in the meagre flora of Tibet, at altitudes of 12,000 to 17,000 feet. Indeed, all the Asiatic species inhabit high levels, and some of them reach the upper limit of phanerogamic vegetation. The only outliers of the genus are *M. Cambrica*, the lowly Welsh poppy, and *M. heterophylla*, a native of California. One of the finest of the species figured in the "Annals," *M. grandis*, is only known from Jongri, in Sikkim, where it is cultivated at altitudes of 10,000 to 12,000 feet, not for its beauty, however, but for the oil obtained from its seeds. Figures are given of three other pretty Papaveraceæ, namely, *Cathcartia lyrata*, *C. polygonoides* and *Chelidonium Dicranostigma*.

From a botanical standpoint the drawings are very good, and the lithography deserves to be rated as excellent. Nearly the whole is the work of native artists.

We have made a point of the new Papaveraceæ, but there are other equally interesting subjects illustrated in this part. New Rutaceæ, Burseraceæ and Sapindaceæ, chiefly by King; Leguminosæ and Labiatæ, by Prain; and alpine Himalayan plants, including new species of Primula, by Duthie.

There is also a proposed new genus of Orobanchaceæ, concerning which particulars of its affinities might have been given. It is named *Gleadovia ruborum*, and was discovered by Messrs. Gleadow and Gamble growing on the roots of *Rubus niveus*, in fir woods, in the North-west Himalaya. The great value of such a publication as the "Annals" can only be appreciated by the working botanist, and it will be of general interest to know that plants of special economic interest will be a feature in the next part. W. BOTTING HEMSLEY.

OUR BOOK SHELF.

Essais sur la Philosophie des Sciences. Analyse, Mécanique. By C. de Freycinet. Second edition. Pp. xiii + 336. (Paris: Gauthier Villars, 1900.)

A GOOD book on the philosophical aspect of space, time, mass and force is rare. M. de Freycinet has produced a work that is both readable and worth reading. It opens with a chapter on space and time in which the essential differences of these two fundamental conceptions are discussed, and the impossibility of forming a quantitative estimate of time except by artificial means is clearly pointed out. The next chapters deal with the notions of infinity, of continuous magnitude, of limits, of infinitesimals and of differential coefficients. In considering the reality of such conceptions, the author is careful to distinguish between reality in a mathematical and in a physical sense, and to point out that reality in the first sense does not necessarily imply reality in the second. Thus the solutions by the calculus of many problems in mathematical physics are based on the assumption that both space and matter are continuous and capable of indefinite subdivision, and these solutions are none the less correct although other phenomena teach us that matter is to be regarded as built up of discrete molecules.

The second part deals with the quantities occurring in dynamics, the laws of motion, the principle of conservation of energy. In it M. de Freycinet has endeavoured in the present second edition to throw greater light on the debated question as to the relative parts played by Galileo and Kepler in the discovery of the laws of motion. According to him these laws consist of (1) the law of equality of action and reaction, due to Newton; (2) the law of inertia, now attributed to Kepler; (3) the law of independence of movements due to Galileo, according to which the relative motion of the parts of a system is unaltered by impressing a common velocity on them; and (4) the law of equivalence of work and heat due to Mayer

and Joule. If this last law, which practically amounts to a definition of *heat* as a dynamical quantity, coupled with a statement of the principle of conservation of energy, is to be admitted among the laws of motion, why should the second law of thermodynamics be excluded? In chapter vii. the author discusses the possible causes of loss of energy in the universe, but he might with considerable advantage introduce something about the degradation of available energy. This principle has an important bearing on the question of the infinity of the universe and the infinity of time. A finite universe cannot have existed for an infinite time past, radiating its energy into infinite space, but as soon as the principle of degradation of available energy is assumed, a similar difficulty as to infinity of time is found in dealing with an infinite universe, all of whose energy ultimately tends to be dissipated in the form of heat, and all of whose parts tend to a common temperature.

There is thus ample room for M. de Freycinet to write a further essay on the irreversible phenomena of Nature. There is another interesting field of study which he now mentions only in a footnote on p. 43, namely the existence of imaginary quantity and the remarkable fact that the generalisation of the laws of ordinary algebra requires the introduction of only one imaginary symbol. But, as the author points out, in the present state of science it is impossible for one man to survey our knowledge of more than a limited portion of natural phenomena. M. de Freycinet has given his readers much to think about in the domains of infinitesimal analysis and rational mechanics, and, moreover, this is written in a style which makes the book easy to read.

The Thermal Measurement of Energy. Lectures delivered at the Philosophical Hall, Leeds, by E. H. Griffiths, M.A., F.R.S. Pp. viii+133. (Cambridge: University Press, 1901.)

THIS little book consists of an account of four lectures, delivered to teachers by the author, at the request of the Technical Instruction Committee of the West Riding County Council. The author remarks that "The reflection that hundreds of such teachers should have been willing to sacrifice their Saturday afternoons to the study of certain physical measurements which did not even possess the charm of novelty may somewhat lighten the gloomy prospect sketched for us by those who hold pessimistic views as to the future of Intermediate Scientific Education in this country."

In attempting to render interesting a discussion of the thermal measurement of energy, Mr. Griffiths undertook a difficult task, which he has discharged admirably. There is no trace of the "popular lecturer" pure and simple; in his treatment of the subject success is due, not to an adroit avoidance of difficulties, but to the straightforward and conscientious attention given to every point of importance. In the first lecture, a number of well-chosen experiments are used to illustrate the conversion of work into heat. The second lecture is occupied with a consideration of the first and second laws of thermodynamics; incidentally the student is made acquainted with some of the difficulties attending thermometric determinations. In the third lecture an account is given of the principal methods which have been employed to determine the mechanical equivalent of heat. In this connection students will welcome the description of Reynolds and Moorby's determination, which has not as yet been dealt with in the text-books; it is to be regretted that more space could not be devoted to this valuable piece of work. A good account is given of Mr. Griffiths' own experimental test of the validity of the system of electrical units. Lecture iii. closes with a description of the recent experimental work of Callendar and Barnes on the variation in the specific heat of water.

The fourth lecture possesses very great interest. After remarking that text-books frequently give the specific heats of the metals to four of five decimal places, it is pointed out that these results necessarily depend for their accuracy on the values assumed for the specific heat of water at various temperatures. Generally speaking, authors content themselves with referring to Regnault's results, without, however, consulting Regnault's original papers. It appears that *only two* experiments were performed by Regnault for temperatures below 107°, and these were undertaken merely to test the working of the apparatus used, and Regnault himself attached no importance to them. As a matter of fact, Regnault performed a series of determinations of the changes in the specific heat of water *over the range* 107° *to* 190° C. After discussing the results, he stated what the nature of the variation between 0° and 100° would be if deduced by extrapolation from the experimental curve obtained at the higher range. Later investigations have proved these conclusions to be at fault, so that much otherwise unimpeachable experimental work relating to specific heats requires revision, and in many cases the data necessary for this purpose are not given by the authors.

It is finally recommended that the specific heat of water between 17° and 18° C. shall be defined as of unit value; this also amounts to defining the mean specific heat of water between 0° and 100° as of unit value. In that case the most probable value of the mechanical equivalent of heat is equal to $41 \cdot 84 \times 10^6$. E. E.

Instruments et Méthodes de Mesures Electriques Industrielles. By H. Armagnat. Pp. iii+614. (Paris: C. Naud.)

FEW, perhaps, realise how much electrical engineering owes its rapid development to the ease and precision with which the measurements it needs can be made. Yet it is this which renders it so amenable to mathematical and scientific treatment, and it is very largely owing to the fact that it can be so treated that it has progressed so rapidly. The manufacture of instruments has in many instances led rather than followed the development of the engineering side of the electrical industry. The practical engineer finds ready to his hand instruments for almost every conceivable purpose he may require, and it cannot be questioned that it is of the highest importance that he should properly understand their construction and limitations. M. Armagnat's book should therefore prove exceedingly useful to such men as a work of reference in which they can find a full discussion of the principles underlying the construction of the tools they use. As the author points out in his preface, beginners, and those also who habitually use instruments, are too often ignorant of their powers and of the proper way of treating them. Many mistakes, often of a serious nature, would be avoided if this state of affairs were remedied.

M. Armagnat describes both the instruments which are only to be found in electrical laboratories and those which are in daily and extended commercial use. It is the part of the book dealing with the commercial instruments which will commend itself more particularly to the practical engineer. The author has wisely confined himself to describing typical instruments of each class, and has refrained from giving descriptions of the numerous different examples of the type. Perhaps, however, an improvement would be introduced if instruments of different makes were compared, as this would serve as a useful guide to those who are in doubt as to what to purchase most suitable for their particular requirements. Valuable information is given as to the best methods of installing delicate instruments, of securing good illumination, freedom from vibration and outside disturbance, and of carrying out observations and measurements. The chapters devoted to these subjects add very greatly to the usefulness of the book, especially from the point of

view of the student. It may be said finally that the book is not merely useful as a work of reference, but it is thoroughly readable throughout. M. S.

Pleasures of the Telescope. By Garrett P. Serviss. Pp. vi + 200. (London: Hirschfeld Brothers, 1901.) Price 6*s*. net.

THIS book is the result of the collection under one cover of a series of articles originally published in serial form, after considerable revision and insertion of matter necessary to bring the information up to date.

Chapter i. deals in a very interesting manner with advice on the choice of telescopes, special characteristics of refractors and reflectors, principles underlying the achromatic corrections of refractors, and methods of testing the performance of astronomical instruments.

Following this, six chapters are devoted to a series of descriptions of the constellations, numerical particulars being furnished for all the more interesting objects. A very liberal supply of star-maps—twenty-six—serves for the identification of all the objects mentioned in the text.

The main features of the planets are also described, small cuts indicating the details to be seen with powers usually at an amateur's command. Four charts of the moon are given, showing the more important formations only, so as to avoid the confusion inseparable from the complete maps. This section is made exceedingly interesting by the various formations being compared with each other, the reader passing from one to another much more readily than by merely going over a list of objects. Users of the book will recognise the treatment of the subject as similar to that in "Astronomy with an Opera-glass," by the same author, and it will doubtless be welcome to many workers who only require information concerning objects within reach of the instruments usually possessed by amateurs; but the size of telescope catered for, of 5 inches aperture, is sufficiently large to render the information of service to the more advanced astronomer as well. There is only one slight criticism which may be suggested regarding the preparation of the star maps. On these there is no indication of either the coordinates of right ascension or declination. In actual practice, either in learning the constellations or in passing from one map to another, it is impossible to over-estimate the help which is furnished by the graduated position lines. The legibility and general arrangement of the maps, however, are excellent and add greatly to the value of the book, which there can be no hesitation in recommending to the notice of all interested in observational astronomy. C. P. B.

Introductory Physics for Irish Intermediate Schools. By R. A. Gregory and A. T. Simmons, B.Sc. Pp. ix + 218. (London: Macmillan and Co., Ltd., 1901.) Price 2*s*.

THIS little book, as its emerald-green covers and title suggest, is for the use of Irish boys and girls preparing for the examination on the new syllabus in introductory physics issued by the Department of Agriculture and Technical Instruction. A glance at the book shows that Irish physics is the same as English, and those familiar with the other books prepared by the same authors will find here practically the same exercises. S. S.

Algebraical Examples. By H. S. Hall, M.A. Pp. viii + 172. (London: Macmillan and Co., Ltd.) Price 2*s*.

IT will be a convenience to many teachers to possess this collection of algebraical exercises to supplement those given in Hall and Knight's "Algebra for Beginners" and "Elementary Algebra," up to quadratic equations. The exercises are carefully graduated, and are classified so that the teacher can easily select those referring to the subject with which he is dealing. In addition, there are a number of test-papers containing miscellaneous examples to test the pupil's grasp of the principles of algebra in which he has been exercised.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The FitzGerald-Lorentz Effect.

IN the January number of the *Philosophical Magazine* I published a discussion of the general theory underlying the experiment of Messrs. Michelson and Morley on the drift of the æther. As one result, it appeared that the effect to be expected in their special case was just the opposite of that usually supposed, and that consequently the FitzGerald-Lorentz explanation of the observed null effect would not hold. Mr. H. M. Macdonald has pointed out the source of this discrepancy in an algebraic slip in my paper; when this is corrected, the result comes into agreement with the special case treated by Michelson and Morley. The exact effect on the displacement of the interference-bands arising from a vertical component in the æther-drift has not been hitherto directly considered. It is probably null; but this requires verification, which I hope to be able to take up shortly on the basis of my analysis. As the question stands at present, the corrected result shows that the FitzGerald-Lorentz shrinkage would completely annul the shift when the drift is tangential. Although Dr. Larmor has not directly discussed the effect of an oblique drift in his "Aether and Matter," I understand from him that he has come to the conclusion (*cf. loc. cit.* § 34) that complete annulment results in all cases on the FitzGerald-Lorentz hypothesis. I think further discussion on the lines of my own method of analysis will verify that this is the case.

Meantime I send this intimation in order that others may not spend time in tracking out a discrepancy which has already been cleared up. W. M. HICKS.

University College, Sheffield, February 10.

Birds Attacking Butterflies.

ON July 22, 1901, a dull, sunless day, I pointed out to Prof. Gotch a fine fresh male specimen of the "Holly Blue" (*Lycaena argiolus*) at rest on the leaf of a shrub behind the Oxford University Museum. Touching it with my finger, the butterfly rose and fluttered feebly along the curved walk in the Parks. At that moment a swallow (or a martin) came down the walk from the opposite direction at full speed. It must have seen the butterfly fluttering towards it from a considerable distance; for with the most perfect ease and control it diverted its course and took the insect in its sweep. I felt, as I saw it, that only by good fortune was it possible thus to obtain the most direct evidence of events which are probably continually occurring.

There are, however, other means by which evidence can be obtained. One is the examination of the crops of dead birds. Although we should be sorry for British birds to be killed with this object (except in special circumstances), it is much to be hoped that the observations will be made when birds are killed, whether accidentally or otherwise. Mr. R. Newstead, of the Chester Museum, has done excellent work in this way; but there can be no doubt that, taking the country as a whole, only an insignificant proportion of the obtainable evidence is utilised.

Another line of evidence is afforded by specimens of butterflies which have their wings injured in a manner which is inconsistent with any interpretation except the snip of a bird's beak. Thus it is common to find fresh and unworn specimens with a notch or tear on the right side which exactly fits a corresponding injury on the left side, indicating that the wings had been torn when they were in contact. In one extreme instance, presented to the Hope Department by Dr. F. A. Dixey, a deep little notch had been cut out of all four wings of a "Red Admiral" (*Vanessa atalanta*), the four injuries exactly coinciding in the true position of rest adopted by this insect.

Oxford, February 2. EDWARD B. POULTON.

P.S.—Mr. W. Holland, of the Hope Department, tells me that about the middle of June 1901 he saw a swallow swoop down from a great distance and catch a white butterfly (almost certainly *Pieris rapae*) flying in front of the Museum. The bird took the insect in a single sweep and then dextrously avoided a

collision, which seemed almost inevitable, with the roof of the "Glastonbury Kitchen." Directly after the seizure of the butterfly, Mr. Holland saw the wings fluttering to the ground, evidently cut through at their bases by the beak.—E. B. P.

I CAN corroborate the statement that the house-sparrow frequently pursues and captures the large white cabbage butterfly.

Probably the kestrel preys extensively on the emperor moth, whose wings I have seen lying at the base of the small hummocks formed by the *Juncus squarrosus* on the Orkney moorlands. These tufts were much used as resting places by kestrels and hen harriers, but as neither hawk is capable of catching a bird on the wing, the moths were presumably captured while at rest.

The black-headed gull feeds on the common ghost moth. Regularly every season, during many years, I saw some half dozen or more of these gulls flying backwards and forwards, about three feet above the ground, over the grass in front of my house, hawking after the white oscillating ghost moths in the long summer twilight of a calm Orcadian evening.

W. IRVINE FORTESCUE.

7, Bon Accord Square, Aberdeen, February 3.

The Severn Bore.

IN NATURE of January 23 there is an interesting illustration of the Severn Bore, as photographed by Dr. Vaughan Cornish. If I understand the note rightly, the bore took a little more than a minute to travel 500 yards, and this gives a rate of almost exactly seventeen miles an hour at the given locality.

On March 13, 1891, Mr. T. H. Thomas, R.C.A., and I measured the velocity of the bore between a point on the right bank of the river near the King's Head Inn (which is sixty yards north of the sixth milestone from Gloucester on the high road to Newnham) and a point further up on the right bank of the river, near Denny Farm and opposite to the fifth milestone from Gloucester.

The second hands of two watches were timed exactly together, and we found that the bore reached the first observer at 10h. 24m. 45s., a.m., and the second at 10h. 27m. 48s., a.m., the interval being 183 seconds.

Measured on the six-inch ordnance map, the distance along the central line of the river is 4750 feet. The velocity was therefore $17\frac{7}{10}$ miles an hour for the part of the river observed. The river channel there is of a fairly uniform width of 250 feet.

The date chosen was that of the second highest tide of the spring equinox. At 10h. 25m. the height of the bore, above low water level, as measured by a post close to the river bank near the King's Head Inn, was 4ft. 10in. As the bore passed on, the level sank to 3ft. 4in. By 10h. 30m. the water following the bore reached a height of 5ft. 4in. At 10h. $32\frac{1}{2}$m. the height was 6ft. 4in., and at 10h. 34m. the water covered the post, the top of which was nearly 7ft. above low water level. There was thus a rapid rise of the river in the rear of the bore. As seen in mid-stream, the height of the crest of the bore seemed only about 3ft. above that of the water in front of it.

There was a gentle breeze from the north-east. Had there been a south-westerly gale blowing up stream, no doubt the phenomenon wou'd have been much more impressive, but it is of interest to record observations made under fairly normal conditions.

The rushing sound, heralding the advancing wall of water, was audible for some distance. The crest of the bore was whitened by a fringe of foam, and a good deal of spray was thrown up on the banks, where the water of the wave appeared to be higher than, and somewhat in advance of, that in the middle of the river.

A small boat in the path of the bore suffered no inconvenience beyond a slight tossing. The late Frank Buckland greatly exaggerated when he described the bore as "the greatest natural phenomenon in the British Isles," and stated that its pace was equal to that of an express train. Dr. Cornish (NATURE, vol. lxii. p. 127) estimates the velocity of the bore, on April 30, 1900, as eight miles an hour between Newnham Ferry and Denny Farm, a river distance of about nine miles. But the velocity evidently increases as the stream narrows, and, in the short portion which we observed, it will be noticed that the velocity was more than twice that estimated over the longer distance.

CHAS. T. WHITMELL.

Leeds, February 3.

Persistence of the Direction of Hair in Man.

IN "The Descent of Man," p. 19, under the heading of Rudiments, Darwin refers to the long isolated hairs seen in the eyebrows of certain individuals, as representing similar hairs in the superciliary region of the chimpanzee, baboon and certain species of macacus. An analogous phenomenon, with a different significance, found sometimes in the pectoral region in man, seems to be worth notice. I have recently examined two persons, a male aged twenty-eight and a female aged thirty-three years, both with particularly hairless, smooth skins, and each showing, at a critical point in the pectoral region, certain outstanding hairs set closely together, the former three long hairs an inch in length, and the latter two hairs an inch and a half in length. The point of interest lies in the position and direction of these few scattered hairs, which are as noteworthy, in their way, as "erratic blocks" on a level plain. In the female case the two hairs were set just over the middle of the left second costal cartilage, and they pointed persistently *upwards* towards the neck. In the male case the three long hairs were set close to the sternum in the left second intercostal space pointing persistently *downwards*. The situations of these two curious islets of hair are exactly above, on the one hand, and below, on the other, the level at which the upward chest-stream and the downward chest-stream always divide in a hairy subject. The remarkable persistence in their ancestral direction of these few "fossil" hairs, as they might be called, seems to confirm the view that if man has inherited his hairy covering from a simian ancestry it has been modified in many regions by use and habit since he inherited it. We say that a little straw shows the way in which the wind blows, and I submit that sundry stray hairs on the body of man similarly testify as to the trend of certain mechanical forces which have acted and still act upon him.

WALTER KIDD.

The Colours of Wings of Butterflies.

MR. CROFT'S letter (NATURE, January 2, p. 198) on the subject of colours of wings of butterflies raises an interesting point.

In pressing the wings of butterflies between sheets of gummed paper in order to obtain impressions for record, I have frequently noticed that in those cases where a brilliant light blue wing is to be pressed the impression usually fails to give the correct colour; in transmitted light the impression is not blue, and in reflected light the colour is patchy and of a much darker blue; for example, the blue of a *Junonia erithyia.*

I have before me a wing—inside brilliant peacock blue, purple-blue, bronze-brown, according to the incidence of the light; in transmitted light the colour is brown. The outside of the wing is brown.

Taking an impression of this wing in transmitted light the impression is brown, in incident light very dark blue and dark bronze in patches; the peacock blue fails entirely.

If a scale of this wing be examined under a low power it appears brown in transmitted light, but peacock blue (and varying shades according to position of scale on stage with reference to light) if the transmitted light be cut off and reflected light alone used.

It would appear, therefore, that this wing owed its chief colours to other causes than pigment.

India, January 21.

EXPERIMENTS ON VENTILATING COWLS.[1]

THE report of the work of the cowl committee of the Sanitary Institute presents the results of the numerous experiments made by the committee in the course of upwards of twenty years of its existence—an existence unfortunately terminated by the deaths in rapid succession of all its members. The last survivor, Mr. Rogers Field, B.A., M.Inst.C.E, the most active member of the Committee, died on March 28, 1900.

The committee left in manuscript more or less complete records of some seven thousand experiments on cowls and terminals, together with particulars of the arrangements for testing the instruments employed, a synopsis prepared with a view to a comprehensive report, and

[1] The Work of the Cowl Committee of the Sanitary Institute. *Journal of the Sanitary Institute.* (Edward Stanford, 1901.)

some materials for a historical introduction, but practically no actual text. The council of the Sanitary Institute did me the honour of asking me to undertake the preparation of the report. For obvious reasons, the part that I could take in such an enterprise could only be a small one; it was limited to supervising the work done by two of Mr. Rogers Field's assistants and writing an occasional general note. In doing so I have regarded the report as addressed to those interested in the scientific study of pneumatics, and have not hesitated to call attention to the points in which the action of the committee seemed to me to have missed the true scientific bearings of its work. I propose to be equally frank in what I have now to say, but I would not thereby be understood as decrying the accuracy or the value of the experiments. The study of pneumatics has remained undeveloped probably more on account of the lack of accurate experiments and accurate measuring instruments than for any other reason. The records of the cowl committee bear ample testimony to the singleness of purpose of the committee in its desire to take all precautions and bring all conclusions to the test of accurate experiment, and the records of the experiments, with the limits of accuracy clearly apparent, must always be regarded as valuable data by which to test theoretical conclusions and an honourable memorial of a worthy effort to enlarge our knowledge of a most intricate subject.

The object of the committee was to compare, by direct experiment, cowls of different type as agents for producing a flow of air when exposed to wind and for preventing downdraught. The procedure adopted was to have three long vertical tubes projecting from a weather-boarded hut, erected, by permission of the Kew Observatory committee, in the Old Deer Park at Richmond. Each tube had an air meter inserted in it to measure the flow of air; the lower end was protected from draughts by a box with a silk gauze bottom; an anemometer gave the velocity of the wind, the direction of which was also recorded. The cowl was mounted on the middle of the three pipes, and the flow through that pipe was referred to the mean of the flow through the two external pipes. The tests of downdraught were of various descriptions that need not be referred to here.

With the comparison of cowls of recognised shapes there was associated an endeavour to ascertain the effect of different modifications of the orifice of a pipe, and for this purpose a number of such modifications were constructed and examined. Such modifications, some of which were very elaborate, are called terminals.

The report is divided into six parts:—

Part i. consists of extracts from introductory papers prepared by various members of the committee or from the correspondence preserved by the committee.

Part ii. contains an account of the testing of the air meters, and will be found to give a considerable amount of information of very great practical utility concerning the action of those instruments.

Part iii. gives the results of Mr. Rogers Field's investigation of the action of the anemometers employed. The instruments principally considered are a Robinson anemometer of the standard Kew pattern and a miniature instrument of the same type with one-inch cups. The chapter does not add much to the solution of the general problem of determining true wind velocity from the reading of a Robinson instrument, but it does show what kind of difficulties a careful and conscientious experimenter is likely to meet with if he sets about using such an instrument for the determination of true wind velocity. It also shows by some very useful diagrams the relation between the wind velocity and the flow up a vertical open tube over the end of which the wind passes.

Part iv. gives an examination of the degree of accuracy with which the mean of the flow in two outside pipes can be regarded as equivalent to the flow up the middle pipe. In some ways the results of this section are the least interesting of the whole number, because the observed differences which the committee attemped to resolve must be regarded as due to local circumstances which would probably not be reproduced in a repetition of the experiments under somewhat different conditions; but they are an essential part of the work of the committee; they show the limits of accuracy of the measurements under the prescribed conditions. Probably an experimenter with long experience of a laboratory might have been content to recognise after a few experiments a certain margin of experimental error as incidental to the method, and have left the cowl results with that margin of error, or have selected conditions which gave the least experimental differences; but the committee seemed unwilling to write off an experiment as subject to a certain margin of error until it had fully probed all the causes of error.

Part v. gives the results for terminals, as defined above. The results which can best be generalised are those which are represented in the report by what are known as "hill curves," by which are to be understood curves representing results obtained from a series of consecutive experiments upon terminals varying by the gradual extension of some particular dimension.

Part vi. gives the results for cowls.

A consideration of the whole report gives rise at once to curious reflections. If an apostle of higher education were looking for an example of the importance of recondite theoretical study to matters of practice, of the necessity to practical life for the academic professor in any subject, not as an exponent of the facts of the subject, but as a student and investigator of its abstract laws, he could not wish for a better example than that furnished by this report.

The original committee was appointed to settle an apparently simple practical matter, namely, which was the best among a number of cowls exhibited at Leamington in 1876 in competition for a prize or certificate. The matter was apparently confined to the region of practice, and it was at first assumed that only a few experiments were needed to settle the points in question. Experiments were made, and the committee reported to the effect that no cowl at all was as good as any; and the award went in consequence to no cowl at all. But this did not by any means satisfy all concerned, and numerous complaints were made as to the experiments and the way of conducting them.

Thereupon the Sanitary Institute appointed Sir Douglas Galton, Mr. Rogers Field and Mr. W. Eassie—the last-mentioned was subsequently succeeded by Mr. J. Wallace Peggs—to be a committee to conduct further experiments. They set out to repeat the experiments with such precautions that their results should be accepted as final. They worked with unremitting labour and at no small expense; tested to the uttermost every instrument employed in the investigation, and analysed all the conditions that might affect the results. They acted throughout upon the apparently simple practical principle that they could find out which was the best cowl if they could find out, for a certain strength of wind, which carried most air up a three-inch or a six-inch pipe, and up to what angle of tilt it could be set in various circumstances without suffering downdraught.

It certainly cannot be regarded as a fault in the committee that the subject had not been effectively worked at by some academic professor or student of experimental philosophy curious to learn, not which cowl should have a prize, but the general laws of flow of air through any cowl. They were capable, practical men, and naturally attempted a direct experimental answer. It may be true that in nine cases out of ten the best way of getting a practical answer to a scientific question is to set practical men to find it,

and that a professor of natural philosophy would spend a long time over the inquiry and return an unpractical answer. The problem attacked by the cowl committee happened to be the exceptional tenth case in which, not academic students, but practical men, spent twenty years, a period, indeed, terminated only by the deaths of the members of the committee, without arriving at practical results of the final character looked for.

As a matter of fact, the flow of air along a three-inch or six-inch tube surmounted by a cowl is a very complicated result; it is no more and no less the measure of the efficiency of the cowl on the top of the pipe than the current through a galvanometer is a measure of the efficiency of a battery cell in circuit with it. If we picture to ourselves a committee endeavouring to pronounce upon the relative merits of the battery cells of many inventors by tabulating the deflections which they produce in a galvanometer before G. S. Ohm had been led, by purely scientific researches, to the law which has been the guide in all such questions since his time, we get an exact analogy of the action of the cowl committee. Before the efficiency of the best cowl can be effectively represented by a number, it is desirable to settle what purpose the instrument is intended to serve. The production of a flow of air in a particular combination of tubes is doubtless one purpose, but there are others. Some cowls are intended to keep the rain out of a shaft; some are picturesque terminations of flues, as the Italian examples cited by Mr. Ackermann in the cowl report; all, presumably, are intended to bring profit to their makers. As regards efficiency, they might be classified according to their performance with regard to one or other of these widely different purposes, but the classification would not be strictly scientific.

To the student of theoretical science they can only be regarded as examples of apparatus for diverting the kinetic energy of the passing air to produce a flow along the pipe which the cowl surmounts, whether the flow be up or down; and the laws of transformation of the energy will most effectively describe the behaviour of the cowls from the scientific point of view. The flow along the pipe implies a certain expenditure of energy which must ultimately be derived from the passing air (in the absence of temperature difference), and the primary effect of the cowl may be estimated by the amount of energy which it takes from the wind and diverts to producing or maintaining a flow. We may call this the aëromotive force on the analogy of an electromotive force of a battery maintaining an electric flow in a circuit.

This conversion of the energy of wind into aëromotive force is in itself a very interesting subject. There is no doubt that by suitable mechanism of the windmill type (hinted at by the Archimedean screws of some revolving cowls) the wind could be made to lift through a chimney, not only air, but also, if desired, the cinders or the coals, and even the firegrate and the hearthstone itself; but the limits of effectiveness of purely pneumatic as distinguished from mechanical arrangements would be a very useful and productive subject for study. To take the matter a stage further in detail and ask whether it is possible by any combination of plane or curved surfaces to make the velocity of the air passing over the mouth of a tube greater than the original velocity of the wind, is to suggest an inquiry with important bearings upon many scientific subjects. For example, when wind blows through a truncated cone along the axis of the cone, is the velocity of emergence greater than the velocity of the unimpeded air? The cowl results do not answer this question, but indicate some suggestions. They show that a large cowl is more effective than a smaller one of similar pattern upon the same pipe; that the output of a pipe can be considerably increased by surmounting it with an extending cone-piece and adding at the widened end a "louvre" band attached by a regulated number of "feathers," and above that a cap at a certain distance. Whether this arrangement actually increases the velocity of the air passing over the mouth of a tube or merely prevents diminution only a master of theory can say. There is no experimental answer to this question.

Just as the current in a galvanometer gives no final indication of the electromotive force of a battery in its circuit, so the air current in the tube gives no final indication of the aëromotive force of the cowl. The resistances of all parts of the circuit and any accessory aëromotive forces must likewise be accounted for.

The resistances to be accounted for must refer to all parts of the complete circuit and are more complicated than electrical resistance, for they depend partly upon friction in which the loss of energy is proportional to the first power of the velocity and partly upon the turbulent motion in which the loss of energy is proportional to the square of the velocity. There are also in the circuit of flow arranged in the cowl experiments other aëromotive forces than that due to the cowl. In order to make this clear, it is sufficient to point out that the circuit consisted of the cowl, a length of three-inch pipe, an air meter, a short pipe opening into a box with a silk gauze base, and some opening, either door, or window, or chinks, between the interior of the hut where the observer was accommodated and the outside air. If the cowl had been removed the flow would not have ceased; even if the long tube were removed altogether there would be some flow through the opening, and if the opening were in the side of the hut instead of the top there would still be flow, thus indicating aëromotive forces quite apart from that due to air passing over the cowl or the top of the open tube.

The cowl committee made no inquiry into the different elements which go to make up the composite effect read on the air meter, and consequently made no attempt to analyse the effect of a cowl into the production of aëromotive force and resistance, just as the effect of a battery may be analysed into the production of electromotive force and electrical resistance. As downdraught is reversed flow, the same kind of uncertainty attaches to the results of the committee's experiments upon this branch of the subject.

The most confusing results are those for cowls used as injectors. In the case of exhaust cowls, comparison was made between the flow in three parallel pipes, the middle one carrying the cowl, the other two bare. The direction of the flow was the same in all three and all were fed from the interior of the same hut. When the effect of an injector was to be measured it was mounted upon the middle pipe, the outside pipes still remaining free. The aëromotive force in the injector pipe was, of course, reversed; one pipe supplied air to the hut and two extracted air from it. In that case flow could go on if the hut were otherwise hermetically sealed, and allowing for the hut being leaky, as it was, intentionally so, the network of currents is so complicated that it is difficult to attribute any precise meaning to the relation of the flow down the middle pipe and to that up the outside pipes, the relation selected by the committee to represent the effectiveness of the injector.

I have given some justification of the statement that the results obtained by the committee are no more indicative of the characteristic action of cowls than galvanometer readings are of the characteristics of batteries; I should like to add some words in explanation of the parallel statement that they are no less so.

If the resistances in an electric circuit are all maintained the same and the only changes introduced are successive slight modifications of the battery itself, it is quite possible to obtain from the corresponding galvanometer readings sufficiently definite information about the effect of the changes in the battery. Examples analogous to this are afforded in the report by numerous comparisons of

the effect of the different aspects of what may be called polarised cowls or terminals, *i.e.* cowls or terminals the action of which is different according to their position with regard to the direction of the wind. One of the most conspicuous is that of a cowl of the same shape as the torpedo air extractor now so much in use on railway carriages. From the numbers given, the apparatus is clearly much more effective when the wind crosses the opposed cones than when it passes along the cones and through the ring, and this difference of action is definitely characteristic of the two positions of the cowl.

Towards the end of the period of its labours the committee began to approach the question in more academic or philosophical fashion. Experiments with smoke were tried to see how cowls and terminals really acted. The committee was thus led to test the effect of successive variations of the number, size, position and arrangement of different modifying elements, such as a flange at the rim of the orifice or at a measured distance from it, a set of "feathers" arranged round the orifice and "louvre" bands or caps above it. A series of experiments to test the effect of the variation of a single element was carried out on single days and the results plotted in curves for the single varying elements. Here we have as results only galvanometer readings for different batteries, so to speak, but for batteries varying only in a single particular, and from such information effective inferences can be drawn about the action of the battery. These results afford the best material in the report for the scientific study of the action of cowls. It still remains only material, and requires working up with due regard to the theoretical considerations referred to. But some practical results follow directly. For example, a flange surrounding the orifice of the pipe diminishes the aëromotive force produced by wind passing over it, and if sufficiently extended practically annihilates the flow. It is not by any means impossible that an examination of these curves may lead to further investigation of the laws of flow through tubes under the action of passing wind. It is a subject which presents all the difficulties of the corresponding electrical problems, with some added in consequence of the inertia of the moving fluid, but it is of great practical as well as theoretical importance, and the report will have done good service if it attracts attention to the further study of the subject from this aspect.

One of the most amazing facts about the history of science in the last century is the little progress made in our knowledge of pneumatics compared with the advances in our knowledge of the flow of electricity, which still borrows its language for practical purposes from the older and now almost neglected study of the flow of fluids. The theoretical development of electricity can be attributed to Faraday's experimental investigation of the laws of electromagnetic induction. The flow of air along pipes in consequence of wind passing over the top may fairly be regarded as a case of pneumatic induction. The experiments of the cowl committee, if they have not succeeded in classifying these inductive effects into laws, have reopened the study of the subject, and at least give evidence that it is not the fulness of experimental knowledge that has dissuaded the intellects of the students of our laboratories from its investigation.

W. N. SHAW.

GOLD IN INDIA.

INDIAN gold is attracting the attention of the Geological Survey of India. In NATURE for May 9, 1901, we directed attention to Dr. F. H. Hatch's report on the Kolar gold-field in Mysore. We have now received reports on the gold-fields of Wainád, by Mr. H. H. Hayden and Dr. Hatch, and on some auriferous localities in north Coimbatore, by Mr. Hayden (*Mem.* Geol. Survey, India, vol. xxxiii. part ii, 1901.) These districts lie to the south of Mysore. The extraordinary discrepancy between reports made on various properties of Wainád by mining experts and the actual results subsequently obtained have justified independent investigations on the part of the Indian Government. It is recorded that in 1880 numerous companies, having an aggregate capital of more than four million pounds, were floated on the London market; of these only three companies retain their properties, and no work has been done for a number of years. The question to be solved was whether improved modern methods might render it possible to revive the gold-mining industry in the area. Dr. Hatch's report is, however, unfavourable. Dealing specially with two mines, he finds that ore does not occur in payable quantity, and he is unable to recommend further prospecting. Mr. Hayden gives an interesting historical sketch of the gold-mines, and describes in some detail the geological features of the district. The country-rock is in most cases biotite gneiss; this has been affected by a series of parallel fissures which run obliquely to the direction of the foliation, and in these fissures the vein-material was deposited. Pyrites proved to be the chief source of the gold, but the richer ore-bodies are small irregular patches, not of sufficient extent to be of material value.

Mr. Hayden remarks that there are few auriferous areas in India, poor as well as rich, that have not at some period or other been exploited by the natives; but the fact that gold was obtained in sufficient quantity to cover the expenses and leave a margin of profit, does not in itself justify the belief that a good margin of profit would be obtained if modern methods of working were adopted. Many of the reefs were probably mined by forced labour or by slaves. Thus one of the Wainád reefs, which was, perhaps, worked more extensively than any other, has given, from nearly 200 samples, an average yield of about two pennyweights of gold to the ton of ore. In Coimbatore there are numerous old native workings for gold, but they are, as a rule, small and unimportant, and the ore-bodies are either very thin or barren. Further prospecting, however, appears to be advisable in this district.

NOTES.

THE attendance of the Prince of Wales at the meeting of the Royal Society on Thursday last is an event which we have pleasure in recording. His Royal Highness was formally admitted as a Fellow of the Society, and remained throughout the meeting. At the close of the proceedings he was invited by the president to address the meeting, and in response he said:—"Mr. President, my lords and gentlemen,—It gives me very great pleasure to have been able to come here to-day and to be formally admitted as a Fellow of this ancient and distinguished society. But, as you conferred the honour of Fellowship upon me some eight years ago, I really ought to apologise for not having presented myself before. I can only say I am indeed proud that my name should be added to those on your illustrious roll, which has been inscribed by nearly every Sovereign since the reign of Charles II., and by all the most distinguished men of science since those days, such as Wren, Newton, Davy, Faraday, Darwin, and many others. I would wish to offer my sincere thanks to Sir William Crookes for his most interesting lecture, which I am sure we have all listened to with great pleasure. If I may be allowed to do so, I should like to congratulate him on his power of treating such an abstruse question (for I must confess that the title rather alarmed me) so as to make it intelligible and attractive to those who, like myself, unfortunately cannot lay claim to much scientific knowledge. But, while fully realising how far beyond my reach this

knowledge lies, I can assure you of my hearty sympathy with that scientific study and research, which now, more than ever, has become so important an essential in our national life."

AT the annual general meeting of the Royal Astronomical Society, to be held to-morrow, February 14, the Society's gold medal will be presented to Prof. J. C. Kapteyn, of Groningen, Holland, for his work in connection with the Cape Photographic Durchmusterung and his researches on stellar distribution and parallax. The Jackson-Gwilt (bronze) medal and gift will be presented to the Rev. Thos. D. Anderson, of Edinburgh, for his discovery of Nova Aurigæ and Nova Persei.

THE first afternoon meeting of the Chemical Society will be held on Wednesday next (February 19) at 5.30 p.m. Among the papers to be read are two on "Enzyme Action," by Prof. Adrian Brown, of Birmingham, and by Dr. Horace Brown, F.R.S., and Mr. Glendinning, and one entitled "The Union of Hydrogen and Oxygen," by Mr. H. Brereton Baker.

WE learn from *Science* that the Johns Hopkins University will celebrate its twenty-fifth anniversary on February 21 and 22, when President Remsen will be formally inaugurated. Dr. D. C. Gilman, president emeritus, will deliver a commemorative address on February 21, and President Remsen will give his inaugural address on the following day.

THE fall of red dust described by Sir Edw. Fry in last week's NATURE (p. 317) appears to have been observed over a wide area. Mr. F. H. Perry Coste sends us a cutting from the *Cornish Times* of February 8, in which it is stated that remarkable showers occurred over a large part of Cornwall during the latter part of January, the rain holding in suspension a fine dust, variously described as ranging from yellow or sandy-colour to whitish or brick-red. At Liskeard the deposit is spoken of as yellowy-red in colour; at Menheniot it had the appearance of brick-dust; at Calstock the deposit left by the rain was like fine yellow mud or sand; while, among other places in this neighbourhood, the dust attracted attention at Callington, Gunnislake and Altarnun.

THE Toronto correspondent of the *Times* writes that the Canadian Government regard with much satisfaction Mr. Marconi's recent success in signalling across the Atlantic. We rather question whether the results as yet obtained justify the hopes which seem to have been raised for a speedy establishment of cheap telegraphic communication between Canada and the mother country. More reasonable is the idea of utilising the system to its full in order to assist navigation at the mouth of the St. Lawrence. Canadian commerce, it is pointed out, will greatly depend in the future on the development of the St. Lawrence route, and there can be no question that navigation of the Gulf of St. Lawrence and the coast of Newfoundand would be much aided by a system allowing for communication between ship and ship and ship and shore.

THE Paris correspondent of the *Times* announces the death, at the age of seventy-two, of Mme. Clémence Royer, who first became known to the French reading public by her translation, in 1862, of Darwin's "Origin of Species." To this translation she prefixed what is regarded as one of the most famous essays in contemporary French thought. She was the author of "Le Bien et la Loi Morale" (1881) and of "La Constitution du Monde" (1900), and numerous original memoirs on archæology and anthropology. In 1895, MM. Berthelot, Aulard, Th. Ribot, Ch. Richet, Letourneau and Levasseur solicited for her the Cross of the Legion of Honour, alluding to her thus:—"Savante et philosophe d'une valeur rare c'est une des illustrations féminines de ce siécle." This decoration was not given her, however, until 1900, when the Minister of Education, M. Leygues, officially bestowed it at a banquet organised by Mme. Clémence Royer's Breton compatriots.

THE death is announced of Mr. William Martindale, the well-known pharmacist. From an account of his career in the *Pharmaceutical Journal* we learn that Mr. Martindale was born near Carlisle in 1840. In conjunction with Dr. W. Westcott he produced the very successful work entitled "Extra Pharmacopœia," which is highly appreciated by both physicians and pharmacists. For ten years (1873–1882) he was a member of the Pharmaceutical Society's board of examiners for England and Wales. In 1889 he became a member of the Society's council, in 1898 he was elected treasurer of the Society, and the following year he became president. He was president of the British Pharmaceutical Conference on two separate occasions; he was also a member of the council of the Royal Botanic Society, and interested himself in a scheme for the improvement of botanical teaching in London. In addition, Mr. Martindale was a Fellow of the Chemical Society, the Linnean Society, and a member of the Sanitary Institute and the Society of Arts. His position as a prominent pharmacist was recently indicated by his appointment as a member of the Privy Council's poisons committee.

A SHORT account of the results of the census of 1901 in France is given in *La Geographie* by V. Turquan. The population in each department is compared with the returns of 1801 and 1896, and the changes clearly shown by means of charts. It appears that between 1896 and 1901 twenty-eight departments show an increase averaging 25,200 each, if that of the Seine be included, or 16,000 if it be omitted, while fifty-nine departments show a decrease averaging 6000 each, a result indicating the movement of the rural population to the towns. The greatest per cent. increase is around Paris, in the departments of Nord and Pas de Calais, and along the shores of the Mediterranean; and the greatest decrease is in the basin of the Garonne, the department of Lot heading the list with a decrease of 6·1 per cent.

DR. H. FRITSCHE, director of the Pekin Observatory, has published the results of his investigation of the daily period of the elements of terrestrial magnetism, for the winter and summer seasons, based upon Gauss's general theory, and the hourly observations of twenty-seven places comprised between latitudes 80° N. and 56° S. This is the fourth work by the same author on the determination of the magnetic elements. The observations used have been collected partly from original publications and partly from those contained in the German *Meteorologische Zeitschrift*. The means are calculated from *all* the observations, including days of magnetic disturbance. Dr. Fritsche gives a detailed explanation of the formulæ employed.

THE current number of *Knowledge* contains an interesting note by Sir Samuel Wilks, F.R.S., on the history of Fahrenheit's thermometer, which, he states, owes its origin to the invention of a thermometer by Newton, described in the *Philosophical Transactions* for 1701. Newton's instrument was a tube filled with linseed oil, the starting-point being the temperature of the human body, which he called 12 (the duodecimal system being then in use); he divided the space between this and the freezing point into twelve parts, and stated that the boiling point would be about 30°. Fahrenheit, not finding the scale minute enough for his work in using Newton's instrument, first divided each degree into two parts and made it measure 24 instead of 12. Finding he could obtain a lower temperature than freezing by mixing ice and salt, he took this for his starting point, and counted 24 degrees up to body heat, making 8 freezing point and calling boiling water 53. Later on he divided each degree into four parts; it will be seen that if the last-mentioned numbers are multiplied by four, we have the thermometer which is now in use.

A YEAR ago the Scientia Club of Paris gave a dinner in honour of Prof. E. J. Marey, the eminent French physiologist, whose work has disentangled the intricacies of many animal motions. At the close of the banquet, Prof. Marey's numerous colleagues, friends and pupils expressed the desire to give tangible testimony of their admiration of his scientific achievements,

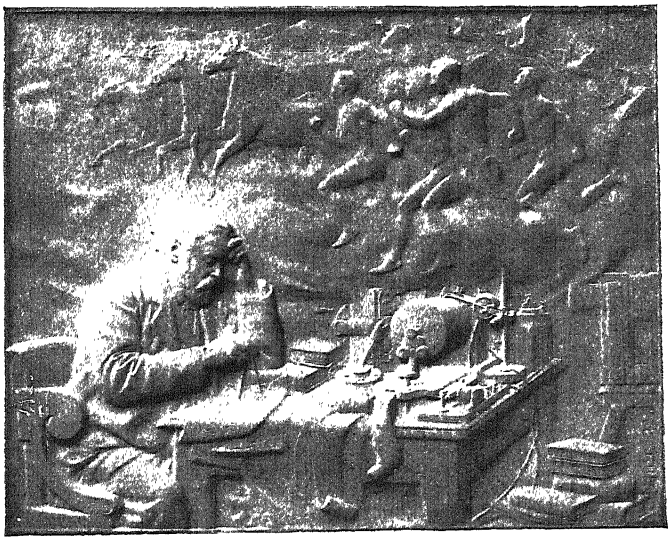

FIG. 1.—M. Marey in his laboratory. Reverse of medal.

and eventually it was decided to present him with a commemorative medal. This souvenir was engraved by Dr. Paul Richer, and the accompanying illustrations from *La Nature* show its remarkably fine character. The presentation was made to Prof. Marey at a meeting held at the Collège de France on January 19. M. Leygues, Minister of Public Instruction and Fine Arts, occupied the chair, and a large number of eminent men of science and other representatives of learning were present. M. Gaston Paris, administrator of the College, gave expression to the feelings of those who had combined to show their admiration of Prof. Marey's contributions to the study of physiological actions; and he was followed by M. Franck, one of Prof. Marey's old pupils, who described the work of his master. M. Chaveau spoke as an old and close friend, and M. Leygues, after referring to the chief characteristics of Prof. Marey's researches, remarked in conclusion:—"Je prie Monsieur Marey, au nom du gouvernement de la République, dont je suis ici le représentant, d'agréer l'hommage de sa reconnaissance et de sa respectueuse admiration." Letters and telegrams of congratulation were received from many physiologists unable to be present at the meeting; and Prof. Marey replied in appropriate terms of thanks to the numerous expressions of regard of which the medal which has been presented to him is a token.

REFERRING to the experiment described by Mr. F. Hodson in last week's NATURE (p. 319), Mr. J. D. T. Morris writes from the East London Technical College to say that it is possible to produce both kinds of electrification in sealing-wax by rubbing it with silk. As with the glass rubbed with fur, gentle rubbing produces positive electrification and more vigorous rubbing produces negative electrification. The change is probably due to difference of temperature of the surface of the material used, caused by the varying amount of energy used in the friction.

A NEW monthly journal has just been started at Florence, bearing the title *La nuova Rassegna tecnica internazionale*. It contains abstracts of important papers on engineering and applied science, a summary of current literature in this region, both Italian and foreign, notices of books, of exhibitions, prizes, vacant appointments and congresses. In the present number, projected railways and automobiles receive a fair share of attention. The *Rassegna* should be useful in giving a synopsis of the most important topics of the day in connection with practical engineering.

SOME interesting details relative to trials with secondary batteries for electric traction on branch lines of railway in Germany are given in the issue of the *Centralblatt für Accumulatoren- und Elementenkunde* for December 15, 1901. These trials were instituted in 1898, after a special form of Planté cell had been devised for the particular work. The negative plates of the cells were found in actual use to have a shorter life than the positive plates, and it was necessary to take these out and to repaste them after they had done duty for 30,000–40,000 km. The batteries were carried under the seats of the carriages, and weighed fifteen tons; while the complete weight of a carriage, with its motor equipment and complement of 112 passengers, was fifty-three tons. Two of these larger carriages and two smaller ones, with accommodation for sixty-eight passengers, were built, and were regularly run on branch lines connecting the following towns in the Palatinate:—Ludwigshafen Neustadt, Worms, Schifferstadt, Landau and Amweiler. The normal speed at which these carriages were run was one of 45 km. per hour. The total cost of the larger carriages was 2750*l*., the electrical equipment representing 1625*l*. of this total. The running costs are stated to have been 27·5 pfg. per car kilo-

FIG. 2.—M. Marey, Member of the Institute of France. Face of medal.

metre when generating charges were included, and only 21 pfg. when the batteries were charged at the central lighting station—presumably in Ludwigshafen. The corresponding charge for

steam traction is stated to be 28 pfg. In the light of these trials the use of accumulator traction on short branch lines of railway, is considered to be practicable and economical.

Prof. Holborn, of the Reichsanstalt, Berlin, has designed a new form of electric resistance laboratory furnace, which permits temperatures up to 1500° C. to be attained with ease by use of the ordinary 110-volt electric supply. These furnaces are made in two forms, the first being adapted for heating crucibles and the second for heating tubes 44 cm. in length. Both forms of furnace are alike in principle, the electric current being conducted through a resistance coil of platinum or nickel wire, wound round a thin porcelain tube or cylinder. The crucible or substance to be heated is placed within this latter, and the space between the outer side of the coil and the containing vessel is packed with asbestos or powdered quartz. Using nickel, the temperature of the furnace cannot be raised above 1000° C. without damage to the coil, but with platinum it is possible to attain a temperature of 1500° C. with a current of 14 amperes and 110 volts. It is necessary in the use of these furnaces to include a resistance in the circuit and to use only one-half of the maximum current when the heating is first commenced. The use of exterior resistance enables the temperature of the furnace to be regulated with ease, within somewhat narrow limits. Further advantages claimed for these furnaces are—that the separate portions are replaceable when worn out, that the heating spirals can be easily removed and changed to suit the special temperatures required, and that with the tube form of furnace, the heating of the substance can be carried on in the absence of air and in the presence of any desired gas or gaseous mixture. It would be interesting to know whether any attempts have been made to apply electrical resistance heating, to organic combustion work. The usual type of gas-heated combustion furnace is capable of improvement, and the substitution of electricity for gas would bring with it some notable advantages. In localities where the day supply of electricity is at reduced rates, this application is worthy of attention.

The climate and artesian waters of Australia form the subject of an essay by Mr. J. P. Thomson (Queensland *Geographical Journal*, vol. xvii. No. 2, 1902). The author maintains that the great central basin of Australia, as well as certain valleys within the area, are hemmed in by ancient crystalline, Palæozoic and Mesozoic rocks of an impervious character; and that during the Cretaceous period the valleys were filled up and the level of the central basin raised by detritus from the adjacent mountain ranges. Thus extensive beds of sand and gravel were spread out, and these were followed by a deposition over the central area of fine clays and shales. The clays to a certain extent seal up the water which is held in the Cretaceous sands and gravels, and thereby a good source of artesian water is provided. Since his paper was printed, Mr. Thomson announces (*Brisbane Telegraph*, December 28, 1901) that the existence of an abundant supply of good drinking water has been proved at a depth of 30 feet in the Eucla district north of the Great Australian Bight. This discovery indicates that inland settlements may be feasible in tracts which furnish good indigenous bush feed for cattle, but have hitherto been regarded as drought-stricken.

We have received a copy of a paper by Mr. P. Frandsen, published in the *Proceedings* of the American Academy (vol. xxxvii. No. 8), on the effects of directive stimuli on slugs. It appears that, as the result of previous experiments, it has been stated that when slugs are placed on an inclined plane of glass, some move in an upward and others in a downward direction. One of the objects of the author's investigations was to test the truth of this statement, and, if true, to find a reason for the diversity of habit.

In his presidential address to the Edinburgh Field Naturalists' and Microscopical Society, which appears in the *Transactions* for 1901, Mr. W. C. Crawford gives an interesting account of the ant-colonies shown in the Paris Exhibition, and suggests that similar exhibits might with advantage be introduced into this country. In the same volume, Mr. T. Speedy gives some interesting notes on the life-history of the badger, while Mr. A. A. Pinkerton discourses on the habits of the mole. In the course of his paper the former gentleman states that it is a common belief that young badgers do not suckle till a considerable time after birth.

Special interest is attached to Mr. R. Quick's paper on "Human Bone Instruments" in *The Reliquary and Illustrated Archaeologist* (vol. viii. January, 1902, p. 28), as the figures which illustrate it are from specimens in the Horniman Museum. It will be in the memory of our readers that this really remarkable museum was given last year by Mr. Frederick John Horniman, M.P., to the London County Council to be freely open to the public. In Mr. Quick's somewhat discursive paper an interesting series of three Tibetan drums is figured; the first is made of two human calvaria fastened back to back so as to form a sort of hourglass-shaped instrument, two knotted strings constituting the clappers. Another specimen is a brass model of two calvaria, and the third is a wooden one yet more conventionalised. Trumpets made from the thighbones of lamas and a lama's skull cap used as a drinking vessel are also illustrated.

A good deal of untrustworthy theorising has been applied to textile markings found on the pottery of primitive peoples; Mr. W. H. Holmes has a careful, discriminating paper on this subject in the *American Anthropologist* (iii. 1901, p. 397). He finds pottery so marked can be divided into five classes: (1) Impressions from the surface of rigid forms, such as baskets; (2) Impressions of fabrics of a pliable nature, such as cloths and nets; (3) Impressions from woven textures used over the hand or over some suitable modelling implement; (4) Impressions of cords wrapped about modelling paddles or rocking tools; (5) Impressions of bits of cords or other textile units, singly or in groups, applied for ornament only and so arranged as to give textile ike patterns. In addition we have a large class of impressions and markings in which textile effects are mechanically imitated. Those who are interested in our own prehistoric pottery should study Mr. Holmes' paper.

A new volume of *The Geographical Journal*, containing the numbers published in the latter half of last year, has been received. Among the papers in the volume we notice the following as of wide interest:—Sand-waves in tidal currents, by Dr. Vaughan Cornish; the Antarctic voyage of the *Belgica* during the years 1897, 1898 and 1899, by Mr. H. Arçtowski; the anthropogeography of Argentina, by Dr. F. P. Moreno; the National Antarctic Expedition; and the lake-level of the Victoria Nyanza, by Mr. E. G. Ravenstein. There are in addition a number of papers on explorations, accompanied by maps, and the usual monthly record of progress in the knowledge of geography.

Messrs. Sanders and Crowhurst have sent us for examination a number of brilliant lantern slides of birds and other zoological subjects. Photography has been a helpful handmaid to many branches of science, but none of its performances are more widely appreciated than those in the field of natural history. Drawings of animals may have artistic merit, but they do not inspire the feeling of life which is conveyed by good

photographs of objects in their natural surroundings. The lantern slides sent by Messrs. Sanders and Crowhurst are from photographs of birds, nests, eggs and young and other living animals taken by Mr. Oliver G. Pike. To lecturers on natural history such true pictures of living creatures must be invaluable, and no better source of encouragement to study nature could be desired. By the side of such beautiful photographic pictures as are now available for projection upon a screen or for the illustration of books, the drawings which did duty in natural history instruction seem but a vain show. Messrs. Sanders and Crowhurst send us with their slides an ingenious arrangement for viewing lantern slides under a low magnifying power. The arrangement, though simple, is very effective, and a pleasant half hour can be passed by using it to look at lantern slides.

THE additions to the Zoological Society's Gardens during the past week include a Greater Vasa Parrot (*Coracopsis vasa*) from Madagascar, presented by Lady Amherst of Hackney; a Black-footed Penguin (*Spheniscus demersus*) from South Africa, presented by Lieut. F. J. Mosely; a Black-headed Gull (*Larus ridibundus*), European, presented by Miss M. Hall; a Bataleur Eagle (*Helotarsus ecaudatus*) from Lagos, presented by Mr. J. Peacock; two Yellow-cheeked Amazons (*Chrysotis autumnalis*) from Honduras, two Wall Creepers (*Tichodromus muraria*), European, deposited.

OUR ASTRONOMICAL COLUMN.

DISTURBANCE OF CORONA IN NEIGHBOURHOOD of PROMINENCES.—Prof. C. D. Perrine, who had charge of the expedition to Sumatra organised by the staff of the Lick Observatory to observe the total eclipse of the sun on May 18, 1901, gives in his report a preliminary description of the results obtained in the *Astrophysical Journal*, vol. xiv. pp. 349-359. From a short examination of the photographs of the corona obtained with the forty-foot and Floyd telescopes (which are stated to show the details of the inner corona very perfectly in spite of the presence of clouds during the exposure), there is distinct evidence of disturbances in certain areas of the coronal structure. Especially noticeable is a conspicuous series of coronal hoods surrounding a prominence in position angle 115°, and also an unusual appearance in the north-east quadrant of the corona. This latter is near position angle 65°. Close to this point on the limb there is a small compact prominence, surrounding which the disturbed area has a form roughly resembling an inverted cone of large angle. The apex of this area is not visible, appearing to lie below the chromospheric layer showing at the limb. From the apparent position of the apex, a number of irregular streamers and masses of matter radiate as if propelled by some explosive force. A long thread-like prominence to the south of this point appears to originate from the same source. Above and around this region the corona is composed of broken irregular masses, very similar to those depicted on the photographs of the Orion and other nebulæ.

A NEW SOLAR THEORY.[1]

IT is a remarkable fact that in the numerous theories which have been propounded in explanation of the periodic changes of the solar phenomena no account has yet been taken of so important an element as the light- and heat-absorbing envelope surrounding the photosphere. The attention which this so-called solar atmosphere has hitherto received, on the part even of our most eminent investigators, in connection with the economy of radiant energy on our luminary, is utterly disproportionate to the importance of the subject. In spite of the fact, which was first accurately established by Langley's observations and was afterwards confirmed by others, that the sun, if deprived suddenly of this protecting screen, would radiate into space as much as double its present amount of energy, solar physicists failed to perceive that changes in the absorptive power of this envelope must entail consequences of the most far-reaching character with respect to the thermal conditions on and in the sun. That such changes—and these, too, of no inconsiderable magnitude—must inevitably occur is a conclusion which it is hardly possible to evade when it is remembered that the supreme control over the dispensation of solar energy depends entirely on a thin, shallow surface-layer, the matter of which is constantly tossed about by vehement eruptions and acted upon by a most complicated and powerful system of convection currents to and from the sun's centre.

The possibility of variations of the opacity of the solar atmosphere was, it is true, strongly urged, more than twenty years ago, by one of the greatest authorities on this question. Shortly after his well-known researches into the absorbing faculty of the solar envelope, Langley pointed out the decisive influence on the sun's radiation into space caused by changes in the transmissive power of its atmosphere. But his attention was at the time solely directed towards their probable effects on the temperature of our own planet. He found that an increase of absorption by as much as 25 per cent. would diminish the mean surface temperature of our globe by 100° F., whilst a like diminution in the solar envelope would produce a corresponding change in the opposite direction.

Now if the influence of a change in the absorptive power of the solar atmosphere is so enormous on a planet at a distance of almost a hundred millions of miles, of what inconceivable importance must it not be for the sun itself? Drawing the very natural inference that a *deficit* of outside radiation means a *surplus* of energies working upon the solar matter, and *vice versâ*, we are forcibly led to conclude that even slight changes of opacity, such as would elude our most refined observations, are bound to greatly influence the state of thermal equilibrium on our luminary.

Hence, if changes in the absorptive power of the sun's atmosphere exist, as cannot but be the case, the question presents itself: What happens with those energies which, by a condensation of the solar envelope, are prevented from escaping into space? No doubt they are preserved to the sun, but in what form? Do they raise the temperature of the solar mass, or augment its store of potential energy, or have they a share in the generation of those marvellous dynamical displays which we perceive in periodic succession on the solar surface? Questions such as these must tend to convince the investigator that a research into the causes of the variability of the forces which we see acting on the sun, if not identical with, is at least closely akin to, the investigation of the origin and the physical properties of the sun's atmosphere. I shall endeavour, in these columns, to demonstrate the possibility of such changes in the density of the solar envelope as would lead to alterations of the thermal conditions of the sun's mass, and shall make an attempt to answer the question as to how far these changes must be conducive to variations in the dynamical phenomena at the sun's surface.

There is perfect unanimity amongst astronomers as regards the nature of the force which by a continuous generation of heat compensates for the loss of energy into space. Helmholtz's theory, which attributes this heat-generation to the progressive contraction of the solar mass as a consequence of gravitation, may be regarded as one of the most probable hypotheses ever propounded in the history of physical science. But this theory does not yet enable us to form an idea of the evolution of a celestial body. It explains the existence of a heat-generating force within the star's bulk, but it gives no answer to the question as to whether the loss of energy by radiation is exactly compensated for by the generation of energy through contraction, or whether the conditions of contraction peculiar to the sun may not perhaps produce *more* or *less* heat than is required for compensation. It is, indeed, inconceivable that the conditions of contraction can remain the same throughout the lifetime of a star. The spectroscope has revealed the fact that the photospheres of different stars exhibit widely different stages as regards temperature. There are doubtless suns hotter than ours, and others considerably cooler. And we may confidently assume that the various conditions of temperature now recognised in the different types of star-spectra represent the phases which successively appear in the evolution of each of these bodies from its origin as a far-extended nebula down to its complete obscuration. In the life of each of these stars there will be a period when its temperature is on the ascent, and when, consequently,

[1] Abstract of a paper in *Astr. Nachr.* (No. 3723-24): "Ueber eine neue Theorie zur Erklärung der Periodicität der solaren Erscheinungen."

the heat-generating effect of the contractile force exceeds the loss by outward radiation, as well as another period when the declining temperature of the star indicates an excess of the heat-dissipating over the heat-producing forces. Which of these conditions, at the present moment, prevails on our sun can so far be only a matter of conjecture. In this respect, therefore, an assumption has to be made. The following inquiry applies to the case of a star on which the generation of energy by contraction falls short of the loss of energy by radiation. Whether the results of this investigation may be applied to the case of our sun must, then, depend on the further question whether the sun really belongs to those stars the temperature of which is declining. So far as I know, this latter opinion is at present held by the great majority of astrophysicists.

If on a star the loss of energy exceeds the production, the kinetic energy of its molecules, and consequently its absolute temperature, must decrease. Hence if the temperature of a layer, a_n, at a certain distance, ρ_n, from the centre was T_1 at the epoch t_1, it will be T_2 at a later epoch t_2, where $T_2 < T_1$. Now let a_1 be the level of the photosphere—or the level of maximum incandescence, and therefore also of maximum radiation—at the epoch t_1. In consequence of deficient contraction the temperature of this layer must decrease, and the materials composing it must cool down, so that, at the subsequent epoch t_2, the level of maximum incandescence will have shifted towards a layer, a_2, nearer to the star's centre, where the temperature is still sufficiently high to maintain the incandescent state of all the particles. The space between a_1 and a_2 will then be occupied by particles in a less luminous state which act as an absorbing screen on the radiation emanating from a_2. Whatever fraction of the total radiation which originally left the photosphere at a_2 is thus stopped in its outward progress will be in part absorbed by, and in part reflected from, the intervening particles of the layer a_1a_2, and there can be no doubt that some at least of this arrested energy will ultimately be thrown back to a_2 from which it started. The layer a_1a_2 must therefore act on the photospheric radiation in the same way as do our atmosphere and its clouds on the radiation from the soil. We are quite familiar with the fact that clear nights are, as a rule, cooler than cloudy ones, and we explain this phenomenon by the assumption that on clear nights radiation from the soil into space goes on more freely than when clouds offer an effective impediment to the dissipation of radiant energy.

We conclude, then, that the progressive cooling of the star leads to the formation of an absorbing envelope above its photosphere, by which the disproportion between the generation and loss of energy is reduced. But if, under the conditions at the epoch t_2, the amount of energy actually radiated into space still exceeds what is produced by contraction, the photosphere will move to a_3, still nearer to the centre, and the quantity of absorbing matter in the layer a_1a_3 will be further increased. Now although a_3 emits the same quantity of energy as did a_2 and a_1 at the former epochs, the total amount of radiation emerging into space must, at the epoch t_3, be less than it was at t_2 and t_1. Thus the opacity of the cooled atmosphere gradually increases as time goes on, and the total radiation of the star becomes less and less. Since no force is present to interfere with the cooling of the layers $a_1, a_2 \ldots$, a moment t_n must eventually be reached at which the photosphere at a_n, through reflection from all the layers above it, receives back so much of its radiation that its total expenditure of energy is exactly counterbalanced by the energy contributed by the contractile forces.

This result appears to be of eminent importance. For it shows that even on a star with deficient contraction the *exact* compensation of the loss of energy may still be possible from a certain layer downwards. This state, so exceedingly important for the conservation of energy within the star, is brought about by the progressive cooling of its superficial layers, which thereby increase their power of absorption and thus offer a more and more effective check to the radiation from the incandescent layers below.

Here, now, we are confronted with a question which leads us at once to the principal object of this inquiry: Can the state of thermal equilibrium thus eventually attained by the layer a_n be permanent? The answer is clearly negative. For when a_n has arrived at this state, none of the layers $a_1, a_2 \ldots a_{n-1}$ outside a_n have reached the same condition. Their cooling is bound to go on, and consequently their ability to absorb and reflect the heat emanating from the layer a_n must still further increase even after the establishment of thermal equilibrium at a_n. But, owing to this increasing amount of reflection towards it, the layer a_n will now dissipate even *less* energy than is required for the maintenance of thermal equilibrium, and therefore must become *overheated*. It thus comes to pass that, while the function of the absorbing envelope is that of reducing as much as possible the waste of energy from the photospheric layers, it is, by the very nature of this process, compelled to *overdo* its work, and to preserve finally too much energy within the star.

Now by this gradual overheating of the inner layers the vertical temperature-gradient must increase more and more, until it reaches a degree of steepness at which the permanence of a mechanical equilibrium becomes impossible. In such a case the overheated gaseous matter will force its way outwards and will break through the "cloak" of absorbing elements above it. But the overheated matter will not at once obey its molecular impulse to escape into higher levels. We must remember that there exists a powerful system of convection currents between the interior and the surface of the sun, and that the overheated particles may for some time be swept along the paths of these currents and may thus be forcibly detained in levels inconsistent with their increased temperature, so that their state of equilibrium is rendered unstable. This will produce a tension which increases in course of time until the upward tendency of the overheated particles becomes strong enough to overcome the resistance of the currents. At such a critical moment even a slight disturbance will be sufficient to induce the upward motion so long restrained, thus giving rise to a solar eruption. The cause of a solar outburst is therefore to be found in the temporary existence of an excessively great vertical temperature-gradient caused by progressive cooling of the outer atmospheric layers and the ensuing overheating of the inner photospheric layers.

From this exceedingly simple principle we are able to deduce an analytical demonstration of the periodicity of solar phenomena which explains all the characteristics of the sunspot curve hitherto observed. Obviously, the problem consists in demonstrating the changes in the amount of outward radiation which are caused, on the one hand, by the increase of absorptive power of the atmosphere in consequence of its progressive cooling, and, on the other, by the reduction of absorptive power of this same atmosphere in consequence of the "clarifying" action of eruptions which, by breaking through the "veil," diminish the number of cooled absorbing elements at the localities of eruption. I shall not enter upon this part of my investigation in the present note beyond stating that it is a simple application of Bouguer-Lambert's formula for the extinction of light and heat in an absorbing medium. The energy ϑ of the radiation leaving the upper limit of the atmosphere is found by the differential equation

$$\frac{d^2\vartheta}{dt^2} + a\frac{d\vartheta}{dt} - a\beta\vartheta = o,$$

where t denotes the time reckoned from the moment when the photospheric layer a_n has attained its state of thermal equilibrium, and a and β represent constants, the former of which depends on the rate of cooling of the atmosphere, the latter on the action of the eruptions. The integral of this equation will thus give us the changes in the radiating power of the sun towards a point in the universe. Considering that the intensity of the dynamical phenomena at the solar surface must depend on the excess of energy preserved to the sun beyond what he requires for the maintenance of thermal equilibrium at a_n, we arrive at the following theoretical equation for the frequency of eruptions and spots:—

$$r = a\left[1 - e^{\lambda_1 t} + \frac{e^{\lambda_1 p} - 1}{1 - e^{\lambda_2 p}}\left(1 - e^{\lambda_2 t}\right)\right]$$

where p is the period and

$$\lambda_1 = -\tfrac{1}{2}a + \sqrt{\tfrac{1}{4}a^2 + a\beta}$$
$$\lambda_2 = -\tfrac{1}{2}a - \sqrt{\tfrac{1}{4}a^2 + a\beta}.$$

It is readily seen that r starts from zero at the moment $t = o$, and that it reverts to zero at the moment $t = p$. Between these two moments r attains a maximum, and we find the time when this occurs from the equation

$$e^{(\lambda_1 - \lambda_2)t_m} = \frac{\lambda_2}{\lambda_1}\frac{1 - e^{\lambda_1 p}}{1 - e^{\lambda_2 p}}.$$

Now it can be shown that the right-hand side of this equation is under all conditions $< e^{(\lambda_1-\lambda_2)\frac{p}{2}}$, and this the more so the greater the difference between λ_1^2 and λ_2^2. Hence we deduce $t_m < \frac{1}{2}p$; *i.e.* the ascent from zero to the maximum must take place in an interval of time shorter than half the period. This constitutes the first theoretical proof of the well-known property of the observed spot-curve that the ascent is steeper than the descent.

To give some idea of the accuracy with which the above theory can be made to represent the observed facts, I subjoin a plate (Fig. 1) in which the spot-curve, resulting from theoretical considerations, is compared with Spörer's curve derived from observation. A full description of the method by which the theoretical curve has been obtained will be given in a paper shortly to be published as part of the first volume of the *Annals* of the Royal Observatory, Edinburgh.

The theory also accounts satisfactorily for the existence of a "great" period of solar phenomena. This greater cycle is brought about by the influence of the surface fluctuations of temperature described above on the intensity of the convection currents which regulate the interchange of heat between the interior and the surface. It is inconceivable that in a gaseous body like the sun, governed by a gigantic convection, changes of temperature of parts of its mass can be confined merely to the surface. Hence we must conclude that the distribution of temperature throughout a considerable part of the sun's bulk will be more or less affected by the fluctuations of temperature at the surface, and that consequently the intensity of the system of convection-currents, which depend on this distribution of temperature, must undergo variations similar to those exhibited by the dynamical phenomena at the surface. Now these variations must react on the development of eruptions and spots. If the currents are weak—viz. if the transfer of heat from the interior to the surface is comparatively small—the cooling of the atmosphere must proceed rapidly, and hence the development of eruptions, which are a direct consequence of this process of cooling, must be energetic. At such times we have, therefore, to expect solar cycles with a powerful display of dynamical phenomena. If, on the other hand, the currents are intense—viz. if the heat-supply from the interior is vigorous—the rate of atmospheric cooling will be small, and we have then to expect cycles with only a weak development of surface phenomena.

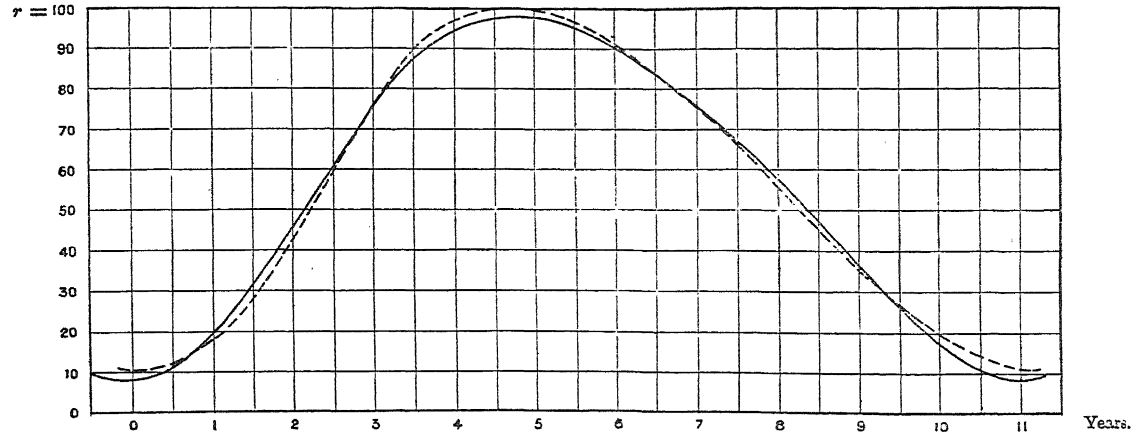

FIG. 1.——Theoretical curve of solar spots. . . . . . Observed curve of solar spots (Spörer).

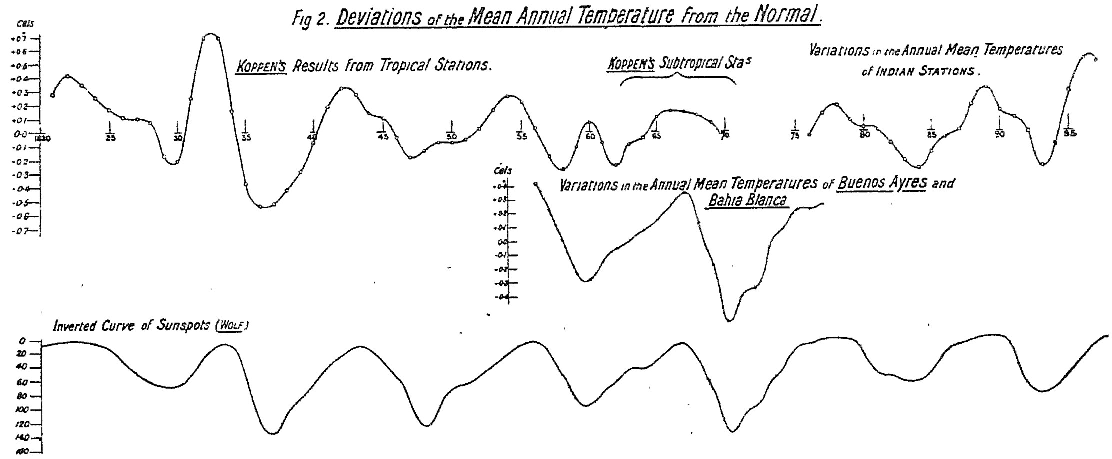
Since the quantity α depends on the rate of cooling of the atmospheric layers, it will attain high values at times when the spot-development is powerful, and *vice versâ*. Now the greater α, the greater will be the difference between λ_1^2 and λ_2^2, and, consequently, the earlier must the time of maximum, t_m, occur. Hence the position of the maximum in the spot period relatively to the preceding minimum must depend on the greater or less vigour of spot-development during the cycle, inasmuch as the time of maximum must be the more in advance of the centre of the period the greater the display of the dynamical phenomena. This important conclusion, arrived at by purely theoretical considerations, is amply corroborated by the facts. I refer in this respect to a recent publication of Dr. W. Lockyer, in which this peculiar shift of the maximum is pointed out as a feature of the observed spot-curves.

Fig 2. Deviations of the Mean Annual Temperature from the Normal.



The object of this brief abstract being merely an exposition of the main principles upon which I have ventured to build a new solar theory, I shall not enter upon its various applications to the phenomena connected with the periodic changes in the

display of forces at the sun's surface. In this respect the theory will be submitted to an exhaustive test in my paper in the *Annals*. In one important point it involves a radical deviation from the views hitherto held. So far investigators have almost unanimously adhered to the traditional view that an increase in the dynamical forces at the sun's surface indicates at the same time an augmentation of his light- and heat-radiation into the universe. A theory founded on this assumption would have to account, not only for the extra expenditure of force into space, but also for the simultaneous increased development of force in the sun. But in the theory here proposed the exactly opposite conclusion is arrived at. Here the forces which we see acting on the sun are called into existence by the accumulation of such parts of his radiating energy as have been *prevented* from being thrown off into the universe. Thus a *surplus* of energy working on the sun means a *deficit* of energy communicated to space.

It will be important, then, to ascertain how far this conclusion can be verified by observed facts. Modern researches seem, indeed, to corroborate this theoretical result. If the theory be true, the temperature of the solar layers inside the absorbing atmosphere should be higher at the maxima than at the minima of solar activity, while the temperature of a body in space, which receives its heat from the sun, should vary inversely. In proof of the first conclusion I may refer to Sir Norman Lockyer's results with regard to the behaviour of the lines widened in the spectra of sunspots, from which he infers that the matter composing the spots must be of higher temperature at the times of maxima. The second conclusion, on the other hand, is corroborated by all the more important researches which have recently been made regarding a connection between the changes of terrestrial temperature and solar activity. Of some of these I subjoin the main results in Fig. 2, which exhibits the observed changes in the mean annual temperature at tropical and subtropical stations and the corresponding variations of solar activity. It will be seen that for the whole period from 1821 until 1898 the temperature-curve follows most accurately the fluctuations of the *inverted* spot-curve, thus so far proving the validity of the second conclusion, that space receives *less* heat at the maxima than at the minima of solar activity.

J. HALM.

MICROSCOPICAL EXAMINATION OF ALLOYS OF COPPER AND TIN.[1]

THE microstructure of the copper-tin alloys has been studied by Behrens, Charpy, Stead and others. Recently Messrs. Heycock and Neville (*Phil. Trans.* Royal Society, 1901; Glasgow meeting, British Association) have published several papers on the effect of quenching upon the microstructure. Behrens divides the bronzes into two principal groups—those rich in copper, containing from 1 to 25 per cent. of tin, and those rich in tin, containing more than 25 per cent. of tin. With the exception of the metals for mirrors (25 to 35 per cent. of tin), which appear homogeneous, Mr. Behrens says that in all bronzes a portion rich in copper or rich in tin may be detected, forming the fundamental mass, the former in alloys rich in copper, the latter in those rich in tin.

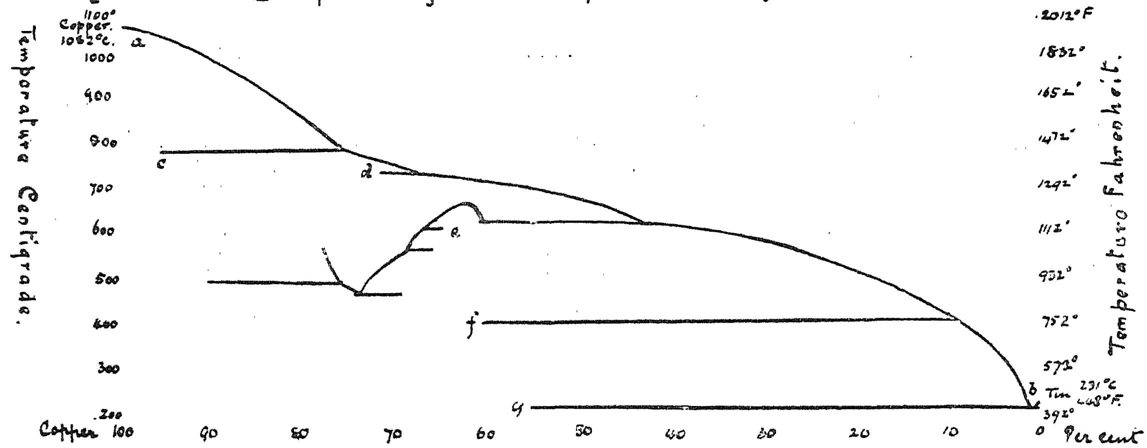
Charpy (*Metallographist*, vol. i. p. 193) divides them into those rich in copper, containing 100 to 73 per cent. of copper, and those rich in tin, which are again divided into four groups—0 to 3 per cent. of copper, in which tin crystallises in the matrix; 3 to 55 per cent. of copper, in which a compound of tin and copper crystallises out of the matrix; 55 to 65 per cent. of copper, which have a structure quite homogeneous and difficult to resolve; and 65 to 73 per cent. of copper, in which hard white grains crystallise in the higher eutectic.

The curve of fusibility, as determined by Le Chatelier, is composed of three branches, forming by their intersections two points corresponding to alloys with 3 and 72 per cent. of copper.

0 to 3 per cent. of copper:	straight:	fall.
3 to 72 ,, ,,	uniformly curved:	rise.
72 to 100 ,, ,,	almost straight:	rise.

This curve and the results of Charpy (*Bull.* Soc. d'Encouragement, March, 1897) from microscopic analysis closely agree.

Fig 1. Freezing-point Curve of Copper-Tin Alloys.
IV. Report Alloys Research Committee.



If, however, we study the complete cooling curve of th copper-tin alloys, by Sir William Roberts-Austen (Fig. 1), th meaning of only a part of the curve will be found to have been explained by previous workers. The branches *c*, *d*, *e* and *f* remain unaccounted for.

The result of the microscopical study of these alloys is shortly as follows:—

0 *to* 1 *per cent. Copper.*—On the addition of even 0·1 per cent. of copper to tin, a new constituent surrounding the grains of tin can be seen. As the percentage of copper increases, the amount of enveloping material increases also, and the tin grains decrease in size and number until about 1 per cent. copper; they entirely disappear when the whole mass is composed of the first eutectic alloy. When these alloys are cast, the grains of tin are greatly reduced in size.

1 *to* 8 *per cent. Copper.*—When the copper is increased above 1 per cent., thin bright needles are seen, which increase in size and number and vary in their method of grouping until 8 per cent. of copper is reached. Their composition varies also, increasing from 33·5 per cent. Cu to 44 per cent. Cu, as was pointed out by Stead (*Journal* of the Society of Chemical Industry, June, 1897). Casting produces a network of fine crystallites, which tend to set along definite directions forming skeleton crystals. Cooling in the furnace greatly increases the size of the bright crystals and diminishes their number proportionately.

9 to 40 *per cent. Copper.*—With 9 per cent. Cu a new constituent crystallises out in forms similar in section to the crystals

[1] Abstract of a paper by Mr. William Campbell, Columbia University, New York, late of the Royal School of Mines, London. Read before the Institution of Mechanical Engineers on December 20, 1901.

in the 1 to 8 per cent. alloys, but differing from them in never occurring hollow. On oxidation it becomes very dark and is easily distinguished from the other two constituents of the alloy. In form it is plate-like, and around it crystallises out the bright constituent characteristic of the 1 to 8 per cent. alloys, either as a rough envelope of fairly uniform thickness or as projecting crystals. Stead was the first to draw attention to the fact that the crystals of this division of the series were composite. As the copper approaches 40 per cent., the plate-like crystals are grouped together in parallel bunches. Casting masks the composite character of the crystals, if, in the lower percentages, it does not destroy it; for under 20 per cent. Cu, the crystals cannot be resolved into two components under high powers.

41 *to* 61·7 *per cent. Copper.*—At 41 per cent. Cu the crystals are small, lath-shaped, and arranged more or less in groups. The alloy is brittle, and this brittleness increases with the percentage of copper. With each addition of copper, the groups of composite crystals become more and more compact and the amount of eutectic diminishes until at 56 per cent. Cu it disappears (Stead, *Journal* of the Society of Chemical Industry, June, 1897), and the bright constituent of the crystals forms the groundmass. When 61·7 per cent. Cu is reached, the bright constituent disappears and we have a homogeneous mass of $SnCu_3$, probably a definite compound. Casting tends to harden and toughen these alloys. Seeing that these alloys up to about 56 per cent. Cu show four breaks in their cooling curves, one would naturally expect to find four different constituents in each. Only three, however, can be distinguished. Quenching below the first and second breaks gives a difference in structure only. As in the alloys containing 61·7 per cent. Cu and onwards, branch *e* of the curve (Fig. 1) corresponds to a rearrangement in the solid, and as the difference between the 40 and 41 per cent. Cu alloys is one of structure only, we may assume that the second retardation in the cooling curve (*e*) is one of rearrangement also.

61·7 *to* 68·28 *per cent. Copper,* $SnCu_3$ *to* $SnCu_4$.—The changes which take place between these two points can only be observed when the alloys are very slowly cooled. The alloys set as a whole at the first break and tend to rearrange themselves subsequently in the solid, on branch *e* (Fig. 1). Each addition of copper to $SnCu_3$ brings in more and more of a bright constituent, probably $SnCu_4$. Quenching and casting produces structures entirely new. Figs. 2–5 show the 66 per cent. Cu alloy differently cooled. Fig. 2 was quenched on the first break. There is a cell-like structure with light-coloured walls or boundaries. In places the change has gone further, and we get the fine cross-hatching characteristic of Fig. 3, which has been quenched below the first break. The cell-like structure has entirely disappeared. Fig. 4 has been quenched below the second break and resembles a slowly-cooled alloy, except that in the latter there are distinct traces of a eutectic structure. Fig. 5 has been cast on an iron plate, and the "schiller" structure is well developed. At 68·2 per cent. Cu the alloy is homogeneous, has a conchoidal fracture and is extremely brittle.

68·28 *to* 75 *per cent. Copper.*—Immediately the copper is increased above 68·3 per cent., the second eutectic makes its appearance. As the copper increases, the grains of $SnCu_4$ split up into bright veins and dendrites, surrounded by the eutectic. The veins and dendrites decrease and disappear at 75 per cent. Cu, where the mass is made up entirely of the eutectic. The alloys are best studied when furnace-cooled; their surfaces above 71 per cent. Cu are seen to consist of a network of dendrites or skeleton crystals resembling those seen on the surface of a pure metal. This surface structure continues right up to the copper end of the series. It was soon noticed that the internal structure of the alloys from 70 to 75 per cent. Cu showed no trace of these dendrites, and so the surfaces of several were rubbed down and polished. In each case their structure was the same as that of the centre of the alloy, which shows that these dendrites have split up and rearranged themselves after solidification, and all that remains of them is this surface structure. Casting makes the structure very minute, and about 73 per cent. Cu traces of the skeleton crystals can be seen in the centre of the ingot. They appear dark and structureless, as if they had been unable to resolve themselves into their two constituents.

75 *to* 100 *per cent. Copper.*—When 76 per cent. copper is present, two new constituents make their appearance and the alloy assumes a yellow tint. In section we find yellow grains, surrounded by a bright white border, set in the second eutectic, in which small bright white grains also occur. As the total copper is increased, the yellow grains increase, forming dendrites and skeleton crystals, the white borders and grains merge together and the eutectic decreases till at about 90 per cent. it disappears. The yellow grains become darker and darker (contain less and less tin in solid solution). The light borders diminish and disappear, about 95 per cent. leaving copper dendrites behind. These dendrites vary in composition from centre to outside, and so the centre etches a darker colour. They darken with increase of copper until 100 per cent. is reached. Casting tends to make the copper grains solidify, containing a considerable quantity of tin. In this way the eutectic can be made to disappear considerably below 90 per cent Cu. Quenching shows that the upper break corresponds to the solidification of the copper; break 2 to the solidification of the groundmass which splits up into a eutectic when branch *e* is reached. Fig. 6 contains 80 per cent. Cu furnace-cooled, whilst Fig. 7 shows the surface of the same and also that with this percentage of copper the dendrites of copper have directed the formation of the surface skeletons. Fig. 8 is the same alloy quenched below first break. The dendrites of copper are seen set in a structureless matrix. Fig. 9 is the same alloy quenched below the second break. The dendrites of copper (light, because of a different etching process) are seen, set in a fibrous matrix—the eutectic of which the formation has been faced. Fig. 10 shows the same alloy cast. As its appearance would indicate, the alloy is very tough and cuts well.

It seems clear then that branch *e* of the cooling curve is one of change in the solid, and this conclusion has been proved beyond doubt by the beautiful work of Heycock and Neville published by the Royal Society. When one considers the many and distinct different structures in the series produced by quenching at different temperatures and by reheating and then quenching, it is quite evident that the changes which take place during the cooling of an alloy of copper and tin, especially in the neighbourhood of the second eutectic, are even more numerous than those of the carbon-irons.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Allen studentship, value 250*l.* for one year, for research in connection with medicine, mathematics, physics and chemistry, biology and geology, or moral science, will be filled up at the end of the present term. It is open to graduates under the age of twenty-eight on January 8.

Principal E. H. Griffiths, F.R.S., of Cardiff University College, has been approved for the degree of Doctor of Science.

The Rede lecture will be delivered next term by Prof. Osborne Reynolds, F.R.S., of Owens College, Manchester.

Mr. W. N. Shaw, F.R.S., will give three lectures, on February 13, 20 and 27, on the physics of the ventilation of buildings.

Prof. Tilden, F.R.S., has been appointed an elector to the chair of chemistry; Lord Rayleigh, F.R.S., an elector to the chairs of chemistry and of mechanism; Dr. Hill, to the anatomy chair; Mr. F. Darwin, F.R.S., to the botany chair; Dr. Hinde, F.R.S., to the geology chair (Woodwardian); Sir G. G. Stokes, F.R.S., to the Jacksonian and Cavendish chairs; Dr. D. MacAlister, to the Downing chair of medicine; Dr. Hugo Müller, F.R.S., to the chair of mineralogy; Prof. E. Ray Lankester, F.R.S., to the chair of zoology and comparative anatomy; Prof. McKendrick, F.R.S., to the chair of physiology; Lord Lister, F.R.S., to the chair of pathology; and Prof. Marshall Ward, F.R.S., to the chair of agriculture.

Dr. J. Reynolds Green, F.R.S., has been elected to a fellowship at Downing College.

THE University College, Bristol, does not receive the generous support given to similar colleges elsewhere, but the report of the council for the session 1900–01 shows that much valuable work has been done in spite of limited means and opportunities. Important papers have been published by various members of the scientific staff and others are in progress. The clinical and bacteriological research laboratory, which has been at work under Prof. Stanley Kent for little more than a year, has, among other matters, been able to afford valuable aid to the Medical Officer of Health in reporting upon the presence of plague in-

fection in material submitted for examination. In one case, plague infection was found to be undoubtedly present, and the report of the laboratory upon it was made immediately. In a second case the appearances presented were suspicious, and the report of the laboratory enabled precautions to be taken to safeguard the city in the event of true plague appearing. More accommodation for this kind of research work is required, as there is no lack of persons willing to undertake it. The same remark applies to other departments of the College. If people of means in Bristol and the neighbourhood took any interest in educational progress, the establishment of the University of Birmingham, and the movement in favour of other universities of a similar kind, would inspire them to action in the same direction. There is room for a University of the West of England, and if Bristol does not rise to its opportunity another city of the west will take its place. The subject has been brought up over and over again, and only a few days ago Mr. Haldane spoke in favour of it at the annual dinner of the University College Colston Society. The Bishop of Hereford also alludes to it at the end of the present report. But the rich citizens of Bristol do not seem to understand what has been done by private persons for higher education in cities like Liverpool, Birmingham and Manchester, or if they know they apparently have no desire to follow the example. There will have to be a complete awakening of the spirit of pride in local resources for education and research before Bristol can make any real movement towards a University of the West of England.

SCIENTIFIC SERIALS.

Transactions of the American Mathematical Society, vol. iii. No. 1, January.—On a class of automorphic functions, by J. L. Hutchinson. In Burkhardt's "Ueber die darstellung einiger fälle der automorphen primformen durch Specielle Thetareihen," the following monodromy group of the Riemann surface, $y^3 = (x-\alpha_1)(x-\alpha_2)(x-\beta_1)^2(x-\beta_2)^2$, is considered, and he shows how a certain prime form which is automorphic for the group can be expressed by a theta series. Further results are here given concerning the group and the functions belonging to it, the chief object being to obtain explicit analytic formulæ by means of which all functions of the group can be represented. To this end the theta-fuchsian functions of Poincaré are introduced, and their expressions in terms of the hyperelliptic theta series deduced.—Concerning the existence of surfaces capable of conformal representation upon the plane in such a manner that geodetic lines are represented by a prescribed system of curves, by H. F. Stecker, is in continuation of a previous paper under nearly the same title (vol. ii. p. 152).—Zur erklärung der Bogenlänge und der inhaltes einer Krummen fläche, by O. Stoll (*cf.* the author's "Grundzüge der Differential- und Integralrechnung," Bd. 2, and *Math. Ann.*, Bd. 18).—The groups of Steiner in problems of contact, by Dr. L. E. Dickson, gives an elementary proof of Jordan's ("Traité," pp. 229–249). Reference is given to Steiner and Hesse (*Journal für Math.*, vol. xlix. (1855) and vol. lxiii. (1864), and to papers by the author (*Bulletin* Amer. Math. Soc., vol. iv., and the *American Journal of Mathematics*, vol. xxiii. pp. 337–377).—Quaternion space, by A. S. Hathaway, follows up Stringham's work in vol. ii. p. 183, but frequent reference is made to Clifford's paper on biquaternions. Stringham deals analytically with the equations of loci and develops the geometry by the interpretation of those equations; the author uses a more synthetic method, which interprets the quaternion symbols themselves instead of the equations between them. It is this divergence which constitutes the general difference between the methods of Cayley and Tait. Clifford stated the synthetic view in his Further note on biquaternions.—Reciprocal systems of linear differential equations, by E. J. Wilczynski, arrives at interesting results in connection with previous papers (*Transactions*, vol. ii. No. 4; *American Journal of Mathematics*, vol. xxiii.).—On the invariants of quadratic differential forms, by C. N. Haskins, investigates, by means of Lie's theory of continuous groups, the problem of determining the number of invariants of the general quadratic form in n variables. Numerous references occur in the paper.—On the nature and use of the functions employed in the recognition of quadratic residues, by Dr. E. McClintock, refers to Tannery, "Leçons d'Arithmétique," Bachmann, "Elemente der Zahlentheorie," and to Baumgart, "Ueber der Quadratische Reciprocitätsgezetz."—A determination of the number of real and imaginary roots of the hypergeometric series, by E. B. Van Vleck. Concisely we must refer to Klein (*Math. Ann.*, vol. xxxvii. p. 573) for the number of the roots of the equation considered between 0 and $-\infty$. Mr. Van Vleck claims that he gives, for the first time, the number of imaginary roots. Numerous references and diagrams (six and a page of sixteen) accompany the text.—The second variation of a definite integral when one end-point is variable, by G. A. Bliss. The method which the author applies to the discussion of the case in which one end-point moves on a fixed curve is closely analogous to that of Weierstrass ("Lectures on the Calculus of Variations," 1879). In the present case terms outside of the integral sign are taken into consideration. Then, as a result of the discussion, the analogue of Jacobi's criterion is derived, defining, apparently in a new way, the critical point (Kneser's "Brennpunkt") for the fixed curve along which the end-point varies. Then the relation between the critical and conjugate points is discussed.—On the projective axioms of geometry, by E. H. Moore, contains a consideration of the axioms called by Hilbert ("Grundlagen der Geometrie") the axioms of connection and of order, and by Schur ("Über die Grundlagen der Geometrie") the projective axioms of geometry. There are several citations of authorities, such as Peano, Pasch and Ingrami.

Bulletin of the American Mathematical Society, January.—Note on Mr. George Peirce's approximate construction for π, by E. Lemoine. This article gives four constructions suggested by a discussion of Mr. Peirce's which we have previously noticed (*Bulletin*, July, 1901). The relative theoretic exactness is determined by calculating the true value of the length which in each case approximately represents π. The solutions are worked out by aid of the geometrographic notation. A slight sketch of this method, sufficient for the present purpose, is given. (For a fuller account, reference may be made to M. Lemoine's "La Géométrografie" or to the "Traité de Géométrie" in the *Archiv. der Mathematik und Physik*, April and May, 1901, vol. i., Gauthier-Villars). There is also appended a close approximation to the trisection of an angle by C. Störmer worked by the same method. There are several diagrams.—Concerning the elliptic $\wp\,(g_2, g_3, z)$ functions as coordinates in a line complex, and certain related theorems, by Dr. H. F. Stecker, is an application of the coordinates to the Kummer surface and certain other configurations (*cf.* Klein, *Math. Ann.* vol. v., pp. 294–5).—A short note on the Abelian groups which are conformal with non-Abelian groups follows, by Dr. G. A. Miller. Dr. S. E. Slocum writes on the infinitesimal generators of certain parameter groups. The paper opens with a *résumé* of the method employed by the author on pp. 97–103 of the *Proceedings* of the American Academy of Arts and Sciences, vol. xxxvi., and then proceeds to give tables in which are enumerated all possible types of structure of two-, three- and four-parameter complex groups as given by Lie, and under each structure are given the symbols of the infinitesimal transformations which generate the parameter group corresponding to that structure, obtained by the method referred to above (*cf.* Lie, "Continuierliche Gruppen," pp. 565–589; "Transformations Gruppen," vol. iii., pp. 713–730).—Notices follow of the "Einführung in die Theorie der Differential gleichungen mit einer unabhängigen Variabeln" of Dr. L. Schlesinger and of Prof. Hatzidakis's "εἰσαγωγὴ εἰς τὴν 'Ανωτέραν 'Αλγέβραν."—The usual information of interest to mathematicians follows in the form of notes and new publications.

Annals of Mathematics, January.—Some applications of the method of abridged notation, by Maxime Bôcher, is an interesting elementary paper the nature of which may be gathered from an illustration. Let the sides of a triangle be $u=0$, $v=0$, $w=0$ (where $u \equiv x\cos\alpha + y\sin\alpha - p$), then $u-v=0$, $v-w=0$, $w-u=0$ are the bisectors of the angles, and as the sum of the sinisters vanishes identically we get the property of the bisectors of the angles cointersecting in a point. If, again, $u \equiv x^2+y^2+ax+by+c=0$ and so on, we can show that the common chords of three circles meet in a point. The author then proceeds to the proof of Desargues' theorem and thence to generalisations for four circles and for curves of the nth order, and extends, by suggestion, his results to surfaces.—On the roots of functions connected by a linear recurrent relation of the second order, by M. B. Porter, reproduces in part some unpublished theorems of Sturm (*cf.* "Liouville," vol. i.), and shows how, by means of the Cauchy-Lipschitz theorem for the existence of solutions of a differential equation, it is possible to establish

rigorously the analogous theorems, so far as they exist, for the homogeneous linear differential equations of the second order. The article closes with some applications.—Space of constant curvature, by F. S. Woods, is an attempt to present Riemann's ideas (*cf.* the "Ueber die Hypothesen, welche der Geometrie zu Grunde liegen") in an elementary form. The paper is given in part and is useful, in addition to the results worked out, for its bibliographical references.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 23.—"The Affinity of Tmesipteris with the Sphenophyllales." By A. P. W. Thomas, M.A., F.L.S., University College, Auckland, New Zealand.

In the present paper the author deals with the nature of the synangium of Tmesipteris, as based on the study of variations observed in the sporophyll, beyond the limits already recorded by Bower.

The term "sporophyll" is used to denote the whole fertile structure, the term "synangium" restricted to the sporangiophore. Three types of variation are recorded, viz. (1) that of repeated dichotomy of the sporophyll with two to three synangia; (2) that in which the synangium is raised upon a pedicel or stalk; (3) that in which the synangium is replaced by a leaf-lobe of normal appearance. It is shown that abnormality in the sporophylls and synangia, which commonly occurs at the beginnings or ends of the fertile zones, is not found in cases where the sporophyll shows excessive leaf development. In these it occurs rather towards the middle region, and it is inferred that if the nutritive conditions remained equally satisfactory throughout, the whole sporophyll series should show repeated dichotomy.

Concerning the second type of variation, the synangium is found to have become so revolved upon a transverse axis that its longitudinal groove faces outwards between the leaf-lobes, assuming a position the more favourable to dispersal of the spores. In the third type the leaf is shown to be forked, although the synangium, if present at all, exists only in an abortive form. From the fuller study of this, the author suggests that the synangium is the morphological equivalent of a ventral leaf-lobe.

Passing to questions of classification, the author refers to the difficulties in reconciling the sporangium-bearing structures of the Psilotæ with those of the typical Lycopodinæ. He enters into a comparison with the extinct Sphenophyllales, with especial reference to Bowmanites and Cheirostrobus, and concludes that the relationships of Tmesipteris and Psilotum with this group are perhaps even closer than is supposed by Scott.

In an addendum, received since this paper was announced, the author makes good his desire to deal extensively with the Psilotum sporophyll, the leaves of which, though greatly reduced and xerophytic, are shown to be essentially similar to those of Tmesipteris.

Society for Psychical Research, January 31.—Dr Oliver Lodge, F.R.S., delivered his presidential address. Dealing first with the phenomena of trance, lucidity and clairvoyance, he expressed the opinion that much more information was required before we could even formulate the problems raised by these faculties. With regard to physical phenomena, he thought much of the extra difficulty of accepting evidence for unusual phenomena was due to the *a priori* notion that such occurrences are contrary to natural law. We cannot, however, clearly tell that they are contrary to natural law; they are only contrary to and supplementary to our usual experience. The objection of science to psychical research is mainly due to the fact that it regards psychical phenomena as unintelligible. It is accustomed to simplify its problems by the method of abstraction and has got into the habit of thinking that it actually excludes disturbing causes; the abstraction cannot really exclude from the universe anything apparently disorderly. Theoretically, this is universally admitted; practically science has excluded psychical phenomena from its experimental area. He was not prepared to say that physical phenomena such as materialisations, the passage of matter through matter, and levitation were impossible and absurd, so that no testimony ought to produce any effect on our incredulity. Extreme caution was necessary and full control must be allowed to the observers. His personal belief was that man survived death, and this belief had been produced by scientific evidence. He did not attribute the physical phenomena of spiritualism to the agency of the departed, but was disposed to regard trance utterances as in some cases due to telepathic communication with some unconscious stratum of a departed person.

Royal Microscopical Society, January 15.—Mr. Wm. Carruthers, F.R.S., president, in the chair.—This being the annual meeting of the Society, the president gave an address on the scientific work of Nehemiah Grew, from 1641–1712, whom he defended from the charges of plagiarism which had been brought against him in respect to his discoveries as to plant structure.—Mr. E. A. Parsons gave an exhibition of malaria parasites under a number of microscopes, lent for the occasion by Messrs. Chas. Baker.—Messrs. Ross exhibited their new form of standard microscope, designed specially for the use of medical students, fitted with a new form of fine adjustment. Messrs. Ross also exhibited a simple lens for dark ground illumination. It consists of a meniscus lens bored through its centre to receive a spot made of vulcanite provided with a stem to drop into the hole in the centre of the lens.

Geological Society, January 22.—Mr. J. J. H. Teall, V.P.R.S., president, in the chair.—The fossiliferous Silurian beds and associated igneous rocks of the Clogher Head district (county Kerry), by Prof. S. H. Reynolds and Mr. C. I. Gardiner. The authors give a detailed description of the coast from Dunquin past Clogher Head to Coosglass (south of Sybil Point), and of the western side of Smerwick Harbour. They next deal with the inland exposures, which are not very frequent, but include considerable rock-masses at Croaghmarhin and Minaunmore Rock. The rocks consist of sandstones, slates, calcareous flags, ashes and ashy conglomerates, rhyolitic lava-flows and various intrusive rocks. The general structure is an S-shaped fold, inverted towards the north so that the dip of the beds is approximately south-easterly, and the oldest beds occur to the north, at Coosglass. Both anticline and syncline are faulted, and a patch of Old Red Sandstone is caught in under the synclinal thrust at Coosmore. Fossils, mainly corals, brachiopods, lamellibranchs and gasteropods are fairly abundant; but trilobites are rare and graptolites absent. The whole of the fossiliferous rocks are of Silurian age; the majority of those exposed on the coast are of Wenlock or Wenlock-Llandovery age, while the majority of those exposed inland are of Ludlow age.—A process for the mineral analysis of rocks, by Prof. W. J. Sollas, F.R.S. The method proposed is to obtain a quantitative estimation of the mineral composition of a rock, and from the known composition of the minerals to calculate the percentage-composition of the rock. The specific gravities of the minerals are first determined by means of a diffusion-column of methylene-iodide and beads of known specific gravity, and the presence or absence of particular minerals settled for a certainty. Next, the separation of the minerals in a weighed quantity of the powdered rock is undertaken by means of a special separator, the method being illustrated by the example of a rock containing orthoclase (sp. gr. 2·56), quartz (2·65), andesine (2·67), biotite (3·1), pyroxene (3·3) and magnetite. The first separation would be with a liquid of sp. gr. 2·885, the mean of that of andesine and biotite; the next with a liquid of sp. gr. 2·66; the next 2·605, and so on for the other constituents. The separated minerals are dried and weighed, the loss distributed, and the analysis checked by comparing the specific gravity of the rock in bulk with that calculated from the specific gravity and proportion by weight of its constituents.

DUBLIN.

Royal Irish Academy, January 13.—Prof. R. Atkinson, president, in the chair.—Prof. T. Johnson communicated, on behalf of the fauna and flora committee of the Royal Irish Academy, a paper by Mr. W. West and Prof. G. S. West entitled "A Contribution to the Freshwater Algæ of the North of Ireland." This paper gives the results of the examination of material collected by the authors in 1900 and 1901 in Lough Neagh and district, and in co. Donegal. 139 genera, 604 species and 106 varieties are recorded. Of these some twelve, described and illustrated, have been hitherto unknown, twenty-four others are new to the British Isles, many others new to Ireland, and the distribution of yet others, recorded by the late Mr. W. Archer, F.R.S., and Rev. E. O'Meara, is largel

extended. The paper is illustrated by some ninety figures. Three desmids, *Micrasterias furcata*, Ag., *Staurastrum Arctiscon* (Ehrenb.), Lund., and *Staurastrum longispinum* (Bail.), Arch., are of particular interest in that they appear to be confined to the western shores of the British Isles—being known only as occurring in the small lakes in the hilly districts of Connemara and Donegal in Ireland, the lakes of the Snowdon range in North Wales, and from similar situations in the extreme north-west of Scotland. No species of Vaucheria were found, and *Botrydium granulatum* is recorded for the first time in Ireland.

Royal Dublin Society, December 18, 1901.—Dr. W. E. Adeney in the chair.—Sir Howard Grubb, F.R.S., on some new forms of geodetical instruments. The author applies the principle he recently described (*Scientific Transactions*, Royal Dublin Society, vol. vii. p. 321) for gun sights for large and small ordance to various forms of geodetical instruments.—Prof. J. Joly, F.R.S., on sedimentation experiments and theories. T he rates of settlement of suspensions consisting of 5 grammes of finely powdered solid in 12 c.c. of water containing ions in various degrees of concentration, indicate that above a certain concentration the rate of fall of the surface of the suspension is fairly independent of the degree of concentration. Below certain concentrations (about five times greater for monad positive ions than for diad) a distinct surface to the descending suspension fails, and the sediment is only seen to collect from the bottom of the vessel upwards. A suspension precipitated at a concentration so low as to be near the point of failure to show surface will, if re-shaken, not again precipitate with a distinct surface. On removing the electrolyte from such an "exhausted" suspension after it has stood sufficiently long to settle, it is found that the liquid is as effective as at first in producing surface if a fresh sample of the powder is used. On the other hand, the original powder will not again show surface when treated with fresh electrolyte of the same strength, but it will require a much more concentrated electrolyte to do so. The failure is therefore to be traced to some alteration in the solid particles. On testing the fresh powder it is found that this is negative towards distilled water; the used powder is apparently quite neutral towards its salt solution. An explanation of sedimentation is advanced, based on the low specific inductive capacity of the solid particle compared with the specific inductive capacity of the water, the charges on the ions being assumed to exert an expulsive action consequent on the increased energy required to establish the electric field in the medium of low specific inductive capacity. In other words, the solid particles have a de-ionising influence, and experience a reaction in consequence, which will tend to retain in juxtaposition particles which from any cause are once approximated. A principal cause of aggregation upon first precipitation is to be ascribed to the negative sign of the particles leading to motions, all in the end favourable to aggregation, seeing that the state of aggregation is alone stable in the medium. On second disturbance the particles are neutral, and aggregates are not formed with sufficient rapidity to lead to a general and simultaneous descent of the suspension.—Lord Rosse, K.P., F.R.S., exhibited working models of apparatus for turning aside leaves in the water supply of a turbine.—Sir Howard Grubb exhibited the cœlostat constructed for the Royal Dublin Society and used at the solar eclipse of 1900.

January 22.—Prof. W. F. Barrett, F.R.S., in the chair.—Mr. W. E. Wilson, F.R.S., on the nebulæ surrounding Nova Persei.—Prof. Barrett, Mr. W. Brown and Mr. R. A. Hadfield, on researches on the electric properties of an extensive series of alloys of iron.—Mr. Richard J. Moss, on an improved volumetric method for the determination of sugar. In Pavy's modification of Fehling's method, cupric oxide is reduced in presence of a a large excess of ammonia, which prevents the precipitation of cuprous oxide. The temperature of the boiling liquid varies from about 70° C. to 90° C., and the rate of reduction varies to a corresponding extent. The author overcomes this objection to the method by using a much smaller quantity of ammonia, and conducting the titration under pressure, at the temperature of boiling water. The reduction of the cupric oxide is apparently instantaneous, and the results are very sharp and constant.

PARIS.

Academy of Sciences, February 3.—M. Bouquet de la Grye in the chair.—On a new synthesis of formic acid, by M. Henri Moissan. Potassium hydride absorbs carbonic acid at the ordinary temperatures producing potassium formate. The formation of formic acid was confirmed by the production of the free acid, which showed the ordinary reducing properties, and by the preparation and analysis of the crystallised lead salt. Carbon monoxide also reacts with potassium hydride at 150° C., potassium formate being formed and carbon set free.—On certain cases of adherence of a viscous liquid to the solid with which it is in contact, by M. P. Duhem. —New observations on the folds of the phosphatic chalk in the Somme, by M. J. Gosselet. The strongly inclined layers of phosphatic chalk discovered at Éaves in 1896 might have been looked upon as a local accident, but the same facts have now been noticed at Hargicourt, and at two places at a much greater distance, Éclusier, between Peronne and Albert, and at Crécy in Ponthieu. These layers are small, but are too widely extended to be the result of a purely local accident. The facts observed confirm the views of M. Marcel Bertrand on the slow and progressive formation of the folds of a geological basin.—Remarks by M. Albert Gaudry on presenting to the Academy a work on the comparison of the teeth of man and the anthropomorphic apes.—M. Alfred Picard was elected a free member in the place of the late M. de Jonquières.—Observations of the sun made at the Observatory of Lyons with the Brunner 16 cm. equatorial during the second quarter of 1901, by M. J. Guillaume. Tables are given showing the number of spots, their distribution in latitude and the distribution of the faculæ in latitude.—Researches on the Hertzian waves emanating from the sun, by M. Charles Nordmann. The experiments described were carried out at the Grand-Mulets on Mt. Blanc, the weather conditions being too unfavourable to utilise the observatory at the summit. The conclusions drawn from the experiments are that the sun does not emit electric radiations capable of affecting radioconductors, or that, if they are given off, they are completely absorbed by its atmosphere or by the upper portions of the terrestrial atmosphere.—Some remarks on entire functions, by M. Edmond Maillet.—The variation of the electromotive force and the temperature coefficient of the Daniell cell with the concentration of the zinc sulphate solution, by M. J. Chaudier. Starting with a saturated solution, the electromotive force of a Daniell cell increases when the concentration of the zinc sulphate diminishes, passes through a maximum for a $\frac{1}{2}$ per cent. solution, and then again decreases for smaller concentrations. The temperature coefficient, which at first is negative, increases and becomes zero at a concentration of between 7 and 8 per cent.; but, after having attained a positive maximum, it falls off and vanishes a second time for a $\frac{1}{2}$ per cent. solution. From this it follows that the Daniell cell furnishes a standard of electromotive force which is independent of the temperature when it is made up with a saturated solution of copper sulphate and a 7·5 per cent. or $\frac{1}{2}$ per cent. solution of zinc sulphate.—On the galvanometric observation of distant storms, by M. J. J. Landerer. With the arrangement described the electrical disturbances due to distant storms have been observed up to a distance of 240 kilometres.—Comparison between the properties of hydrogen selenide and those of hydrogen sulphide, by MM. de Forcrand and Fonzes-Diacon. Data for hydrogen sulphide are given in the present paper. The boiling-point at a pressure of 773 mm. was found to be −61° C., and the melting-point −86° C. The density of liquid sulphuretted hydrogen at its boiling point is 0·86. A comparison with the data previously given for hydrogen selenide shows great analogies between the two compounds They have practically identical molecular volumes, their boiling-points expressed as fractions of their critical temperatures are the same, and the ratio of latent heat of vaporisation to the boiling-point is also nearly the same for the two gases.—On the action of lithium-ammonium on antimony, and on the properties of the antimonide of lithium, by M. P. Lebeau. Lithium-ammonium reacts upon antimony, giving a compound of the formula $SbLi_3$, identical with that previously obtained by electrolysis. This substance dissolves in liquid ammonia, uniting with it to form the compound $SbLi_3NH_3$. Lithium antimonide is less fusible than either of its constituents, and possesses very energetic reducing properties.—On oxy-isopropyl-hypophosphorous acid, by M C. Marie.—On the hydrolysis of pyromucic urethane, by M. R. Marquis.—The action of nitric acid upon trichloro- and tribromo-veratrol, by M. H. Cousin. The action of nitric acid upon these substituted veratrols gives rise to mono-nitro-derivatives, the reaction being altogether different from the action of nitric acid upon the tetra-chloro- and tetra-

bromo-veratrols.—On some derivatives of glutamine, by M. E. Roux. A description of the mode of preparation and properties of various derivatives of glucamine.—The action of aluminium chloride on some anhydrides in chloroform solution, by M. Marcel Desfontaines.—On the opisthobranchs collected in 1883 by the Talisman expedition, by M. A. Vayssière.—The lymphomyeloid constitution of the conjuctive stroma of the testicle of the young in *Raja clavata*, by M. A. Policard.—On the homologies of the interstitial cell of the testicle, by M. P. Stéphan.—On the structure of the tuberculous roots of *Thrincia tuberosa*, by MM. A. Maige and C. L. Gatin.—On the *Ksopo* or *Tanghin de Ménabé*, the poison of *Menabea venenata*, by M. E. Perrot.—The chemical study of Flamanville granite, by M. A. Leclère. It is shown from the analyses given that the composition of an eruptive rock may differ very considerably in certain cases from that of the initial magma.—On the transformation of fatty materials into sugars in oleaginous seeds during germination, by M. P. Mazé. The experiments afford confirmation of the view that the digestion of fatty matters in the seed during germination is made with a slow fixation of oxygen, and, probably, with a slight loss of carbon.—Researches on the working of antagonistic muscles in voluntary movements, by M. I. Athanasiu.—Remarks on a note of M. Pizon on a mechanical theory of vision, by M. Raphael Dubois. In reply to the criticism of M. Pizon, the author maintains that his mechanical theory of vision is confirmed, not only by the researches of Deren Stort and Engehlmann, but also by those of Charpentier and d'Arsonval.—The vine and *Coepophagus echinopus*, by M. S. Jourdain. MM. L. Mangin and P. Viala have correlated a certain disease of the vine with the presence of a certain acarian, *C. echinopus*. The author advances reasons for doubting the correctness of this view, and believes that curative measures directed against this acarian will be useless.—A new case of trichosporia observed at Nancy, by M. Paul Vuillemin.—Contribution to the knowledge of the action of lecithine on the typical elements of the blood, by MM. H. Stassano and F. Billon.—The etiology of the cattle plague, by MM. Nicolle and Adil-Bey.—On a fall of rain observed at Périers, by M. Sebillaut. The rain-water from the shower in question was found to contain chalk, sulphates, chlorides and silica, the latter in sufficient quantity to cover the leaves of trees with a siliceous layer.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 13.

ROYAL SOCIETY, at 4.30.—On the Sub-Mechanics of the Universe: Prof. O. Reynolds, F.R.S.—On Chemical Dynamics and Statics in Light: Dr. M. Wilderman.—Preliminary Note on a Method of Calculating Solubilities, Equilibrium Constants of Chemical Reactions, and Latent Heat of Vaporisation: Dr. A. Findlay.—The Refractive Indices of Fluorite, Quartz and Calcite: J. W. Gifford.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Researches on the Electrical Conductivity and Magnetic Properties of upwards of 100 different Alloys of Iron: Prof. W. F. Barrett, F.R.S., and W. Brown.—On some Conclusions deduced from the preceding Paper: Prof. W. F. Barrett, F.R.S.

MATHEMATICAL SOCIETY, at 5.30.—(1) On the Density of Linear Sets of Points; (2) On Closed Sets of Points defined as the Limit of a Sequence of Sets of Points: W. H. Young.—On Plane Cubics: Prof. A. C. Dixon.—On Boussinesq's Problem: Prof. H. Lamb, F.R.S.—On the Wave Surface of a Dynamical Medium, Æolotropic in all Respects: Prof. T. J. Bromwich.—On Quantitative Substitutional Analysis (second paper): A. Young.

FRIDAY, FEBRUARY 14.

ROYAL INSTITUTION, at 9.—Magic Squares and other Problems on a Chess Board: Major P. A. MacMahon, F.R.S.

PHYSICAL SOCIETY, at 5.—Annual General Meeting.—Address by the President, Prof. S. P. Thompson, F.R.S.—Mr. T. H. Littlewood will exhibit an Atwood's Machine.

ROYAL ASTRONOMICAL SOCIETY, at 3.—Annual General Meeting.

MALACOLOGICAL SOCIETY, at 8.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Some Public Health Aspects of the Question of Sewage Disposal: C. Johnston.

SATURDAY, FEBRUARY 15.

ROYAL INSTITUTION, at 3.—Some Electrical Developments: Lord Rayleigh, F.R.S.

MONDAY, FEBRUARY 17.

SOCIETY OF ARTS, at 8.—Personal Jewellery from Prehistoric Times: Cyril Davenport.

IMPERIAL INSTITUTE, at 8.30.—The Obstacles to Development in West Africa: Dr. C. F. Harford-Battersby.

VICTORIA INSTITUTE, at 4.30.—The Physical History of the Norwegian Fjords: Prof. Edward Hull, LL.D., F.R.S.

TUESDAY, FEBRUARY 18.

ROYAL INSTITUTION, at 3.—The Cell: its Means of Offence and Defence: Dr. A. Macfadyen.

ZOOLOGICAL SOCIETY, at 8.30.—On *Mustela palaeattica* from the Upper Miocene of Pikermi and Samos: Dr. C. I. Forsyth Major.—On Two New Genera of Rodents from Potosi, Bolivia: Oldfield Thomas, F.R.S.—On some Characters distinguishing the Young of various Species of Polypterus: G. A. Boulenger, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Electrical Traction on Railways: W. M. Mordey and B. M. Jenkin.

ROYAL STATISTICAL SOCIETY, at 5.—A Statistical Review of the Income and Wealth of British India: J. Atkinson.

WEDNESDAY, FEBRUARY 19.

SOCIETY OF ARTS, at 8.—The Use of Balloons in War: E. H. S. Bruce.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Report on the Phenological Observations for 1901: E. Mawley.—La Lune mange les Nuages—a Note on the Thermal Relations of Floating Clouds: W. N. Shaw, F.R.S.

CHEMICAL SOCIETY, at 5.30.—Enzyme Action: A. J. Brown.—On the Velocity of Hydrolysis of Starch by Diastase, with some Remarks on Enzyme Action: H. T. Brown and T. A. Glendinning.—Polymerisation Products from Diazoacetic Ester: O. Silberrad.—Condensation of Phenols with Esters of Unsaturated Acids, Part VII.: S. Ruhemann and H. E. Stapleton.—The Union of Hydrogen and Oxygen: H. B. Baker.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Polarising with the Microscope: E. M. Nelson.

THURSDAY, FEBRUARY 20.

ROYAL SOCIETY, at 4.30.

LINNEAN SOCIETY, at 8.—(1) On some Gasteropoda (*Limnotrochus* and *Chitra*) from Lake Tanganyika, with the Description of a New Genus; (2) On the Nyassa Vivipara and its Relationship to Neothauma: Miss L. Digby.—On the Fruit of *Melocarina bambusoides*, an Exalbuminous Grass: Dr. A. Stapf.—On a West Indian Sea Anemone, *Bunodeopsis globulifera*: Dr. J. E. Duerden.

FRIDAY, FEBRUARY 21.

ROYAL INSTITUTION, at 9.—Musical and Talking Electric Arcs: W. Duddell.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Annual General Meeting. Followed by discussion on Modern Machine Methods, with Reply by the Author, H. L. F. Orcutt, and, time permitting, Fencing of Steam- and Gas-Engines: H. D. Marshall.—Fencing or Guarding Machinery used in Textile Factories: S. R. Platt.—Protection of Lift-Shafts, and Safety Devices in connection with Lift-Doors and Controlling Gear: H. C. Walker.—Guarding Machine Tools: W. H. Johnson.

GEOLOGICAL SOCIETY, at 3.—Annual General Meeting.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

PLANARIANS AND THEIR ALLIES.

A Treatise on Zoology. Edited by E. Ray Lankester, M.A., LL.D., F.R.S. Part IV. "The Platyhelmia, Mesozoa and Nemertini." By Prof. W. Blaxland Benham, M.A., University of Otago, New Zealand. Pp. iv + 204. (London: A. and C. Black.) Cloth, 15*s.* net; paper covers, 12*s.* 6*d.* net.

IT is a new thing for a whole volume of a zoological treatise to be devoted to the two phyla, Platyhelmia (Turbellaria, liver-flukes and tapeworms) and the Nemertea (long sea-worms), which Prof. Benham describes in the work before us. For a number of reasons they are not popular groups of animals. The free-living forms are delicate and their very identification is attended with considerable difficulty, and needs mechanical skill and anatomical knowledge. The parasitic forms add gruesome associations to these troubles, so that it is only the unfortunate patient, the doctor and the scientific agriculturist who have in any sense a working acquaintance with flukes and tapeworms. Very few zoologists know much about them except in such places as Italy, parts of Germany and Egypt, where their unpleasantly common occurrence has created the necessity for a thorough investigation of the modes of infection and of the methods for obtaining immunity from their attacks. Hence it is that in most text-books these phyla have not been given that serious and thorough attention which is afforded them in Prof. Ray Lankester's "Treatise of Zoology." We have here a compact, lucid and scholarly summary of the anatomy, life-histories and classification of the parasitic flatworms.

With such an unprecedented amount of room at his disposal Prof. Benham would have done well to have brought his opening chapter (on the Turbellaria or Planarians) more up to date in its anatomical, physiological and bionomical aspects. It was written and has been in proof some years, as the editor tells us, but we cannot accept the soothing remark that "the editor is satisfied that no important omissions due to this fact occur in the book." Von Graff's splendid monograph on land-planarians (1899) is barely alluded to, and his striking results on the anatomy and distribution of these animals are omitted, nor are any of his figures introduced. The work by Hesse on the eyes of Turbellaria is merely mentioned, but his important results are passed over in silence. The paper by Dörler (1900) on parasitic Vorticidæ, in many ways a striking piece of work, is entirely overlooked. The application, by Rina Monti, of the "Golgi-method" to the detection of nerve-elements of Planarians (1896, 1900), the work by Prof. E. L. Mark on Polychærus (1892 !), the many papers by the school of comparative physiologists and more particularly by Parker and by Prof. Loeb, are a few of the more striking omissions which occur to us. In some of these cases we may excuse Prof. Benham (but not his editor), since his residence in New Zealand may preclude access to the "Zoologische Jahresberichte" of the last four years; but even this allowance cannot cover the lack of information on topics such as colour, distribution and variation, upon which the evidence yielded by Turbellaria is not inconsiderable and is of great and growing interest.

The chapters succeeding that on the Turbellaria are far more satisfactory, though there are several omissions of important or useful papers, such as Looss' work on Egyptian Trematodes and the publications by Dr. Stiles and other members of the Washington Bureau on the parasites of domestic animals. To the student of anatomical zoology the sections on the "cuticle," "parenchyma," and the life-histories and their interpretation, will be a clearer guide to the nature of these problems than can be found in any other text-book.

As to the nature of the cuticle or investing membrane of Trematodes and Cestodes, Prof. Benham concludes from the researches of Blochmann and Kowalewski that the outer part of this structure is a true cuticle secreted by epidermal cells. In the adult parasite, however, these cells no longer form an epithelium, and their true nature is further disguised by the fact that they lose their primitive connection with the cuticle and sink into the parenchyma through the basement-membrane *pari passu* with an outward migration of cells of the parenchyma. These changes are illustrated by an excellent figure from Blochmann's memoir.

From an economic as well as from a strictly zoological standpoint, the interest of Trematodes and Cestodes centres in the life-history, which becomes progressively complicated in each group. There may be in the history of one parasite two successive larval stages passed in different hosts. Each stage is capable of reproducing many generations of its kind and then suddenly giving rise to the later larval form or (in the case of the latter) to the adolescent stage, which grows to maturity in the final host. The distinguishing feature of the process is the power of multiplication of the parasite while it is still a larva, and it is on the nature of this process that difference of opinion exists. The older writers regarded it as an asexual mode of reproduction, as a kind of budding; and they emphasised the alternation of these larval asexual generations with the adult sexual generation. The tendency of modern research has been to regard the larval generations, not as asexual, but as produced by the development of unfertilised eggs, in fact as cases of juvenile parthenogenesis; so that the life-history may on this view be summarised as a series of sexual generations, of which those which occur in the larval stages are parthenogenetic and that which subvenes in the adult worm is either self- or cross-fertilised.

To this modern view Prof. Benham assents, without, however, pointing out the necessity of obtaining critical evidence in its favour. The mature eggs of many animals differ from the body-cells in possessing only half the number of "chromosomes" which characterise the nuclei of the somatic-cells. It ought to be shown whether this holds true of the larval as well as of the adult "eggs" of Trematodes and Cestodes before the view that all the generations are sexual can be considered proved, and it would require still further evidence as to the number of the polar-bodies presumably extruded by the larval eggs before we could accept their parthenogenetic nature as demonstrated.

The concluding chapters on the Mesozoa and Nemertea

have been carefully brought up to date. They furnish a trustworthy account of the essential facts of anatomy and development, but as occurs in the case of the other groups described in this volume, the problem of their affinities is not set forth with that clearness which is so essential to its comprehension.

Considered as a whole, the volume has not that illuminating and suggestive value which distinguished the earlier volumes of the "Treatise." Nevertheless it will remain for some time the chief work of reference in the language on the anatomy and classification of the groups with which it deals.

PRIMARY BATTERIES.

Primary Batteries: their Theory, Construction and Use. By W. R. Cooper. Pp. 4+324. (London: *The Electrician* Printing and Publishing Co., Ltd., no date.) Price 10*s*. 6*d*. net.

MR. W. R. COOPER'S book directs attention to a subject which will always be of great historical interest on account of the remarkable stimulus given to electrical science by the discoveries of Galvani and Volta. At the present time, it is true, the primary battery has yielded to cheaper and more convenient sources of electrical energy, and the position which it holds in electrical engineering is comparatively insignificant. It is not improbable that before long it will be displaced from almost all practical applications of electricity and will only be found where the dynamo and accumulator are unavailable. It may, however, be some consolation to those who have not other means at hand to reflect that in the research by which Faraday laid down the fundamental laws of electrolysis he obtained current from a primary battery of the most elementary form. The advantage of amalgamating the zinc had been shown five years earlier (1828) by Kemp, but it was not until 1836 that the first effective depolarising cell, that of Daniell, was described; the invention of the Grove cell followed in 1839. The Leclanché cell, which did not appear until 1868, marks the only other development of the first importance.

In spite of the fact that Volta's discovery is more than a century old, the theory of the primary battery cannot be said to be in a very satisfactory state. Mr. Cooper devotes two chapters to this subject, the first of which deals chiefly with contact-force and the seat of the E.M.F. in the cell. Mr. Cooper, in summing up the various theories, states that "the whole matter (of the seat of the E.M.F.) is largely a question of definition, and is, therefore, of relatively small importance," a conclusion which is not likely to commend itself to those who are anxious to arrive at the truth. In the second chapter, the ionisation theory of Arrhenius is discussed and the calculations of the E.M.F. of a cell from the equations of Helmholtz and Nernst are compared, with results which are not very convincing in either case. The author then passes to a brief consideration of concentration and liquid cells (which are at present only of theoretical interest) and of the thermopile, which, he points out, on account of its high price is not likely to prove a serious competitor to the primary battery.

There follows what may be called the practical part of the book, in which the various types of existing cells are described and which contains much valuable information collected or directly obtained by the author. Cells are classified under three headings, one-fluid, two-fluid and dry cells. In the first division, the principal examples are the bichromate, Leclanché and copper-oxide cells. Some interesting tests carried out by the author show that in the bichromate cell the most suitable depolariser to use is chromic acid, which gives a discharge curve as good as that given by either sodium or potassium bichromate and is also more convenient and as cheap. The two-fluid cells include the Daniell, with its numerous derivatives, and the Grove and Bunsen cells, which on account of their high E.M.F. and low internal resistance are especially suitable where heavy currents are required. All the dry cells are modifications of the Leclanché and do not differ much from one another except in details of construction. It is somewhat surprising to find that, weight for weight, the dry cell is superior to the wet form of Leclanché. Against this must be set the somewhat higher initial cost and the advantage of the possibility of regenerating an exhausted wet cell, though this latter consideration, as Mr. Cooper shows, is in reality somewhat illusory. The usefulness of this part of the book is greatly increased by the numerous discharge curves which are included and by the many very clear drawings illustrating the various cells described.

The last two chapters deal with standard cells and carbon-consuming batteries. The standard cell is, and is likely always to remain, of the highest practical importance; the chapter dealing with it is consequently of great interest and value, as it contains in a convenient form most of the hitherto scattered information on this subject. The table of constants of standard cells shows that the results of recent determinations point to the value 1·433 volts being more nearly correct for the E.M.F. of a Clark cell at 15° C. than the generally accepted (and legal) value of 1·434 volts. The Helmholtz cell, recently modified by Hibbert, is of interest on account of its having an E.M.F. of 1 volt at 15° C. and also a very low temperature coefficient, though in this latter respect it is inferior to the cadmium cell. The final chapter, on the carbon-consuming cell, is, unfortunately, only a record of failures. It would seem as if commercial success, if ever to be achieved, will have to be sought on entirely new lines. But the problem is not likely to lose its fascination so long as the overall efficiency of steam generation remains as low as 6 per cent. whilst the primary battery holds out a prospect of the attainment of an efficiency of 73 per cent. or more.

M. S.

A MEMOIR ON MORAINES.

Geschichte der Moränenkunde. Von Dr. August Böhm Edlen von Bömersheim (*Abhandlungen der K. K. Geographischen Gesellschaft in Wien*, iii. Band, No. 4). Pp. viii+334; 4 plates, 2 figures in text. (Wien: R. Lechner, 1901.)

AS to the history of moraines, the author might fairly say "What there is to know, I know it." By patient research in libraries he has collected a great mass of information, of which the present volume is a summary. It also contains, besides the main subject, a

full account of drums or drumlins, which in some way or other are closely related to moraines, the proceedings of the Glacier Conference held at Gletsch in August, 1899, a section on the distinctions and nomenclature of moraines, a glossary and list of synonyms, and indices of authors and subjects. After answering, by quotations from writers, beginning with Sebastian Münster in 1544, the question, What is meant by a glacier? he passes on to moraines, which are at first mentioned casually, without any definite name. This does not appear till rather late in the eighteenth century, about the time of De Saussure. The word, no doubt of patois origin, was not admitted to dictionaries or encyclopedias till well on in the following century. According to Littré its origin is unknown, though it evidently is related to the Low Latin *morena*—bank of stones—which also appears in Italian under the older form, *mora*, and in Piedmontese *murena* designates earth piled in a bank by the side of a field. We also learn that in the German Alps the names *Ganda*, *Gandecken*, *Mârenes* and *Murren* are used, the last perhaps restricted to the Œtzthal district. Then follows a long series of abstracts or extracts chronologically arranged from the works of travellers by whom moraines have been noticed or described.

Before the first quarter of the nineteenth century the accounts become definite, von Charpentier in 1819 pointing out that some of the material in a terminal moraine travelled on, some under, the ice. The different varieties are clearly distinguished by F. J. Hugi in 1830, from which time the study assumes a scientific aspect, J. de Charpentier four years later clearly recognising old moraines. They began to be identified in other countries; C. Martins, in 1841, compared the glaciers of Spitzbergen and the Alps, and showed that moraines were also associated with the former. At the same time the study of everything associated with glaciers received a fresh impulse from the investigations of Agassiz, and from this date ground moraine (*grund moräne* or *moraine profonde*) begins to figure in books (though we believe he spoke only of *couche de boue*). Of this, perhaps, not so much is now heard as some quarter of a century ago, when a glacier might have assumed *Diruit*, *Ædificat* as a motto, for it was credited with scooping out a deep lake basin in one place and laying down a thick cushion of "till" in another. The most important additions to knowledge since the valuable summary in Dr. Heim's "Handbuch der Gletscherkunde" (1884) have been Prof. T. C. Chamberlin's observations, completed by his studies in Greenland, that in large glaciers an amount of material, greater than was generally supposed, is transported embedded in the ice (englacial), particularly in the lower part, in which, owing to shearing movements, it often assumes a rude stratification. Thus in certain circumstances, a very remarkable instance of which was described in 1898 by Profs. Garwood and Gregory, materials may even be carried uphill for a certain distance.

Students will find the twenty pages containing a summary of what has been written about drumlins or drums very useful for reference, though whether they will arrive at a clear conviction of how these were formed is less certain. That, however, is the fault of the subject, not of the author, for they are among the greatest puzzles in glacial geology. In America, in some districts of which they seem to be especially well developed, they form oval hills, occasionally as much as a mile in length, their breadth being about two-thirds of this, and they rise, according to their area, from 25 to 200 feet in height. They are composed of similar material to till, with slight or no signs of stratification, and when numerous show a rude parallelism. The principal facts in regard to their structure are generally admitted, but here unanimity ceases.

We owe a debt of gratitude to the author of this work. In such a subject, indeed in any one connected with glaciers, the task of searching through its literature is most laborious, and as the student often finds hypothetical inferences more abundant than careful descriptions of facts, he is tempted to doubt, as did the charity boy when he got to the end of the alphabet, "whether it was worth going through so much to get to so little." This book, with its summaries and useful indices, will enable him to ascertain what observations are on record and what hypotheses have been formulated. He will also find, in the account of the conference in 1899, the latest classifications proposed (in which, we think, over-minute distinctions are attempted), and will be enabled to begin personal investigations with a general knowledge of previous opinions, more than which is apt to be a hindrance rather than an advantage. T. G. B.

CHEMISTRY OF PAINTS.

The Chemistry of Pigments. By E. J. Parry and J. H. Coste. Pp. viii + 280. (London: Scott, Greenwood and Co., 1902.) Price 10*s*. 6*d*. net.

THIS book is divided into four parts or chapters. The first of these, occupying just seventeen pages, deals with the optical origin of colour; the second chapter, entitled the "Application of Pigments," discusses in separate sections their purely artistic uses, their decorative employment and their protective qualities. These sections are followed by descriptions of the methods of applying pigments, including pastel, water-colour, tempera, oil-painting, keramic painting, enamelling, glass and mosaic. Large use is made, in the first of these sections of chapter ii., of Russell and Abney's 1888 report on the "Action of Light on Water-Colours," and in the third section of Mr. Harry Smith's recent experiments on the protection against the rusting of iron afforded by many different kinds of paints. The two chapters which constitute the body of the work before us and occupy a couple of hundred pages are entitled respectively "Inorganic Pigments" and "Organic Pigments." Here we find much information of interest and importance in the actual analyses given of individual samples of different pigments and in the notes on methods of examining and testing pigments. But some pigments, such, for instance, as aureolin and cadmium yellow, are treated too summarily in view of their artistic importance, while to other pigments, notably to the large group of "coal-tar lakes," is assigned a treatment which they do not deserve.

And here the question forces itself upon a reviewer's attention, "For what class of readers has this book been written?" The authors speak in their preface of "those who are called upon to use or examine pigments

as a guide to the selection of those which are suitable." If students of art and painters are here meant, we fear that a large part of the information offered for their instruction will be thrown away, for none of them are likely to learn much from such statements as this (p. 258): "The basic colour auramine is imido-tetramethyl-diparadiamido-diphenylmethane." Perhaps, however, Messrs. Parry and Coste intended to address themselves to those who are to "examine pigments" rather than to those using them. If so, the work before us certainly presents, with the limitations of omission and inclusion previously indicated, a convenient compendium of figures and facts. A reasonable critic is averse to making much ado about misprints and mistakes that are akin to misprints, for he knows how provokingly these blots on his work elude the notice even of the really instructed author. But the pages before us seem to be in unusual need of correction. Take these examples: Fraunhofer (pp. 3 and 8) should not have an "e" before the "n," while the "o" ought to be without *umlaut*. It is surely a mistake to attribute to linseed oil a tendency to crack (p. 64). Viridian is the proper form, not vividian and veridian (p. 114). Hydrolised (p. 115) is incorrect. For arsenate (p. 157, line 31) read arsenite. The formula for gambogic acid, $C_{30}H_{35}O_6$ (p. 271), and that for euxanthic acid, $C_{19}H_{18}OH$ (p. 273), are alike impossible. The table of analyses of Indian yellow (p. 274) is incorrectly reproduced from Thorpe's Dictionary. On p. 231 globorus occurs as a specific name.

Quotations from Church's "Chemistry of Paints and Painting" are numerous, but are handsomely acknowledged.

OUR BOOK SHELF.

Handbook of Sanitation. By George M. Price, M.D. Pp. xi + 317. New York: John Wiley and Sons; London: Chapman and Hall, Ltd., 1901) Price 6*s*. 6*d*. net.

THE circle of those whose duties compel them to make a special study of sanitary questions is a rapidly widening one in the United States of America, as indeed it is in this country; and one gathers from the author's preface that in spite of the growing number of sanitary inspectors, the still greater number of candidates for inspectorships and the general interest in sanitary questions, there are in America no text-books in which the necessary knowledge is set forth in a concise and suitable form. Of course the sanitary laws and sanitary practice are different in the United States of America, or otherwise we could supply the deficiency from the somewhat extensive literature which exists upon the subject in this country. The general principles of sanitation apply to all countries, but the extent and nature of their application are often determined by legislation of varying character and scope. It is for that reason that many of the English text-books on sanitation are of limited use in America, and that the present volume will only appeal to a few English students.

In part i. of the work a *résumé* is given of sanitary science. The matter is often far too condensed; the important subject of water and water supply is, for instance, dismissed in about seven pages, and in this part, and this part only, there are one or two matters to which exception may be taken:—"Cretinism, as well as goitre, has been traced directly to a certain chemical composition of the soil" (p. 7); the contents of sewers are the breeding-places for various virulent bacteria . . . and constitute a favourable culture-medium for all other disease-causing organisms"; and in Fig. 22 a "washdown" W.C. is described as a "washout" form.

It is curious for us in this country, where iron house-drains are so rare, to read that the house-drain "should be hung on the cellar-wall or ceiling, unless this is impracticable, as when fixtures in the cellar discharge into it."

Part ii. is on sanitary practice. In this part are given the methods of application of sanitary science in various municipal departments, with extracts from the law, rules and regulations of New York and other municipalities. This constitutes the best part of the book, although here again certain matters (food, disinfection, &c.) are far too sketchily dealt with.

Part iii. of the book relates to the inspector, his duties and qualifications; and part iv. contains, besides useful chapters on sanitary law and sanitary organisation in the United States, extracts from model laws on various branches of sanitation.

Advanced Exercises in Practical Physics. By Prof. Arthur Schuster and Dr. C. H. Lees. Pp. x + 368. (Cambridge: University Press, 1901.) Price 8*s*.

IN this book the authors describe some seventy exercises in practical physics suitable for students preparing for a B.Sc. degree. The exercises, therefore, deal with elementary subjects, which are described at considerable length; for the authors attach "greater importance to neat and accurate work, properly recorded, than to the number of experiments which a student performs." The title "Advanced" is here used to mean that the work is to be done in a manner befitting an advanced student rather than that the subjects are illustrative of the higher parts of physics.

The contents of the work are divided into six books. The first book contains preliminary matters, amongst which appears the calibration of the spirit-level, which is generally omitted from text-books, although the instrument is one of frequent use. The second book is devoted to mechanics and general physics, and here we are glad to see twenty-four pages on the balance, for the experience of teachers is that students know, as a rule, very little about this important instrument. In the third book heat is the subject, and special stress is put on the proper study of the cooling corrections in calorimetric experiments. If the methods indicated here are carefully carried out, the student should obtain very satisfactory results in his heat measurements. The fourth book contains sound, and the fifth light. In the latter we have a very full discussion of the spectrometer. Polarisation is introduced in two exercises. The sixth book deals with magnetism and electricity.

It is refreshing to read this text-book, for it is not a mere compilation from others, and the teachers and students who use it will feel that they have a guide written by authors who have thoroughly and exhaustively considered the principles and methods of the experiments they are describing. One of the aims of a text-book must be to add to the convenience of the teacher and student in getting at the groundwork of a subject, and this is eminently done in the one before us. The clearness and logical order of the descriptions will greatly facilitate the student's work, and by its use, supplemented with experimental lectures, we think a wide knowledge of physics from the point of view of the facts will be obtained. The diagrams and illustrations are new and exceptionally well done, and the type and get-up of the book are excellent.

The work can be strongly recommended to teachers in schools as a reference book on practical physics, and to university students for general use in the laboratory.

S. S.

Recherches Expérimentales sur les Spectres d'Étincelles. By G. A. Hemsalech. In three parts. Pp. xvi + 135. (Paris: Libraire Scientifique, A. Hermann, 1901.)

THE author, as an introduction, gives a short historical notice of the investigations on the nature of spark spectra by Wollaston in 1802, Talbot and Wheatstone in 1836, and later those of Masson, Ångström, Kirchhoff, Miller, Huggins, Lockyer, Hartley and Adeney, Eder and Valenta, Exner and Haschek.

The first part of the book is then devoted to a short description of the characteristics of various types of spark, ordinary, intermittent and oscillatory, with the influence of varying self-induction on those of the latter description.

The second part describes in detail the apparatus, electrical and spectroscopic, used in the investigations, with illustrations of typical sparks of the three mentioned classes.

Part iii. is occupied by a series of tables showing the wave-lengths of the lines measured in the spectra of the fourteen metals, Fe, Mn, Ni, Co, Cd, Zn, Mg, Al, Sn, Pb, Bi, Sb, Cu, Ag, with their relative intensities under three degrees of self-induction. The lines in the spectrum of air are also tabulated, showing their varying intensity in the spectra produced by the above metals being used as poles.

The variation of the self-induction is accompanied by different results according to the metals used, and the fourteen elements investigated are divided into two groups, one containing Fe, Mn, Ni, Co, the other the remaining ten metals. With the first group, increase of self-induction produces a general increase of brightness of the constituent spectral lines, while in the second group the intensities of the lines are diminished by increasing the self-induction. The lines due to air may be completely eliminated.

The work, commenced by Schuster and Hemsalech conjointly, has been continued by the present author in the physical laboratory of the Faculty of Sciences of Paris at the Sorbonne. C. P. B.

Moral Nerve and the Error of Literary Verdicts. By Furneaux Jordan, F.R.C.S. Pp. xxiii + 141. (London: Kegan Paul, Trench, Trübner and Co., Ltd., 1901.) Price 3*s.* 6*d.* net.

THE aim of this little book is to throw some light on the effects in life and literature of two different points of view, the literary and the scientific. The first chapter lays down some "guiding truths" on mind and matter; mind is regarded as the function or action of nerve matter, just as contractility is the action of living muscle. All the manifestations of life—morals, religion, laws—are based on quantities, states and changes of nerve-matter. "Matter" is used as meaning natural stuff of which we have some knowledge. The second chapter expounds some "guiding truths" on moral nerve. Morality need not be defined; we know what it is. In men and animals the moral sense is predominant; in both, the impulse to do right is stronger than the capacity to think clearly; few men can measure the planets, but every man strives to preserve from danger the lives of his fellows. How came men and animals to be first of all moral? Because they possess moral nerve-matter; morality is nothing more than the action of moral grey-matter, and the moral apparatus came into existence because it is a factor essential to life. A material moral apparatus exists somewhere and somehow within the skull, and there are grounds for believing that moral nerve is more or less separate nerve, freely communicating with all other varieties of nerve, but characterised by greater simplicity and directness. The next two chapters are devoted to Mr. Spencer and Huxley as moralists. Mr. Spencer underestimates the potency of nerve-organisation, and is wrong in putting the origin of the moral sense quite late in the course of evolutional time, the truth being that a certain bed-rock code is found wherever life is found. In common with literary thinkers, he fails to see that creeds, philosophies and moral codes are not the producers, but the products of living human nerve. Huxley is judged by his Romanes address on "Evolution and Ethics," and the verdict is that the address is marked by not a little confusion, inconsistency and inaccuracy. The fifth chapter, on the principle of punishment, which concludes the first part of the book, introduces us to a fresh theory of the origin of morality; it now appears that the punishment of immorality is the one method by which morality originated. The chapter concludes with some interesting remarks on destructive anarchism and its remedies, but is marred by the grotesque suggestion that in order to effect a maximum of humiliation the assassin should, by way of punishment, be flogged by a woman!

Part ii., which occupies about half the book, deals mainly with the errors of literary verdicts, and if Mr. Spencer and Huxley fall short of the scientific ideal, we are not surprised that the student of nerve should find much to criticise in Tennyson, Mill, Carlyle, Emerson and Goldwin Smith. It is unnecessary to give an account of this part of the work; the author's point of view will be understood from our summary, given mainly in his own words, of part i. He has evidently read much, writes brightly, and has a fine enthusiasm for truth, but a fundamental error runs through the whole of his book; he assumes the existence of moral nerve, timid nerve, reasoning nerve, &c., and writes about them and reasons from them as if they were well-established realities like motor or sensory nerve, whereas, as a matter of fact, nothing is known about them. We should welcome any real contribution to our knowledge of the relations between the psychical and the physical aspects of thought, but the author gives us nothing of the kind, and in his crude doctrine of moral nerve, moral grey-matter and so forth he is merely playing with words.

Domestic Economy for Scholarship and Certificate Students. By Ethel R. Lush. Pp. vi + 251. (London: Macmillan and Co., Ltd., 1901.) Price 2*s.* 6*d.*

THE aim of the author of this small volume has been to provide for teachers a concise and clearly-written statement of domestic economy which shall cover the syllabus of the King's scholarship examination and the certificate examination of the Board of Education.

Domestic economy is a subject of wide range, comprising, not only the skilful management of domestic affairs and the wise expenditure of the income, but, in addition, the laws of health and the physiological principles underlying them, the management of the sick, and the intelligent treatment of ailments and accidents on general principles. The author is certainly to be congratulated on having attained her object in a most satisfactory manner. The matter is very clearly expressed, and great judgment and care have been exercised in the presentation of a difficult and complicated subject in order to maintain a suitable proportion in the treatment of the various branch-subjects comprised within the somewhat extensive scope of study of domestic hygiene.

The subject-matter is remarkably well dealt with in the short space at the author's disposal, and having regard to its variety, the teaching is exceptionally sound and correct. In a subsequent edition, however, the following facts should be taken into account:—

The illustrations of the starch grains on p. 7 are so poor as to be practically useless; the specific gravity of average cow's milk is not 1028 (p. 29); the determination of the melting point is of little value as a means of testing for margarine in butter samples (p. 37); and the most characteristic symptoms of enteric fever, consumption and small-pox are omitted, while those of other communicable diseases are given.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Huxley's Review of the "Vestiges of Creation."

IN the "Life and Letters" of Charles Darwin (vol. ii. p. 189), Mr. Huxley wrote:—"The only review I ever had qualms of conscience about, on the ground of needless savagery, is one I wrote on the *Vestiges*."

Can any of your readers inform me where Huxley's review of the "Vestiges of Creation" was published? I imagine it to have been written about 1853–54. FRANCIS DARWIN.

Botanical Laboratory, Cambridge, February 13.

Birds attacking Butterflies and Moths.

PROF. POULTON has asked me to recall any observations of my own of the attacks of birds upon butterflies. Unless one makes a note at the time of occurrence it is seldom one can recall to mind any particular instance of the kind, although it is not so rare as it appears; but of the two following instances I have still a vivid recollection. The first occurred during the beginning of August 1892, near Wokingham, Berks.: I was chasing a Clouded Yellow (*Colias edusa*, Fabr.), the first seen of the autumn brood, so that I was all the more eager to capture it, when much to my chagrin a Spotted Flycatcher (*Muscicapa grisola*) darted from a fence and caught it. The other observation was made during the summer of 1897 and deals with one of our common moths, which I am aware are more frequently attacked than butterflies. Whilst proceeding along the Cowley Road, Oxford, I saw a House Sparrow (*Passer domesticus*), making frantic efforts to capture a noctuid moth which seemed to be a Turnip Moth (*Agrotis segetum*, Schiff.). The peculiar way in which the moth seemed to roll over and over in the dusty road and the eagerness of the sparrow, together with the loud chirping which it kept up all the time, caused quite a small knot of spectators to assemble to watch the apparently unequal contest, and when at last the moth baffled its pursuer and flew away there was an audible murmur of applause.

22 Southfield Road, Oxford. A. H. HAMM.

HAVING seen some correspondence in the last two numbers of NATURE on birds attacking butterflies, I think the following may be of interest.

Early in June, 1900, when fishing at Belleek, co. Fermanagh, I noted on several evenings very heavy "hatches" of one of the larger sedge flies (*Phryganea sp.*), locally known as the wall-fly. On these evenings large numbers of gulls would come in from the coast, four miles distant, and steadily hawk up and down the river and neighbouring meadows, taking the fly eagerly. Subsequently, when the May fly was "up" on Lough Erne, it was common throughout the day to see flocks of gulls similarly employed, and this habit was so well known to many of the local gillies that it was no uncommon thing to fish first that part of the loch where the birds were busiest. A friend of mine—a good field naturalist—informs me that he has frequently seen sparrows, and on one occasion a greenfinch, catching butterflies which, so far as he remembers, were cabbage whites.

C. G. SELIGMANN.

St. Thomas's Hospital, February 14.

AS this subject is again interesting your readers, I would repeat that both my gardener and myself have independently observed robins capture and swallow the large cabbage white butterfly. HOWARD FOX.

Rosehill, Falmouth, February 18.

King Og's Bed.

I SEE that Mr. Wells, in his interesting discourse on "The Discovery of the Future," mentions "a sort of bed of King Og, to which all expressions must be lopped or stretched." We are told in Numbers that King Og had an iron bedstead, which was 9 cubits long and 4 cubits broad. But I cannot find that he put his bedstead to the use suggested by Mr. Wells. Is it possible that this gentlemen's memory is at fault, and that he is confusing King Og with the ancient Greek robber Procrustes, who was accustomed to torture his captives by stretching them if they were too short for his bed, and by lopping off portions of their legs if they were too long to fit the bed? T. B. S.

Edinburgh, February 10.

"T. B. S." is quite right. I regret very much that I did not verify my quotation. A confusion of Og's bed and the lopping propensities of Adoni-Bezek seems to have decayed to the likeness of Procrustes. I have lived in this error for years. I have often used the image of King Og's bed in conversation and, I think, in published matter. No one has ever detected my slip, and it is by no means impossible that I am the centre of propagation of a mistake that will turn up again. H. G. WELLS.

The Severn Bore.

DURING the past three years I have been observing the bore on the Severn, and have taken several measurements of the leading wave, or "head" as it is called here, as well as of the speed of the stream.

The river at Newnham being considerably wider than it is at Stonebench, where Dr. Vaughan Cornish made his observations, or at the Denny, where Mr. Whitmell was stationed, the phenomenon is not so remarkable—the speed is less and the height is lower.

Unluckily, since February 12, 1899, the heads for some reason or another have been comparatively low; none have since that date attained to 4 ft. 2 in., the height then measured. I was fortunate to obtain a photograph, which was published in the *Graphic* of February 18, 1899, but owing to the lack of light, for the best bores come up early in the morning, the plate was underexposed.

The popular idea of the height is greatly exaggerated; 6 ft. is stated to be not uncommon when a south-west wind is blowing, but during last September the maximum measured by me was 2·1 ft. and the speed 5·2 miles per hour (330 yards in 2 mins. 10 secs.).

Mr. Whitmell refers to the sound of the approaching bore being audible for some distance. It is a weird and grand sight during the moonlit September evenings to see the white line of foam advancing up the long stretch of river above Newnham, and the sound of the approaching mass of water is heard for more than a mile away, long before anything is to be seen.

Whatever may be the safety of a small boat on the upper reaches, it is not considered safe to be in a boat when the tide comes up here, and not many years ago two fishermen were upset with their boat and drowned below Awre.

The increase of speed above Newnham is always attributed to the narrowing of the stream and to the greater steepness of the banks, but neither here nor at the Denny have I ever seen anything approaching to seventeen miles per hour.

There is another phenomenon to be seen at Newnham which does not occur higher up, namely the formation of "racers," or series of waves caused by the flowing of the rapid current over the sandbanks. These "racers" occur in rhythmical order as the channel fills up, and at some few minutes after the head has passed, lasting only for a short time at any one spot, ceasing as soon as the water has reached a certain depth; they are violent in their action, and leave a record behind them in the shape of an alteration in the configuration of the sandbank over which they have surged and boiled whilst the water in midchannel rapidly but smoothly rises in level. E. W. PREVOST.

Newnham, February 15.

Squilla desmaresti.

SHORTLY after the publication of my note in the *Journal* of the Marine Biological Association, on the appearance of this stomatopod in the North Sea, I received a specimen from Mr. W. W. Dunlop, who informed me that it had been taken off Selsea Bill. Further inquiry resulted in my learning that it was taken "about the second week in April last year." Some three or four other specimens have lately been taken in the neighbourhood, where it was till now unknown.

It would be well to call attention to this fact soon, so that fishermen may try to find out if last year's appearance was extraordinary, or the result of better or luckier observation.

I may point out that an element in the case is the temperature of the water. F. JEFFREY BELL.

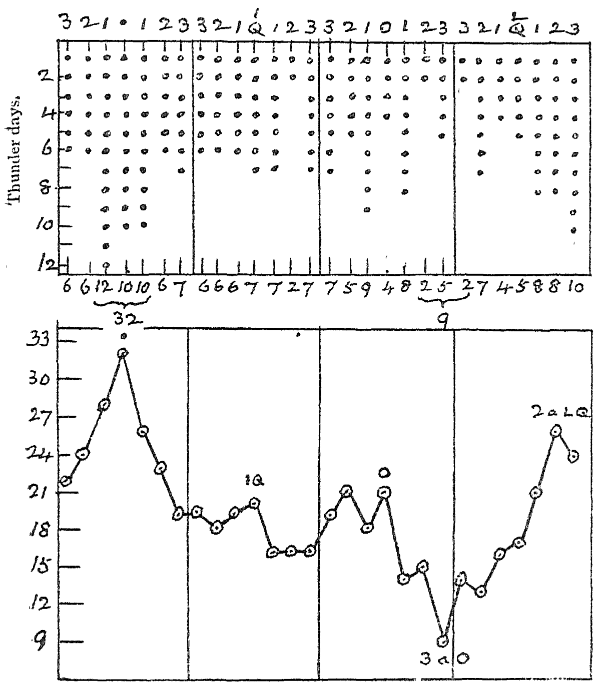
British Museum (Natural History)

The Moon and Thunderstorms.

IT is known that several meteorologists have affirmed a connection between thunderstorms and the lunar phases. In his recent admirable "Lehrbuch," Dr. Hann appears to favour this idea somewhat, and he gives some account of researches on the subject (p. 662).

I do not remember to have seen the Greenwich data treated from this point of view. It might, therefore, interest your readers to see how days on which thunder was heard at Greenwich in the last thirteen years (summer half) are distributed in the week about new moon, about first quarter, &c. This is shown in the diagram, where each dot represents one such day. The number of dots in each case is given below; and in the curve, each point represents the sum of three consecutive members of this series.

Lunar Quarters.



It will be seen that the extremes come about new moon (maximum) and about midway between full moon and last quarter (minimum). While the three-day group commencing with second after full moon had 9, that about new moon had 32—nearly four times as many.

This curve might be usefully compared with that, similarly obtained, for wet days (or days with 0·5 in. or more) at Greenwich, in twenty-four years (given in NATURE of August 29, 1901).

Arranging those 182 days by weeks and reckoning percentages, we have:—

	Week about New Moon.	1st Qr.	Full Moon.	4th Qr.
	57	41	40	44
Per cent. ...	31	23	22	24

The latter figures may be compared with those given in Hann's work for

	N. M.	1st Qr.	F. M.	4th Qr.
Kremsmünster (Wagner)	26·4	27·4	20·9	25·3
Aix la Chapelle (Polis) ...	26·9	27·5	21·5	24·1
Batavia (van d. Stok) ...	27·4	24·5	24 2	23·9

All agree in showing a larger percentage about new moon than about full moon, and in the two earlier phases than in the two later. The values for Kremsmünster and Aix are for much longer periods, and it is possible that a larger induction for Greenwich might bring out still closer agreement. The grouping by weeks, in the case of Greenwich, seems hardly to do justice to the contrast presented. It may be well, further, to remember that a 26-day period in thunderstorms, corresponding to the sun's rotation, has been affirmed.

Sidmouth, February 6. ALEX. B. MACDOWALL.

Progressive Variation in the Malayan Peacock-Pheasant.

IN looking over the specimens of this species (*Polyplectrum bicalcaratum*) in the Indian Museum, I have come across a most interesting skin of an adult male, showing variation in the direction of greater ornamentation. Normally, this peacock-pheasant has ocelli only on the wings and tail and the upper part of the back; but in the present specimen several of the black-speckled buff feathers of the back, immediately below the ocellated region, have clusters of the small spots richly glossed with green like the ocelli, the rest of the black speckling of the feather remaining normal. The green specks are always near the end of the feather, in the position occupied by the ocelli. Furthermore, this bird has the long under-tail-coverts decorated near the tip of the outer webs with a not very bright green-glossed ocellus, the inner webs merely showing black patches, such as are normal on both webs of these feathers in other specimens. Thus this individual presents on the upper surface a variation which might be advantageous in sexual selection, and beneath a similar enhancement of beauty which could hardly be of any use, since the Polyplectrons show off in an attitude which prevents any display of the under-tail-coverts. It is therefore interesting as showing how the beauty of a species might be enhanced both with and without the assistance of preferential mating on the part of the females.

The Inheritance of Mental Characters.

FURTHER discussion of this subject (*cf.* p. 245) should perhaps be postponed until the appearance of Prof. Pearson's detailed paper. Possibly, however, it may be permissible to discuss briefly Prof. Pearson's reply to my criticism.

(1) As to the possibility of proving the "soul" factor to be a reality, I would say that it may be possible some day to estimate very exactly the value of the other two factors (heredity and environment), and it will be significant if there is then found to be a residuum not accounted for. This line of reasoning is not new; compare A. R. Wallace, "Darwinism," chap. xv.

(2) It seems to me very likely that the correlation between the mental characters of brothers would be less than between the physical, if only the factor of heredity were considered. It does not follow from this that the mental characters are less inherited, taking the race as a whole, but only that they are less evenly inherited, so that the true measure of inheritance could only be determined by studying a number of successive generations. I tried to set this forth in the paragraph which Prof. Pearson says he cannot understand.

(3) There are, however, other disturbing influences. Even at birth, we must believe that we have not the simple product of heredity, as has been well explained lately by Prof. Ewart (*Sci. Trans.* Roy. Dublin Soc., October 1901, p. 366). Again, the several faculties do not mature at the same age, so that statistics based on children "in public schools, high schools, secondary and primary schools of all classes" cannot be strictly comparable, nor does it seem possible, in the case of mental traits, to make definite allowance for age, as can be done with more or less accuracy in the case of physical characters.

East Las Vegas, New Mexico, U.S.A., February 1.

ICELAND.[1]

FEW parts of the earth's surface possess so strange a fascination, at once attractive and repellent, as that large island which, away to the north-west of Europe, stands between the Atlantic and the Arctic Ocean. Its language and literature, its connection with the northern mythology, the antiquity and continuity of its annals, and its quaint customs and traditions have given it a special place in the history of nations. The strange aspect of its surface and climate—the home of frost and fire, the scene of some of the most colossal volcanic eruptions which man has ever witnessed, the site of vast snow-fields and glaciers, a region shaken with earthquakes, devastated by

1 "Geological Map of Iceland." By Th. Thoroddsen. Surveyed in the years 1881–1898. Edited by the Carlsberg Fund. (Copenhagen, 1901.)

appalling floods, swept by Atlantic storms and sometimes chilled by Greenland icebergs—these and other impressive features have made Iceland a region of peculiar interest to students of nature. To the geologist, in particular, the country offers a wide field for observation. Its ice-fields remain as relics of the Ice Age, and are still large enough to illustrate many of the characteristics of that period in geological history. Its volcanoes display almost every type of volcanic action, and present a marvellously extended chronicle, stretching back from the present day through the Glacial period into older Tertiary time. The vicissitudes of its climate and the general absence of a protecting cover of vegetation afford singular opportunities for the study of the progress and rate of denudation, while its many hundreds of miles of coast-line furnish inexhaustible materials for investigating the action of the sea on the shores, and the causes which lead to the advance or retreat of the land.

That Iceland has been much less visited than such an interesting region might have been expected to be has probably arisen mainly from two causes. In the first place, it lies a good way off, across a stormy ocean on which the means of communication are neither so frequent nor so luxurious as modern requirements demand, and, in the next place, when the traveller reaches the island, he finds that to journey through it involves, not only a good deal of expense, but exposes him to privations which he is not always well able to endure. Many who have shrunk from the voyage in face of these difficulties have longed for what comes next in value after an actual personal visit to a country—a good map of it, on a sufficiently large scale and with enough of detail to allow its main characters to be intelligently grasped. Geologists will be glad to hear that this want has now been supplied. They are well aware that for some twenty years the indefatigable Icelandic geologist Dr. Th. Thoroddsen has been at work, summer after summer, mapping his native island and publishing from time to time short notices of his investigations. Only a few of these notices have appeared in English journals; more have been translated into German, but the fullest and best accounts of his work are those in Danish, and more especially the series of papers in the *Geografisk Tidskrift* published at Copenhagen from 1884 up to the present time. Maps of various portions of Iceland, which have accompanied some of these papers, have shown with what skill and energy their author was carrying on his self-imposed task, in the midst of all the known difficulties of Icelandic travel. The work on which he has been engaged was rather the duty of a Government than what can be expected to be undertaken by a private individual. But he has stuck to it with courage until his materials have grown ample enough to permit him to embody them in a general map of the whole of the island.

This map is now issued in two sheets, printed in colours and published at Copenhagen, with the help of the Carlsberg Fund. It is on the scale of 1-600,000, or about ten English miles to an inch, which is large enough to show much detail that has never yet been expressed on a single map and summarised in so clear and intelligible a manner. The title and explanations of signs and colours are given in English. The map presents a more striking picture of the geology and physical geography of the island than has ever been before available, and contains a vast fund of instructive information in regard to matters not only of local, but of theoretic interest.

One of the first features to catch the observer's eye, as he glances at the distribution of the colours, is the wide area occupied by the Tertiary basaltic plateau. This vast underlying platform, on which all the later volcanic manifestations have been displayed, still forms the surface of most of the western, northern and eastern districts. Its nearly horizontal sheets of dark brown rock have been cut into innumerable fjords and inlets on the coast, above which they rise in long lines of mural precipice. Among the basalts lie layers of terrestrial vegetation, the famous lignites or "Surtarbrandur," the positions of which, where known, are indicated on the map. The plateau is diversified by the uprise of numerous masses of liparite and granophyre, which are especially developed in the eastern part of the island. They may be compared with the granophyre intrusions which have disrupted our own Tertiary volcanic plateau in the west of Scotland. A further coincidence between the volcanic geology of the two regions is to be seen in the scattered patches of gabbro shown on the map, though this rock does not appear to play the important part in Iceland which it does among our Western Isles. For the first time some adequate conception can be formed from this map of the extent and distribution of the palagonitic tuffs, breccias and conglomerates, for which Iceland has so long been noted.

The post-Tertiary eruptions have broken out along a broad belt of ground which crosses the island from south-west to north-east. Dr. Thoroddsen separates the "doleritic lavas" as a pre-Glacial and Glacial series from the "post-Glacial basaltic lava" and the "post-Glacial liparitic lava." Of the area and distribution of the huge floods of basalt, which have transformed so many hundreds of square miles of the interior of Iceland into black waterless and verdureless deserts, we can now form a clear idea. The vast expanse of the Odádahraun, which has been the scene of the most colossal outpouring of molten material, can be seen in its true proportions. We can realise, too, the source and extent of the great eruption from Laki in the year 1783, which has been made so familiar by the imperfect and incorrect notices of it handed down in text-books.

By a series of simple signs Dr. Thoroddsen has succeeded in separately indicating the positions of the great lava-domes, comparable with those of Hawaii, such as the massive Trölladyngja and others on the plateau of Odádahraun; of the volcanoes of Vesuvian type, built up of lavas and tuffs round a central orifice, like Hekla; and of the crater-rows, like that of Laki. The map shows clearly the important place which this third type takes in the vulcanism of the country. A further separation is made of the "glacial volcanoes" from those which are "glacial and recent." The positions of solfataras, hot springs and mineral springs are marked, and space is found for lines showing the trend of raised beaches and the highest ascertained limit of submergence.

Nor are the superficial formations omitted; the various Drift deposits of the uplands are represented by one tint and those of the lowlands and valleys by another, while on the south coast, the wide stretches of sand and mud, discharged by the hundreds of streams that descend from the great snow-fields and glaciers of the Vatnajökull and the western Skaptafells district, are distinguished from the other recent accumulations. An interesting feature of the map will be found in the arrows that mark the direction of the ice-striæ on the rocks. These signs indicate that while the general movement of the ice-sheet has been outwards on all sides, each separate mass of high ground has exercised an influence in guiding the ice-drainage. This local effect is well brought out in the north-western peninsula, where the striæ descend into the fjords on either side of the main watershed. The Glámu Jökull, which still caps that portion of the basaltic plateau, is thus the lineal descendant of the ice-fields that once spread over the whole island.

In comparing the coast-line of different parts of the island as depicted on this map, the geologist cannot fail to be struck with the contrast between that of the southern district and that of the rest. From Reykjavik right round the western, northern and eastern sides of Iceland, where the ancient Tertiary basalt-plateau meets

the sea, the shores are deeply indented with innumerable fjords and little inlets, above which the rocks rise in long lines of terraced cliff. Along the southern coast, the margin of the land consists for the most part of low flats and bars of fine sand and mud, brought down by the many rivers and streamlets that escape from the edges of the great glaciers and snow-fields. A contest is constantly waged between the Atlantic breakers, on the one hand, and the sediment-bearing inland waters, on the other. Bars and spits are thus thrown up, behind which stretch long narrow lagoons. For a distance of some 250 English miles such is the general character of the coast-line. In spite of the fury of the Atlantic storms and the occasional breaking down of the detrital barriers opposed to them, the sea has been losing ground. Since the Ice Age so much sand and silt have been carried down that a wide stretch of lowland has been gained, and the sea has become so shallow that for long distances no ship of any size can approach the coast. Yet such is the unfortunate physical geography of Iceland that, at least in the meantime, this accession of land brings but little advantage to the inhabitants. The territory is so liable to rapid inundation, and to be swept over by sudden floods, that it is too dangerous to be reclaimed, and often cannot even be crossed without serious risk. In that portion of it which lies nearest to the Mýrdal glaciers, an additional source of peril is furnished by the eruptions of Katla, which, buried under the snow-fields, from time to time finds a vent, disrupts and melts the ice, and sends it in huge masses down the floods that sweep over the plain and carry their freight of ice even out to sea. Dr. Thoroddsen has given in his various publications graphic though only too brief accounts of these operations, and his new map enables us to follow their scope with greater clearness.

Now that the great labour of preparing this map has been successfully accomplished, every geologist and every visitor to Iceland will hope that Dr. Thoroddsen may be able to devote himself to the preparation of a full description of his native country. He has accumulated a large amount of material, only a small part of which has been published, and this merely in brief outline. He has, doubtless, many parts of the island to revisit and many difficult questions to elucidate before such a volume or series of volumes can be written. We can only wish him continued health and strength for his important task. It is surely not too much to hope that work of so national a character and of so much general scientific interest will meet with such hearty support and aid in Denmark that it may be vigorously prosecuted to an early and successful conclusion. ARCH. GEIKIE.

NATURE STUDY IN SCHOOLS.[1]

WE have received the first part of the *Nature-Study Journal*, published by the South-Eastern Agricultural College, Wye, Kent, with a preface by Sir William Hart-Dyke and an introduction by the editor, Mr. A. D. Hall, principal of the College. This new publication is the outcome of a discussion held at the College during a summer course for teachers in 1901, and the thirty-one teachers, mostly from schools in Kent and Surrey, whose names are appended to the part received constitute the first members of a Nature-Study Society by which this journal will be maintained. The object of the journal, as set forth in the preface and introduction, is mainly to facilitate the teaching of "nature-knowledge" in rural schools, by enabling the teachers to interchange ideas and schemes of instruction and to be in communication with the Wye College as a central organisation. The whole subject of nature-teaching in rural schools has been brought into prominence of late years, and there has been a distinct revival in this branch of education to which we have, from time to time, called attention in these columns. The initiatory work of the Countess of Warwick in emphasising by practical example the necessity for the establishment of schools of science in rural districts (see article by Lady Warwick and Prof. Meldola, NATURE, vol. lix. p. 7), followed by the work of the Agricultural Education Committee inspired by Sir William Hart-Dyke and Mr. Henry Hobhouse, has been largely instrumental in bringing about this much-needed reform, and the demand for sound instruction in this kind of science has naturally been on the increase since the issue of the "Specimen Courses of Object Lessons, &c." by the Board of Education (NATURE, vol. lxiii. p. 603). It is to be hoped and expected that this demand will go on increasing, and the establishment of the present journal is therefore opportune. The great danger to education in this country is complete apathy and neglect in the first place, and then reckless precipitation and unorganised excess in order to try to recover lost ground. Rural education is bound to go through the usual phases, and we may already begin to ask ourselves whether there is anything to be gained by the multiplication of organisations, conferences and congresses, all carrying on much the same work and frequently overlapping in functions.

The Nature-Study Society has, however, in favour of its creation the circumstance that it is composed of teachers who are engaged in giving actual instruction in this subject in schools, and the journal is to be largely devoted to the publication of specimen lessons. Two such lessons are in the part before us, one on "Leaves and their Veining" by Mr. H. Brooker, of the Ewhurst National School, and the other by Mr. A. E. Chandler, of Puttenham, on "Dodges of Nature." The first point that cannot fail to strike the reader of these two lessons is their extraordinary divergence in standard. The collecting and classification of leaves according to their veining is a lesson in pure observation. The "dodges" referred to in Mr. Chandler's lesson are the contrivances for cross-fertilisation in long and short-styled primroses and in Salvia, and the pupil is afterwards told to collect some flowers of Arum, to study the inflorescence, and then to work out for himself the mechanism of fertilisation by the aid of hints given in the following form:—"What can be the work of the little hairs that nearly close the opening of some of the hoods? Do you notice any insects? Did you ever think out the design of an eel-trap or a lobster-pot?" It is obvious that these two lessons must appeal to pupils of different ages and acquirements. The new Society and its journal should have a useful career if only by enabling teachers to compare schemes, as in the two lessons noticed. Such specimens bring out very clearly the necessity for graded and connected series of lessons leading from simple observation and description up to observation combined with inductive reasoning. The introduction of nature study into rural schools cannot but be productive of good, and although, as the editor points out, it is not primarily directed to keeping children on the land, it may have this effect indirectly by leading children "to see that a country life has its own interests and is not merely stupid routine; particularly we want the children who do stay in the country to have laid a foundation of thinking about rural pursuits which can be built upon later." The Society will welcome as new members all teachers who are conducting nature-study classes, the only obligation being that the member shall be expected to send a specimen lesson for publication. The Society is worthy of support, and we commend it to the notice of teachers who are already holding, or who desire to conduct, classes in this subject, which is one that by proper handling can be made really fascinating to children of every degree of intelligence.

A DOUBTFUL DEVELOPMENT OF LOCOMOTIVE ENGINEERING.

UNDER the heading of "A New Development of Economical Railway Haulage," the *Times* of February 13 tells us that "we are on the eve of a mechanical revolution such as has never been seen since the introduction of steam," and enters in a general way into a statement of results said to have been obtained from an old Great Northern locomotive fitted with a new type of valve-gear, the use of which is said to reduce the consumption of coal nearly 50 per cent. and increase the hauling capacity of the engine considerably, when compared with a sister engine fitted with the ordinary gear and doing similar work.

Locomotive engineers are becoming accustomed to the rapid advances of electrical science, and seldom doubt what the electrical engineer may claim to have achieved; but with the locomotive things are different; the machine is not new, neither is the valve-gear; the coal consumption has been thoroughly tested and the various gears examined from every point of view, there being no particular variation of opinion as to the most beneficial distribution of steam in the cylinders.

For this reason it is extremely startling to be told that a modified valve-gear will reduce the fuel bill nearly 50 per cent. with an increased load, the boiler pressure being only 140 lbs. per square inch, considerably below the average working pressure of to-day.

The locomotive experimented upon was built in 1882, and was, therefore, of the late Mr. P. Stirling's design, a type of locomotive famous for having a very small boiler in proportion to the cylinder dimensions, and, therefore, one requiring to be forced to keep up the steam, the forcing being done by a very keen draught induced by a small blast-pipe; such engines are famous for throwing fire from the chimney-tops. Yet, besides claiming this abnormal economy, we are told that the exhaust is so soft that the question of fire-throwing is entirely got over and that spark arrestors may be considered things of the past—surely a wonderful result.

The article referred to fills a whole column of the *Times*, but we may be allowed to doubt the results given, for although the name of Mr. H. A. Ivatt, the locomotive engineer of the Great Northern Railway, is quoted more than once, the statements do not appear over his name, and until they do, locomotive engineers may be excused if they continue to hold adverse opinions. The economical working of the locomotive is no new study; it is in the hands of able men who, no doubt, would be highly delighted if they could clearly demonstrate a saving of 5 per cent. even over previous practice.

N. J. L.

NOTES.

SIR WILLIAM ROBERTS-AUSTEN, K.C.B., F.R.S., will deliver the tenth "James Forrest" lecture, on "Metallurgy in Relation to Engineering," at the Institution of Civil Engineers on Wednesday, April 23, the date having been unavoidably altered from that originally proposed.

ARRANGEMENTS have now been made for Major Ronald Ross, Walter Myers lecturer in the Liverpool School of Tropical Medicine, to proceed for the third time to Freetown, Sierra Leone, on the work of the School. The expedition which he will rejoin is the fifth organised by the School, and went out early last year under Major Ross himself with Dr. Logan Taylor.

THE International Congress on the Methods of Testing Materials, held in 1900, decided to offer a prize of 3500 francs to the author who has made the most important contributions to the subjects for the advance of which the Congress was organised. The adjudication of the award of this prize has just been placed in the hands of the Comite des Arts Mécaniques of the Paris Société d'Encouragement.

ARCHÆOLOGISTS and other students of antiquities will be glad to learn that it is proposed to obtain for Magdalene College, Cambridge, a copy of the head of Mr. F. C. Penrose, F.R.S., honorary fellow of the College, from the portrait painted by Mr. Sargent, R.A., for the Royal Institute of British Architects. The portrait will be presented to the College in recognition of Mr. Penrose's valuable services both to science and art. Among the supporters of the proposal are Dr. J. W. L. Glaisher, F.R.S., Sir R. C. Jebb, Prof. Liveing, F.R.S., Sir J. Norman Lockyer, K.C.B., F.R.S., Mr. A. G. Peskett and Lord Thring, K.C.B. Subscriptions are invited and should be sent (crossed Barclay and Co., Cambridge) to Prof. A. Newton, F.R.S., Magdalene College, Cambridge.

THE president of the Royal Geographical Society has made a special appeal to the fellows of the Society on behalf of the relief ship which must start not later than July next to obtain news of the *Discovery* and render assistance if necessary. It appears from the circular issued by the president that only 150 of the 4000 fellows of the Society have yet contributed to the funds for the relief ship. The council has, however, made itself responsible for the ship, which is now lying in the Thames and will shortly require to be furnished with stores and equipped with officers and crew. A spirit of loyalty should induce fellows of the Royal Geographical Society to provide the funds which will relieve the council of anxiety and ensure that essential precautions are taken for the safety of the members of the National Antarctic Expedition.

THE annual meeting of the Society for the Protection of Birds will be held on Wednesday, February 26, at the Westminster Palace Hotel, Victoria Street, London, S.W. The chair will be taken at 3 p.m. by Sir George W. Kekewich, K.C.B., secretary to the Board of Education. A proposal to establish a Bird and Arbor Day throughout the British Isles will be considered.

ON Tuesday next, February 25, Mr. W. N. Shaw, F.R.S., will begin a course of two lectures at the Royal Institution on "The Temperature of the Atmosphere, its Changes and their Causes." The Friday evening discourse on February 28 will be delivered by Prof. H. A. Miers, F.R.S., his subject being "Gold Mining in Klondyke," and on March 7 Prof. H. Becquerel, Membre de l'Institut, Paris, will deliver a discourse (in French) on "Radioactive Bodies."

A DISASTROUS earthquake occurred in Transcaucasia on February 13. Shemakha, the principal town in the area affected, has been completely laid in ruins, more than 20,000 people having been rendered homeless and 2000 lives lost. The first shock was felt about midday on February 13, and in a few seconds the Orthodox church, the mosques, the public buildings and hundreds of houses had fallen. The shocks were felt over a very wide area, and continued to recur during several days. A writer in the *Evening Standard* points out that in such a region as that affected the shocks may continue for a long time. To the north rises the great chain of the Caucasus, a region of crystalline and sedimentary rocks bent into great folds, not less remarkable than those in the Alps. In such a locality earth-tremors are at any time possible. In the latter chain no trace can be found of an extinct volcano, but Elbruz, the highest summit in the Caucasus, and Kasbek, which easily overtops Mont Blanc, are both ruined volcanic cones. Many more, though on a much smaller scale, are scattered over the region south of the Caucasus. In fact, signs of volcanic action are abundant over a very large part of the great upland plateau south of the Caucasus—the region where Turkey, Russia and Persia meet.

Ararat itself, though its crater has vanished, is an extinct volcano, for its rocks, where they disappear beneath the summit snows, are merely scoria. Some others, however, still retain their craters in a more or less perfect condition. A renewal of earthquakes and of volcanic eruptions, therefore, is not surprising. All the south of the Caucasus has occasionally suffered in this way. The neighbourhood of Ararat was severely visited in 1840; there was a bad earthquake in Asia Minor fifteen years later, and shocks are not infrequent in various parts of the region between the Black and Caspian Seas, the Eastern Mediterranean and the valley of the Euphrates.

PROF. E. C. PICKERING has completed twenty-five years of service as director of the Harvard College Observatory; and we learn from *Science* that in recognition of this fact the staff of the Observatory has presented him with a silver cup.

MR. HARRY F. WITHERBY is about to leave England on a new ornithological expedition to Persia. It is Mr. Witherby's intention to penetrate the mountainous region north-west of Shiraz, after working the area between that town and Bushire.

THE seventieth annual meeting of the British Medical Association will be held at Manchester on July 29, 31 and August 1. The president is Dr. G. B. Ferguson and the president-elect Mr. W. Whitehead. An address in medicine will be delivered by Sir Thomas Barlow, Bart., K.C.V.O., and an address in obstetrics by Prof. W. J. Sinclair. The scientific business of the meeting will be conducted in seventeen sections, which, with their presidents, are as follows:—Medicine, Dr. J. Dreschfeld; surgery, Mr. J. Hardie; obstetrics and gynæcology, Dr. D. L. Roberts; public medicine, Dr. J. Niven; psychological medicine, Mr. G. W. Mould; physiology and anatomy, Prof. Wm. Stirling; pathology, Prof. Sheridan Delépine; ophthalmology, Dr. David Little; diseases of children, Dr. H. Ashby; laryngology, Dr. A. Hodgkinson; otológy, Dr. W. Milligan; navy, army and ambulance, Brigade-Surgeon-Lieutenant-Colonel G. S. Elliston; dermatology, Dr. H. A. G. Brooke; pharmacology, Dr. N. I. C. Tirard; ethics, Dr. S. Woodcock; industrial hygiene and diseases of occupation, Dr. A. Whitelegge; tropical diseases, Sir W. R. Kynsey, C.M.G.

A SPECIAL committee of the Franklin Institute, Philadelphia, has reported in favour of the adoption of the metric system of weights and measures in the United States. The National Government is urged to enact such laws as will ensure the adoption of the system in its various departments, as rapidly as may be consistent with the public service. A number of questions have been discussed by the committee, and definite answers agreed upon. Thus, the opinion is expressed that no valid objection has been effectively urged against the metric system except that the numerator cannot be divided by two. A similar objection could, of course, be applied to the decimal system of currency in use in the United States. For convenient small units of everyday measurement, the millimetre is held to be better than either 1/16 inch or 1/32 inch, the latter being rather a fine subdivision for ordinary rough measurements. If the National Government can be induced to adopt the system in all its departments, it is believed that the adoption of metric measures throughout the country would follow within a reasonable time.

AT the Imperial Institute on Monday, Dr. C. F. Harford-Battersby, principal of Livingstone College, gave a lecture on "The Obstacles to Development in West Africa." After referring to some of the minor impediments to West African development, a description was given of the discoveries which have recently been made with reference to the malaria question. It is now admitted by all malarial specialists that the mosquito is the means of communicating this, and some other diseases, to man. In this connection reference was made to Major Ross and also to Dr. Manson, under whose leadership the London School of Tropical Medicine has done such useful work, both in educating a large number of medical practitioners proceeding to different tropical climates and in various expeditions for investigating the subject of tropical disease. The Liverpool School of Tropical Medicine has also conducted a series of investigations into the subject of malaria on the west coast of Africa, and is now engaged in carrying through important sanitary operations besides education work in this country. Dr. Harford-Battersby referred to the instruction that is being given at Livingstone College to missionaries in questions of tropical hygiene and to the facilities afforded by the Travellers' Health Bureau, mainly by means of the quarterly journal *Climate*, to those who might desire information with regard to what precautions should be taken in entering a tropical climate. In conclusion, he hoped that the Governments of the different Colonies would take up in real earnest the sanitary measures necessary to carry into practical effect the important discoveries which have been made by scientific experts, and that the public generally would recognise the necessity of acting upon the recommendations which have been made as to protection from mosquitoes and would cooperate in carrying through adequate sanitary reforms.

WE have received the *Annales* of the Magnetic Observatory of Copenhagen for 1897-8, of which Dr. A. Paulsen is director. The observatory is to be congratulated as being one of the very few institutions that publish magnetic observations in detail. The present volume contains hourly values of declination and horizontal force, and in addition the hourly and daily means have been computed, and the absolute extreme values are stated for each day.

DURING the past week most parts of this country have experienced severe night frosts. In the neighbourhood of London the thermometer has fallen as low as 14° in the screen, and 7° on the ground. In the midlands the readings have been considerably lower, and the exposed thermometer fell below zero. The temperature during February has not been so low since 1856, with the exception of three days in February 1895. The day temperatures have been low in most parts of the kingdom. On Sunday, with a maximum shade temperature of 35°, the solar radiation thermometer rose to 80° at Greenwich.

THE Report of the Meteorological Council for the year ending March 31, 1901, has just been presented to Parliament. The Council has been reconstituted and now consists of five of the original members, who act as directors; these receive remuneration for their services. Five additional members have also been appointed by the Royal Society, among whom we are glad to see the name of Dr. R. H. Scott, who has been so intimately connected with the Office since its transference from the Board of Trade in 1867. Mr. Francis Galton, whose work was especially noteworthy in connection with the improvement of meteorological instruments and methods, and who first suggested the term "anti-cyclone," now so commonly used, has retired from the management on account of age. The superintendence of the supply of meteorological instruments for the use of the National Antarctic Expedition was undertaken by the Council, and after consultation with Sir G. G. Stokes, the Campbell-Stokes sunshine recorder was remodelled, to register during the twenty-four hours. Among the more important operations of the Council may be mentioned the arrangements for the investigation of the London fog, in cooperation with the London County Council, the establishment of observations at 7h. a.m. in connection with the German and Dutch Meteorological Offices, for the improvement of the telegraphic weather service,

and the preparation of monthly pilot charts of the north Atlantic and Mediterranean, which have been frequently noticed in our columns. Arrangements have also been made, at the request of the United States Weather Bureau, for sending daily weather telegrams to Washington. The percentage of complete and partial success of the weather forecasts reached eighty-four, which is higher than that for any year during the last decade, except 1893, when the same high figure was attained. The success of storm-warning telegrams was 92 per cent.

A PAPER on wireless telegraphy is given by Prof. F. Braun, of Strassburg, in the *Physikalische Zeitschrift*, iii. No. 7. Without going into elaborate details as to the transmitter and receiver, it may be mentioned that the problem of resonance received careful attention in the construction of these apparatus, the desirable conditions being that waves of a certain frequency alone should be transmitted and received and that the receiver should be as sensitive as possible to these particular waves. The experiments were commenced by Prof. Braun at Strassburg in 1898; in 1899 they were continued at the mouth of the Elbe. Communication was set up between Cuxhaven and a lightship distant thirty-four kilometres. Later, messages were transmitted between Cuxhaven and Heligoland at a distance of sixty-five kilometres. It was thought possible that by means of an acoustical instead of a writing receiver, the distance from which messages could be received could be increased two and a half to three times.

IN connection with the campaign against hailstorms, Prof. V. Monti publishes in the *Bulletin* of the Italian Meteorological Office some statistics of the number of storms accompanied by snow at different stations, as recorded for the period 1881–1887 inclusive. The phenomenon of snow during thunderstorms is shown to be very rare in Italy, and in about one-fourth of the storms in which snow fell it was also accompanied by hail. When account is taken of the time of year as well as of the altitude of the station, it is found that in the majority of cases snowy thunderstorms occurred when snowy weather was the normal condition of affairs. There are but few records of snow falling out of season as a result of the sudden cold produced by thunderstorms. These statistics, so far as they go, are interesting as affecting the theory that by bombarding a thunderstorm the hail is transformed into snow. If snow frequently falls after a storm-cloud has been bombarded, and rarely under other circumstances, the theory in question obtains support. But, as Prof. Monti points out, we have not at present sufficiently complete statistics to enable any very definite conclusions to be drawn.

JUDGING from the capital figures which illustrate an article by "S" in *Globus* (Bd lxxxi. p. 58) on the perforated landscapes of Kappadocia, that country must present a most remarkable appearance. In the district of the ancient Cæsarea-Mazaca, a plateau composed of a bed of tuff is topped by a layer of lava; denudation has resulted in broad cañon-like valleys, from the flat floors of which arise innumerable pointed sugarloaf shaped pinnacles. Many of these have been pierced and tunnelled for dwellings for ages past, and the caves are still being made. Some of the caves were used for religious purposes, and we have ruins of temples and of Byzantine churches carved out of the solid rock.

THE current number of *Man* contains several interesting papers. Prof. Flinders Petrie gives a plate illustrating two dozen hitherto unpublished prehistoric Egyptian figures of men and animals. The Rev. R. A. Gatty describes his finds of pigmy flints from Lincolnshire; perfectly similar flints have been found in various other localities in England, as well as in Belgium, in France, and in India. These problematical implements are of very delicate workmanship, but more information is required before any definite statements can be made as to their use or their users. Mr. Gatty believes that they were actually made at Scunthorpe in Lincolnshire from flint river pebbles.

DR. WALTER E. ROTH, the Northern Protector of Aboriginals, Queensland, has recently published his third *Bulletin* on North Queensland ethnography. The subject is "Food: its Search, Capture and Preparation," and there is no need to say more than that the facts are presented with that fulness of knowledge and concise detail that characterise all Dr. Roth's writings. As an example of this thoroughness it may be mentioned that Dr. Roth refers to some 240 plants which are used as food in some form or another, the scientific name of each plant being given. In addition to these, the natives know of twenty-two plants which they use to stupefy or poison fish. The plates illustrate the various kinds of baskets, nets, snares, &c. used by the North Queensland blacks. The only fault we have to find with this very valuable paper is its shape, but being a Government Report it is probably unavoidable that it is printed of Blue-book shape; this must be put down to the official mind and not to Dr. Roth. The *Bulletin* is marked C.A. 81—1901, Home Secretary's Department, Brisbane.

THE principal article in *Nature Notes* for February is one on the enemies of trout, by Mr. E. T. Daubeny.

IN the February number of the *Irish Naturalist*, Messrs. Mellard Reade and J. Wright describe the occurrence of marine boulder-clay in county Cork, with a list of the contained Foraminifera.

OWING to the roughness of the passage, which has to be made in an open boat, visitors to the little island of Bardsey, lying off the extremity of Caernarvon, are few and far between, and it is therefore a favourite resort for birds of many species. A list of the species met with during a visit to the island in May of last year is given by Mr. O. V. Aplin in this month's *Zoologist*.

THE history of the gradual diminution of the habitat in Britain of the swallow-tailed butterfly appears in the February number of the *Entomologist's Monthly Magazine*. At the present day this fine species is met with only in Wicken Fen and Ranworth and certain other Broads in Norfolk. Formerly, however, according to the author, Mr. C. W. Dale, it occurred in no less than fifteen other English and Welsh counties.

TO the February issue of the *Entomologist*, Mr. W. J. Lucas contributes an account of the dragon-flies taken in Britain during the past year. Very interesting is the occurrence in Hampshire of the form known as *Oxygastra curtisi*, which has not been observed in Britain since 1882, when four specimens were taken at the same place. The author hazards some suggestions as to the breeding place of this rare insect in Hampshire.

IN a recent issue of the *British Bee Journal*, Mr. F. W. L. Sladen raises the question whether bees can hear. The author claims to have discovered that the so-called Nassanoff's organ—the membrane between the fifth and sixth dorsal segments of the workers—is really a scent-producing organ, and that this scent forms a means of communication between bees. He further suggests that bees have cognisance only of the well-known "hum," and do not recognise ordinary sounds.

THE second number of *The Emu* fully bears out the promise of its predecessor, and is illustrated by some excellent reproductions of photographs of Australian birds' nests. Perhaps the most generally interesting and important article is one by Mr. D. le Souëf, on protective coloration in Australian birds and

their nests, which is to be continued later. In a second, Mr. J. C. M'Lean accounts for the appearance of the swamp-hen, or bald coot, in localities in New Zealand where it was previously unknown, by the clearance and drainage of many of its former haunts.

IN the Report for 1901 on the Lancashire Sea-Fisheries Laboratory at Liverpool and the Sea-Fish Hatchery at Piel, Prof. W. A. Herdman directs attention to the urgent need on the Lancashire coast of a special steam vessel for the purpose of scientific and statistical work. The Fisheries Branch of the Irish Agricultural Department has now such a steamer working under the direction of a scientific adviser; and if similar investigations could be undertaken on the opposite side of the channel, and the two vessels worked on a common programme, Prof. Herdman is of opinion that "this most definitely circumscribed area of the British seas would be adequately investigated." It is earnestly to be hoped that the necessary funds may be obtained without difficulty. The general work of the laboratory has been carried on with success. At the Piel hatchery attention was confined during the year to the flounder, but in the current year more attention is to be devoted to the incubation of the eggs of the plaice. Appended to the Report is an account of the morphology and life-history of the plaice, by Messrs. Cole and Johnstone, forming No. 8 of the *L.M.B.C. Memoirs*. This appears to be the most elaborate account of any single species that has hitherto been published, and reflects the greatest credit upon its authors, who have devoted two years to their task. The plaice, which is one of the most important of the British food-fishes, is a local and sedentary type on which the effects of excessive fishing would be almost sure to make them, selves felt, and it has been the subject of more than one Government investigation. The importance of a full knowledge of the structure and habits of this fish, such as the authors give us, can- therefore, be scarcely overestimated. Much is to be hoped from the experiments in hatching and rearing the eggs and fry of the species alluded to above, for, as Prof. Herdman well observes, hatching and rearing are the real objects of institutions like the one under his direction, "And scientific men who have charge of fish-hatcheries will not be content till they have succeeded in rearing into young fish, at a reasonable cost, a sufficiently large proportion of the fry which they can now hatch from the eggs by the million."

WE have recently noticed Mr. D. G. Elliot's "List of the Land- and Sea-Mammals of North America," published at Chicago (NATURE, January 9). Since then we have received a copy of another work on nearly the same subject, prepared by Messrs. Miller and Rehn and issued by the Boston Society of Natural History. It is entitled "Systematic Results of the Study of North American Land-Mammals to the Close of the Year 1900," and embraces a larger area than Mr. Elliot's list, as it includes in North America the whole of the continent down to the isthmus of Panama and the West India Islands. It also serves to show, even more plainly than Mr. Elliot's list, the enormous additions lately made by the active zoologists of the United States to our knowledge of the North American mammal-fauna. Whereas Mr. True in 1885 only included about 400 species in his summary of this mammal-fauna, the authors of the present work enumerate no less than 1450 species and subspecies. Whatever may be the opinion of other naturalists about the status of some of these species and subspecies, all will allow that Messrs. Miller and Rehn have furnished us with a very useful summary of the results of the study of the North American mammals during the past fifteen years.

A WORK on "Meteorologische Optik," by Prof. J. M. Pernter, is in course of publication by Herr W. Braumüller, of Vienna and Leipzig, and the first part has been received. Prof. Pernter has given so much attention to the physical side of meteorology, and the analysis of optical phenomena, that his complete work ought to be of great interest. The part of the subject already treated is too general to admit of review, and we propose to defer our notice of the work until the whole of the parts have been published.

A SECOND edition of Prof. J. M. Coulter's inspiring little text-book entitled "Plant Relations: a First Book of Botany," has been published by Messrs. Hirschfeld Brothers. The chapters dealing with plant societies have been revised both in text and illustration, but otherwise few alterations have been made. As remarked in the review of the first edition (March 8, 1900, vol. lxi. p. 442), the book is an interesting and refreshing little manual, which ought to receive the attention of the teacher as well as the pupil. It should be of real service as a guide to nature-study.

WITH the laudable object of bringing science and scientific principles into every-day life and thought, a society has been formed and has issued a journal under the title of *Life*. The organisation at present has no name and its only designation is "our Society." A useful department of the journal is that in which advice is given as to the choice of books on various branches of science. There is an article on medical training and ideals, one on science and art in literature, and a third on the inaccuracies of the Old Testament—a subject which is perhaps better left alone by a society which hopes for success. The journal is edited by the secretary, Mr. R. A. Buddicom, 17 Craven Hill Gardens, Hyde Park, London, W., to whom all communications should be addressed.

THE *Transactions* of the Epidemiological Society (new series, vol. xx. 1900–1901) show that the Society is doing much to encourage the scientific study of disease. Dr. P. Manson, in a paper on some problems of tropical epidemiology, describes the work which has been done to establish the connection between mosquitoes and malaria, and suggests directions of further development. Why is it that Samoa, to take an instance, is free from malaria, while Mauritius has the disease present? The answer is probably that there is some organism in Samoa which is fatal to the malaria-bearing mosquito—Anopheles—while in Mauritius the insect can flourish; but the reasons for such differences are not clearly understood, and a systematic inquiry must be made before the conditions inimical to Anopheles can be exactly known. Similar remarks apply to diseases other than malaria; and Dr. Manson points out that expeditions to discover the causes and remedies of such diseases are even more necessary than expeditions to determine points of geological or geographical interest. Another paper in the volume is on plague in the nineteenth century, by Dr. A. K. Chalmers, who gives particulars of the outbreak of plague in Glasgow. Rats were plentiful in the affected houses, but they appeared to have escaped infection. Nearly three hundred rats were examined, but nothing suggesting plague was found. These results were in marked contrast with those described by Dr. Tidswell, of Sydney, at the close of Dr. Chalmers' paper. The facts obtained at Sydney showed conclusively that the plague was transmitted by fleas from infected rats. Among other papers we notice one on the diagnosis of plague, by Dr. E. Klein, F.R.S., which has already appeared in NATURE (vol. lxiv. p. 91); soil and typhoid fever, by Dr. J. T. R. Davison; and principles determining the geographical distribution of disease, by Dr. L. W. Sambon. A portrait of the late Prof. Max von Pettenkofer, of Munich, forms the frontispiece of the volume, and an obituary notice of this eminent investigator appears among the contents.

THE question of the nature of red phosphorus is one that has been frequently discussed, the general trend of the evidence being to show that red phosphorus is a polymer of white phosphorus. Some new and interesting experiments on this subject are contributed by Dr. R. Schenck to the current number of the *Berichte*. Starting with the well-known equation of van 't Hoff $-dC/dt = k.C^n$, in which C is the concentration, t the time, and n the number of molecules taking part in a reaction, he determines the velocity of transformation of white into red phosphorus in solution in phosphorus tribromide at 172° C. and 184° C., and finds that $n = 2$ is the only value of n which gives a constant value for k in the velocity equation. From this the conclusion is drawn that the equation $(P_4)_2 = P_8$ represents the first stage of the conversion of white into red phosphorus. It is, however, quite possible that this only represents the first stage in the process, the differences in the properties of the two varieties being so great that it is unlikely that they could be caused by such a small change in molecular weight.

AN important discovery in medical science is announced by M. Armand Gautier in the current number of the *Comptes rendus*. He has found that sodium methylarsenate, injected into the blood in minute amounts, is an absolute cure for malarial fever. Particulars are given of the treatment of nine cases, all of which had been contracted in Africa, and which were of such a severe type as to be refractory to large doses of quinine. The nine cases were rapidly cured, two only showing a slight relapse, and these yielded at once to a second injection. The progress of the cure was followed in each case by the examination of the blood, and the treatment was always followed by the disappearance of the specific hematozoa. The salt was also found to suppress entirely the anæmia associated with malaria. M. Gautier regards the results as sufficiently definite to authorise the substitution of this drug for quinine in pernicious malaria, although it still remains for further researches to determine the best dose, and whether administration by the mouth or hypodermically is to be preferred.

A COMPLETE index of the first thirty volumes of the *Journal de Physique* (1872–1901), arranged both according to authors and according to subject-matter of papers, has been announced.

THE behaviour of liquid sulphur dioxide as a solvent has been very completely investigated by Messrs. Walden and Centnerszwer, an account of whose researches is contained in vol. xxxix. of the *Zeitschrift für physikalische Chemie* (pp. 513–596). It is found that liquid sulphur dioxide easily dissolves a large number of (binary) inorganic salts and most salts of organic bases. The solutions of these salts are good conductors of electricity. The simple laws which regulate the conductivity of aqueous solutions of salts are in general not valid for the sulphur dioxide solutions. Amongst these may be mentioned Kohlrausch's law of the independent wandering of the ions, Ostwald's dilution law, the law according to which the molecular conductivity approaches to a maximum with increasing dilution, and the rule according to which the increase in the conductivity with the dilution is the same for all binary salts. The conductivity of solutions has been investigated at temperatures ranging from the freezing point of liquid sulphur dioxide to its critical point. The molecular conductivity increases at first with the temperature, reaches a maximum at a temperature dependent upon the nature of the dissolved salt, and then decreases with a further rise of temperature, becoming finally zero at the critical temperature, although the salts remain dissolved even at temperatures above the critical temperature. The authors conclude from this observation that electrolytic dissociation in solutions is an essential property of, or conditioned by, the liquid state of aggregation. Determinations of the molecular weight of dissolved salts by the boiling-point method give values higher than the normal, from which it would appear that the molecules of the dissolved salts are to a considerable extent polymerised, or form complex associated molecules containing molecules of the solvent.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Dr. Worley; a Pochard (*Fuligula ferina*), European, presented by Dr. H. S. Jameson; a Smooth-headed Capuchin (*Cebus monachus*) from South America, a White-fronted Capuchin (*Cebus albifrons*), a Hoary Fox (*Canis vetulus*) from Brazil, a Blue-fronted Amazon (*Chrysotis aestiva*), five Giant Toads (*Bufo marinus*) from South America, an American Green Frog (*Rana halecina*) from Central America, two Gangetic Trionyx (*Trionyx gangeticus*) from India, deposited.

OUR ASTRONOMICAL COLUMN.

THE NEW BRUCE SPECTROGRAPH FOR THE YERKES REFRACTOR.—This instrument has been provided from funds supplied in 1899 by Miss Catherine Bruce and the Rumford fund of the American Academy of Arts and Sciences. The arrangement of the various parts has been designed in view of obtaining the greatest possible rigidity and uniformity of temperature, as the principal work for which it is to be employed is the determination of velocities in the line of sight. To this end several departures have been made from ordinary designs. The foundation consists of two castings rigidly connected by a framework of steel tubes, one of these castings, weighing about 200 pounds, being attached to the massive terminal ring of the 40-inch refractor by eight bolts. The collimator tube is firmly attached to this and the second casting, which latter also holds the framework on which the prism train is mounted. It was decided to use three prisms of such angle that the total deviation was 180°, thereby rendering the instrument more compact and free from flexure. The optical train, consisting of the correcting lens, collimating lens, prisms and camera lens, were made by Brashear from formulæ supplied by Prof. Hastings. The correcting lens is 57 mm. aperture, and is so designed that when placed 100 cm. in front of the focus of the 40-inch for λ 4500, the angular aperture of the large lens is not altered. The performance of this lens has been found to be very satisfactory, rendering it possible to obtain a star spectrum of uniform width from λ 4300–λ 4700.

The collimator has a triple cemented lens of 51 mm. aperture and 958 mm. focus.

The first set of prisms, made from Mantois glass, was not satisfactory, and has been replaced by prisms made from glass supplied by Messrs. Schott and Co., of Jena. These are not perfect, but have given sufficiently good results to warrant their adoption. The refracting angles are about 63½°.

Two camera lenses are provided, one being a Zeiss anastigmat, aperture 71 mm., focal length 449 mm., the other a triple cemented lens designed by Prof. Hastings, with aperture of 76 mm. and focus 607 mm.

For the region of H_γ the dispersion of this spectrograph is almost identical with that given by the Mills and Potsdam III. spectrographs.

For temperature control the whole instrument is enclosed in a double-walled case of aluminium; thick felt is packed in the space between the two metal sheets, and a helix of thin wire distributed through this provides a convenient means of keeping the temperature of the prism chamber almost constant for a considerable time. For comparison spectra, electrodes of titanium and iron are used, and also a vacuum tube of helium.

In following, the method devised by Huggins of using the slit plate as a reflector has been adopted, several variations being made to avoid the inconvenience of having the two slit-jaws in different planes with respect to the collimator axis.

An extensive series of preliminary photographs has been taken and reduced, and the instrument is now in use for standard determinations of spectroscopic binaries, &c., which can only be detected by the variable radial velocity deduced from the displacement of spectrum lines (*Astrophysical Journal*, vol. xv. pp. 1–27).

THE STRATIFICATIONS OF HYDROGEN.[1]

THE following pages give the outcome of attempts to prepare pure hydrogen, and experiments on the stratifications exhibited by the purified gas under the influence of an induction current. The researches were commenced in 1884 and have been continued intermittently to the present time.

Strips of palladium foil were charged with hydrogen by the electrolysis of dilute sulphuric acid, a 4-cell Grove's battery being used for one hour. After drying, the palladium strips were put in a glass tube and sealed between the hydrogen generator and vacuum tube. At first, crude gas from the generator was used to wash out the apparatus, and after many fillings and exhaustions—the last to the highest possible point—the generator and tap were sealed off, leaving only the palladium and drying tubes attached to the apparatus. A portion of the palladium was now gently heated; the gauge sank 12 cm., when it was again well exhausted and a little more hydrogen liberated. This was repeated three times, when the tube was exhausted to the stratification-point—about 4 mm.

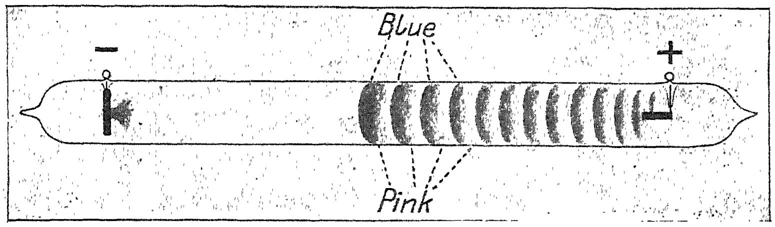

FIG. 1.

Parti-coloured Stratifications.

The strata were twelve in number and of a slightly concavo-convex button-shape, each of a blue colour on the convex side facing the negative pole, and pink on the other side. On eversing the current, the buttons faced round, always presenting

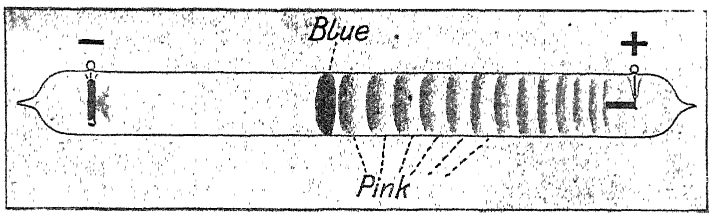

FIG. 2.

the blue face to the negative pole. Examination with a spectroscope showed strong hydrogen lines in the pink parts and both hydrogen and mercury in the blue parts. Fig. 1 shows the appearance at this stage.

The exhaustion was now raised to 2 mm., when the whole of the blue faces of the parti-coloured button suddenly migrated to one bright blue, well-formed button, nearest the negative pole, all the other buttons remaining pink. The appearance is shown in Fig. 2. Round the negative pole an indistinct halo showed both mercury and hydrogen; but on the blue button mercury only was detected, not a trace of even the brightest hydrogen line being there seen. On the pink portions the hydrogen lines were in excess, but mercury could be seen all along the tube.

A slight difference is produced in the purity of the colours of the strata according as aluminium or platinum poles are used. A pair of vacuum tubes was made, one having the usual shaped aluminium poles, the other having platinum poles of a special construction. Each terminal was of double wire, at one terminal bent into the form of a ring and at the other a straight pole. The ends of the wires forming the poles were sealed through the tube close together, but not touching, and terminated in loops outside, so that

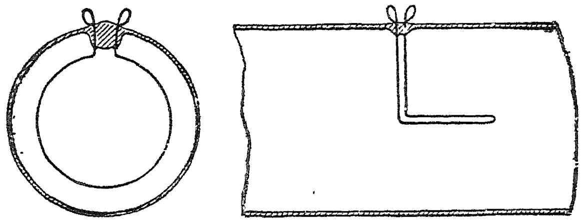

FIG. 3. (Full size.)

they could be raised to red or white heat by connecting them with a few battery cells. The arrangement will be readily understood by reference to the accompanying drawings (Fig. 3). Thus heat could easily be applied during exhaustion, first to one pole and then to the other, even while the induction spark was passing. At first much gas was liberated from the platinum, but by repeated heating, pumping, and passing the spark, all the occluded gas was abstracted, and then the fillings with hydrogen and subsequent operations were commenced.

The general plan of the apparatus is shown in the drawing (Fig. 4). At the end furthest from the pump is the hydrogen generator, A, consisting of a U-shaped tube filled with dilute sulphuric acid, having in one leg a plate of amalgamated zinc, B, and in the other a sheet of platinum, C. Both the platinum and the zinc are connected metallically to platinum wires sealed through the glass. A funnel with a stopper, D, sealed to the outer limb of the generator admits dilute acid when required. A tap, E, on the other limb enables the reservoir of hydrogen to be disconnected from the rest of the apparatus. Following this tap is a battery of three tubes, one, F, containing small lumps of dry caustic potash, the second, G, and the third, H, tubes containing phosphoric anhydride. Between the second phosphoric anhydride and the vacuum tube is another tube having sealed on to it, comb-like, seven projecting arms, J J, each containing a strip of palladium foil saturated with hydrogen.

The vacuum tube, K, is eight inches between the terminals and three-quarters of an inch diameter; it comes next to the comb, and then between it and the pump is a battery of tubes, each twelve inches long, to keep out the mercury. The first tube, L, is divided by a constriction in the middle, and contains, in the half next the vacuum tube, bright metallic copper, in the other half sulphur. The three next tubes, M, M, M, contain sulphur, but in the middle of each are placed a few grains of iodine separated from contact with the sulphur by a

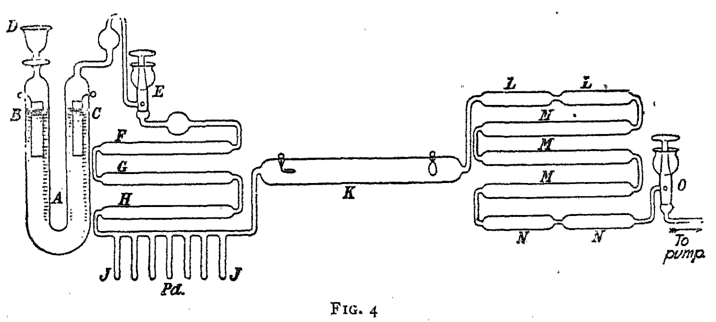

FIG. 4

plug of asbestos on each side. The sulphur is prepared by keeping it fused at a temperature a little below its boiling-point till bubbles cease to come off, so as to get rid of water and

[1] Paper read at the Royal Society on February 6 by Sir William Crookes, F.R.S.

hydrogen compounds. It is then allowed to cool, and is pounded and sifted so as to get it in the form of granules, averaging a mm. in diameter. Ignited asbestos is packed at each end of the tubes to keep the contents from blowing out when the vacuum is proceeding, or air is suddenly let in. Next follows a tube, N, N, constricted in the middle, containing in the first half phosphoric anhydride, and in the second finely powdered dry caustic potash. A tap, O, connects the apparatus with the pump to prevent diffusion of mercury when the pump is not in use. All parts of the apparatus were built up in place and sealed together with the blowpipe. The glass was new, and the apparatus had been kept apart from mercury until it was sealed together.

The apparatus was exhausted from air, the tap E being closed and D open. Electrolysis was then commenced (D being closed), and the tap E was slightly turned until the escape of hydrogen into the apparatus was equal to the speed of its generation. The apparatus was filled, and several times exhausted, until no improvement in the spectrum or stratifications could be seen. The electrolytic cell was then sealed off at a narrow constriction between the first potash tube, F, and the phosphoric anhydride tube, G. After good exhaustion, one of the branch tubes of palladium was heated, when the gauge sank several centimetres. Exhaustion and refilling from fresh palladium were repeated until no alteration was detected in the appearance of the strata. Then, for the first time, I obtained hydrogen strata showing no blue, either throughout the tube or concentrated in front, whilst the most careful examination showed no mercury. The stratifications were all pink, and showed the hydrogen lines strongly.

Many disadvantages were noticed in the apparatus just described, the chief being the danger of introducing more impurities than were kept out by the copper, sulphur and iodine tubes. The palladium method of introducing hydrogen was not altogether satisfactory, as only small quantities could be dealt with, and occasionally at a critical point the store was exhausted. Also, the electrolytic generator of hydrogen was too small. It was decided, therefore, to devise and fit up an entirely new piece of apparatus. In this another method was used for keeping out the mercury. It had been noticed that the diffusion of mercury from the pump proceeded the more slowly as the distance from the pump and the narrowness of the connecting tubes increased. It was thought that by introducing a long narrow spiral between the pump and the apparatus, one complicated system of tubes, with their attendant dangers, could be removed; the result showed this supposition to be correct. Two vacuum tubes were employed, one having aluminium, the other platinum terminals. The hydrogen generators were increased in size and number, and were so distributed that they could be sealed off one after the other during the progress of the experiment.

Stratifications in Pure Hydrogen.

The arrangement of the apparatus is shown in Fig. 5. The three hydrogen generators are called Nos. 1, 2 and 3. In No. 1 the gas is generated by the action of hydrochloric acid on zinc. This crude hydrogen is only used to drive out the air from the rest of the apparatus and to remove the air dissolved in the liquids. When it had done its work, the generator was sealed off between Nos. 1 and 2, at A. It was considered that having the apparatus to begin with full of even somewhat impure hydrogen was better than starting with it full of air. The second and third generators contain at the bottom a pasty amalgam of mercury and zinc forming one pole, and a piece of platinum forming the other pole; the electrolyte is dilute hydrochloric acid. Platinum wires sealed through the sides of No. 3 carry the current from three Grove's cells to the interior. After the apparatus has had generator No. 1 removed, a large quantity of hydrogen is passed through from the second generator, with the object of replacing the impure hydrogen by some of a purer quality. When No. 2 is exhausted, it also is sealed off at B, leaving only the third generator with its drying tubes connected with the apparatus. Before sealing off No. 2, filling and exhausting is carried on until the hydrogen shows no impurity when spectroscopically examined in a capillary tube attached to the vacuum tube. The gas from the first and second generators bubbles first through strong caustic soda, C, C, C, to remove any acid carried over from the generators, then through strong sulphuric acid, D, to take away the bulk of the moisture and thus save the drying tubes; it then passes through the purifying arrangements more especially connected with the third generator. Having sealed off Nos. 1 and 2, gas is evolved from No. 3 generator. Hence it passes through strong sulphuric acid in the tube H; then over a tube filled with granulated caustic soda F; and next through a tube, G, tightly packed with phosphoric anhydride. H and I are two taps, having a reservoir, K, between them. When full of gas, H and I are closed, and the tubes L and M, after having been exhausted to a high point, can then be fed with limited amounts of pure dry hydrogen by slightly opening tap I and closing it when equilibrium is restored between L, M and K. N is a spiral of narrow glass tubing immersed in a beaker of ice and water. At O is a tap to keep mercury from diffusing into the pump if the apparatus has to be left all night. The vacuum tube, L, is provided with aluminium poles and the tube M has the platinum poles made double for heating purposes, as shown in Fig. 3.

Hydrogen from the first generator was passed through the apparatus for two hours, when it was sealed off. The whole apparatus was exhausted to a high point and No. 2 generator was set to work. Hydrogen was passed several times at full pressure through the apparatus for one or two hours and then exhausted to the stratification point. During these operations the platinum terminals of one of the vacuum tubes were heated to full redness and the current was kept on both tubes for some hours to drive off occluded gases.

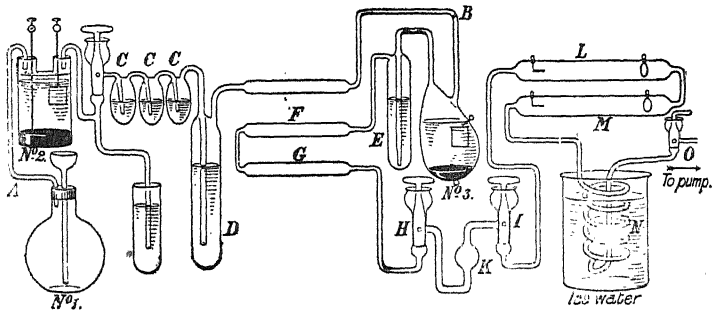

FIG. 5.

Finally, the second generator was sealed off and hydrogen used from the remaining generator. After much washing out with hydrogen at the ordinary pressure, exhaustion and re-filling were continued, and finally the reservoir K was filled, both taps, H and I, being closed. The tubes were highly exhausted to the non-conducting point, and tap I opened and then closed, so as to introduce a little hydrogen. H was then opened and again closed, so as to equalise the pressure in I, and exhaustion proceeded to the stratification point. At first the strata were irregularly coloured with a suspicion of blue on one face, but as the operations just described were continued, the blue faces disappeared, the stratifications assumed a pure pink hue and showed the hydrogen spectrum alone; no mercury was detected in any part of either tube.

From the first to the eighth filling the strata were pink with a trace of slaty blue colour on the faces next the negative pole. From the tenth filling the blue faces disappeared, and after the twentieth filling no trace of blue could be seen and the spectrum of hydrogen alone was visible.

On examining the spectra of the stratified gas in the two tubes, each showed strongly the line spectrum of hydrogen; but while the spectrum in the platinum-poled tube showed pure red, blue and green lines on a black ground, that in the aluminium-poled tube showed in addition the fainter hydrogen line spectrum in the yellow and orange. This result may be due to the greater surface exposed by the aluminium poles; it was not further examined.

Having at last succeeded in getting hydrogen free from mercury, experiments were instituted to verify the inference that

the blue components of the blue and pink strata usually attributed to hydrogen were really due to the presence of a trace of mercury.

Origin of the Blue Component of Parti-coloured Stratifications.

I used an apparatus similar to the last, but with only one generator. If my idea was correct, that the mercury in the course of a few hours diffused into the hydrogen tube from the pump when it was not at work, there ought to be an access of blue faces to the pink buttons after the exhausted apparatus had been at rest. After filling with hydrogen and exhausting several times, a hydrogen vacuum was obtained showing no blue faces to the pink strata. The apparatus was then left all night and the stratifications examined next morning. The blue colour to each face was now unmistakably visible. The refilling with hydrogen and exhausting was then continued. It was not possible in this way to get the tube entirely free from mercury, although it got less and less, as shown by the diminution of the blue faces.

Occasionally, when no mercury was present, a faint blue edging to some of the front pink strata was seen. This blue was too faint to show lines in its spectrum. After much searching, the blue tint was traced to the phosphoric drying tubes. A clean tube was taken for stratifications and sealed to the apparatus used in the last experiments. The whole was exhausted to a high point, and one of the phosphoric anhydride tubes was gently heated with a gas flame, the current kept going. Instantly a flood of blue light swept through the tube, and when concentrated in a narrow constriction the light showed a complicated spectrum which was not recognised: none of the characteristic lines of the phosphorus spectrum could be seen in it. The tube was cleared of the blue colour by introducing hydrogen and pumping it out a few times, and then hydrogen was introduced and exhaustion continued to the stratification point. The strata now were pink, with no appearance of blue. Warming the phosphoric anhydride tube at once reproduced the faint blue edging to the pink discs. This blue colour was different both in tint and intensity to the blue colour produced by mercury, but it was too faint to show a spectrum except in the constricted part.

It is of importance to ascertain whether the body producing this blue colour can be removed from the phosphoric anhydride. The drying tube was again heated to the subliming point of the anhydride, hydrogen passed in, and the pump worked until the vacuum was almost non-conducting. The heating, passing in hydrogen and pumping were several times repeated, the impurities diminishing each time. Ultimately a point was reached when, the tube being non-conducting, heating the phosphoric anhydride did not communicate any gas to the vacuum tube. At this stage the phosphoric anhydride still retained unimpaired its affinity for water. In any accurate experiment, therefore, the phosphoric anhydride tubes should have a preliminary heating in a vacuum to eliminate the impurity. This may be done with several tubes at a time, when they can be sealed at each end and preserved for future use.

It is thus seen that this blue glow is due to some impurity in the phosphoric anhydride. Likewise I have shown from the examination of its spectrum that it is not due to phosphorus. The glow probably is due to some intermediate oxide of phosphorus. In any accurate work with the mercury pump, where phosphoric anhydride is used as the drying agent, this source of impurity must not be overlooked.

An addition to the apparatus was made, a supplementary tube sealed on containing a grain of corrosive sublimate. This was used as being non-volatile at the ordinary temperature, but easily vaporised by heat. The experiment last described was continued, and immediately after the phosphoric blue edge appeared fresh hydrogen was let in and exhaustion continued till the faint blue was eliminated. The mercury salt was then heated, when immediately a rich blue edging appeared on the face of each pink stratification and the yellow lines of mercury shone out distinctly. Mercury blue is of a fuller colour than that of the phosphoric blue.

Conclusions; Chiefly Theoretical.

The phenomenon of blue faces on the pink discs is probably due to some such action as the following:—At the exhaustion necessary to give stratifications, there is a wide dark space round the negative pole. Here the negative electrons (radiant matter), issuing from the pole with enormous velocity, have sufficient energy to clear a space in front of them to a distance varying with the degree of exhaustion.

Dr. A. Schuster considers that the discharge through mercury vapour in a vacuum tube, when quite free from air, will not give rise to stratifications, or to the dark negative space.[1] My own experiments (*Journ.* of the Inst. Electrical Engineers, vol. xx. p. 44) show that the dark space will form in pure mercury vapour. Whichever view may be correct, there is no doubt that if stratifications in mercury vapour are not altogether unknown, they are much more difficult to produce than similar phenomena in hydrogen or other diatomic gases. At a certain critical stage of the exhaustion, when both hydrogen and mercury are present, I obtain both mercury and hydrogen strata.

It is known that in a vacuum tube, at an exhaustion approaching the stratification-point, any slight obstruction, such as constriction in the tube, or a series of wires sealed in, will cause luminous strata to hang round the obstruction. In a similar way, the hydrogen strata afford an anchorage, as it were, for the mercury, each hydrogen luminosity having a little blue glow of mercury hanging on to it; whereas, were there no hydrogen, no mercury stratifications would be seen.

The pink and blue luminosities show where the electrons and gaseous atoms meet; when the speed of the electrons is suddenly diminished, the shock throws the atom into greater vibration, which, being communicated to the ether, produces vibrations of definite wave-lengths, constituting the special spectrum of the atom. The dense mercury atom is not driven back so much as the lighter hydrogen atom—hence the blue front to the pink buttons. A very little difference in the exhaustion suffices to break the adhesion between the mercury and the hydrogen; then the mercury vapour diffusing along the tube meets the electrons from the negative pole and is swept back to the head of the hydrogen strata, and becomes apparent as a single button of blue light.

Radiant Matter. Electrons.

I have spoken of "radiant matter" and "electrons" as if they were identical. Nearly twenty-five years ago I was led by experiments in highly rarefied tubes to assume the existence of matter in an *ultra-gaseous* state. Later, in a lecture delivered before the British Association at the Sheffield Meeting, 1879 (*Chemical News*, vol. xl. pp. 91, 104, 127), I first used the expression "radiant matter," or matter in the ultra-gaseous state, to explain the novel phenomena of phosphorescence, trajectory, shadows, mechanical action, magnetisation and intense heat. "In studying this fourth state of matter," I said, "we seem at length to have within our grasp and obedient to our control, the little indivisible particles which with good warrant are supposed to constitute the physical basis of the universe. We have seen that in some of its properties radiant matter is as material as this table, whilst in other properties it almost assumes the character of radiant energy. We have actually touched the borderland where matter and force seem to merge into one another" (*Chemical News*, vol. xl. p. 130).

In twenty-five years one's theories may change, although the facts on which they are based remain immovable. What I then called "radiant matter" now passes as "electrons," a term coined by Dr. Johnstone Stoney, to represent the separate units of electricity, which is as atomic as matter. What was puzzling and unexplained on the "radiant matter" theory is now precise and luminous on the "electron" theory. Thus my early hypotheses fall into order by the substitution of one expression for the other. A chemical ion consists of a material nucleus or atom of matter constituting by far the larger portion of the mass, and a few electrons or atoms of electricity. The electrons are the same as the "satellites" of Lord Kelvin and the "corpuscles" or "particles" of J. J. Thomson.

Electrons probably leave the negative pole with a velocity nearly uniform, modified to a considerable extent by the degree of exhaustion, and to a less extent by the electromotive force behind them. Many experiments—the details I must leave to a future occasion—show that the liberated electrons do not behave as a gas, *i.e.* they have not properties dependent on inter-collisions, mean free path, &c.; they act more like a fog or mist, are mobile and carried about by a current of air to which they give temporary conducting powers, clinging to positively electrified bodies and thereby losing mobility, and settling on the walls of the containing vessel if left quiet.

[1] Dr. A. Schuster, "Experiments on the Discharge of Electricity through Gases," *Roy. Soc. Proc.*, vol. xxxvii. p. 318.

On the other hand, the crowd of hydrogen or mercury atoms, by virtue of molecular motion and inter-collisions, act as gases. Whilst their *mean* free paths are conditioned by the degree of exhaustion, there may be amongst them a certain number of *actual* free paths differing widely on each side of the mean. Under the influence of the electromotive force, and at the right degree of exhaustion, these atoms arrange themselves in groups,[1] while the rushing swarm of electrons driven from the negative pole meet them and render them visible. According to J. J. Thomson, the mass of an electron is about the 1/700th part of that of the hydrogen atom, and as these masses start from the negative pole in a vacuum tube with a velocity of the order of half that of light, it is easy to see that their heating, phosphorescent and mechanical power must be stupendous.

The basis of the electron, as I foreshadowed in 1879 in the case of radiant matter, is probably the same in all cases—the protyle from which the chemical atoms were assumed to be formed.

On the two-fluid theory, the electrons constitute free negative electricity, and the rest of the chemical atom is charged positively, although a free positive electron is not known. It seems to me simpler to use the original one-fluid theory of Franklin and to say that the electron is the atom or unit of electricity. Then a so-called negatively charged chemical atom is one having a surplus of electrons, the number depending on the valency, whilst a positively charged atom is one having a deficiency of electrons. Differences of electrical charge may thus be likened to debits and credits in one's banking account, the electrons acting as current coin of the realm.

SCIENTIFIC WORK OF THE GERMAN ANTARCTIC EXPEDITION.[2]

THE head of the German Antarctic Expedition, Prof. Dr. Drygalski, has sent from Cape Town to the home authorities a number of full reports on the work which had been carried on by the expedition up to the date of their despatch. As is well known, the ship, which had been specially built for the expedition, was long overdue at Cape Town, and her protracted non-appearance gave rise to some anxiety. We give the following extracts from the official report, which will shortly appear, in order to furnish evidence of the activity of the staff, and of the reasons for the great protraction of the voyage.

In the scheme of operations for the expedition, it had been arranged that visits to two land stations should be made during the voyage to Cape Town, in order to determine, by fresh comparisons with the absolute magnetic elements at those land stations, the changes in the magnetic character of the ship since its determination at Kiel before sailing. The magnetism of a new ship is always subject to changes in course of time, but these changes are more especially caused by change of magnetic latitude as the ship passes from one hemisphere to the other. With this object, the following places were selected as apparently desirable :—The Cape Verdes or Madeira, north of the magnetic equator, and Bahia or Ascension to the south of it.

After consultation with the magnetician of the ship, Dr. F. Bidlingmaier, I had selected Porto Grande in St. Vincent and Ascension. If, for any reason, Ascension proved to be inaccessible, it seemed advisable to adopt the usual plan, on board ship, and determine the deviation by swinging the ship on eight different courses in the open sea. During our stay at Porto Grande, which lasted until September 11–16, the magnetic observations were our principal business, and we succeeded in determining, on board the ship, the deviations in the Magnetic Declination, Total Force, and in Horizontal and Vertical Force due to her magnetism.

I myself landed, with two assistants, and set up a tent near the spot where the shore magnetic observations were being carried on, in order to secure time observations to rate our chronometers and watches, and also to make some observations of the force of gravity. Owing to the weather, we could make no astronomical observations.

My orders for the next part of the voyage were to cross the equator on the 18th meridian, and then to make for Ascension. The object of the first position was to verify the sounding of 7370 metres (4030 fathoms) [the greatest depth on the line], which had been obtained by the French man-of-war *La Romanche* in 0° 11′ S. and 18° 15′ W. As this figure is not mentioned on the British charts of soundings, nor in the recent critical representation of sea depths, by Prof. Dr. Supan, I therefore wished to trace its possible connection with the great depths of the Brazilian basin.

The visit to Ascension was to attain the objects above named. It was evident enough that the carrying out of this plan would present some difficulties, for the usual sailing track to the Cape (which was best for our ship, owing to the low power of her engines, which would not allow of steaming against the S.E. trade with its accompanying sea) crosses the equator far to the westward, probably as far as the 25th meridian. A visit to Ascension would entail our steering a south-easterly course immediately on leaving the Cape Verde, so as to be able to make a south-westerly course to the island under sail. The course indicated was to be first tried and tested as to whether it would take too much time. We crossed the belt of calms under steam, between the two trade winds. In this swell the *Gauss* rolled, at times very heavily, so that much glass or other breakable articles in the laboratory came to grief, while the ship, under sail, even with a stiff breeze and a good deal of sea, had been remarkably steady. This swell retarded our progress considerably, as of course our speed was greatly reduced. This was aggravated by increased fouling of the bottom. As the ship was very low in the water, the screw well, through which the screw and rudder could be lifted, on meeting ice, so as to preserve them from damage, may have contributed to the prolongation of the voyage. In short, we proceeded very slowly along the prescribed track, where the wind failed us, and the currents at least gave no help, though the engines worked perfectly, and gave promise of a very satisfactory performance whenever we should come into a state of sea checked by the presence of ice.

All these impediments retarded us with enhanced insensity when we met the S.E. trade on the line. This was very fresh (and we should have liked to have had a similar force in the N.E. trade), but we could make no use of it, as it was dead ahead on our course for Ascension, and it brought with it a trying swell and current. The rate of the ship got less and less, and at last stopped entirely on October 5. In these circumstances, as time was getting on (we crossed the line a few days after the entry of the sun into south declination on October 1, so that we ran directly from the northern into the southern summer), it seemed therefore desirable to reconsider our plan and give up the Ascension visit entirely, and so on October 6 I decided to do this and use the existing S.E. trade for a run to the Cape, starting on that day. As soon as we changed our course we made at once a speed of six or seven knots. On October 7 we disconnected the engines and made sail, but the wind did not last. On October 9 the S.E. wind died away, and these light winds continued, with some slight exceptions, up to Cape Town. The *Gauss* always made very short daily runs, so that we had a very long passage. The light winds and fair weather were the cause, as we had only one storm, November 18–20, just at the end of the voyage. We were naturally obliged to husband our coal so as not to lighten the ship too much.

On October 30, the after steam capstan was connected with Prof. Vanschöffen's vertical net, which was at a depth of

[1] In an address delivered before the Institution of Electrical Engineers, January 15, 1891, I gave an outline of a theory of stratifications in rarefied gases. The following quotation renders my meaning clear:—"If, in any much-frequented street, at some time when the stream of traffic runs almost equally in both directions, we take our stand at a window from which we can overlook the passing crowd, we shall notice that the throng on the footway is not uniformly distributed, but is made up of knots—we might almost say blocks—interrupted by spaces which are comparatively open ; we may easily conceive in what manner these knots or groups are formed: some few persons walking rather more slowly than the average rate slightly retard the movements of others, whether travelling in the same or in an opposite direction. Thus a temporary obstruction is created. The passengers behind catch up to the block and increase it, and those in front, passing on unchecked at their former rate, leave a comparatively vacant space. If a crowd is moving all in the same direction, the formation of these groups becomes more distinct. Hence mere differences in speed suffice to resolve a multitude of passengers into alternating gaps and knots. Instead of observing moving men and women, suppose we experiment on little particles of some substance, such as sand. If we mix the particles with water in a horizontal tube and set them in rhythmical agitation, we shall see very similar results, the powder sorting itself with regularity into alternate heaps and blank spaces. If we pass to yet more minute substances, we observe the behaviour of the molecules of a rarefied gas when submitted to an induction current. The molecules here are free, of course, from any caprice, and simply follow the law I seek to illustrate, and though originally in a state of rampant disorder, yet under the influence of the electric rhythm, they arrange themselves into well-defined groups or stratifications."—*Journ.*. of the Inst. Electrical Engineers, vol. xx, p. 10.

[2] Based upon an Article in *Der Tag*, Berlin, January 25.

2000 metres, and above it hung my deep-sea thermometers and five or six buckets, at the depth of 1500 metres. As each bucket came up, Dr. Gazert and Dr. Philippi speedily emptied it of its contents to search for bacteria and determine the amount of contained gas. Dr. Bidlingmaier, on the captain's bridge, regulated his registering apparatus in the meteorological screen, while Captain Ruser, beside him, kept the ship heading the swell and watched that the deep sea lines should not get foul and that the ship should not overrun them. The chief engineer, Stehr, on the after bridge watched the sounding apparatus with me. The first officer looked after the line as it came up and quickly dismounted the attached instruments. Vahsel saw to the running of the windlass itself, and Ott, in the small dinghy, picked up a huge albatross which Dr. Gazert had shot, and which was at once dissected by the practised hands of Dr. Werth. Then came up Dr. Stehr's question as to how many wheels were running on board at once, without actually counting them.

On Saturday, November 23, we reached Cape Town, having made some magnetic observations near the coast. On Saturday, December 7, the expedition will start again.

I can only say, in conclusion, that we shall never forget the warmth of the reception we met with, not only from the Imperial Consul-General von Lindequist, the members of his staff and the German colony, but also from the officials and scientific men of Cape Town, which rendered our stay there particularly pleasant.

THE USE OF ANATOMICAL CHARACTERS IN THE IDENTIFICATION OF WOOD.[1]

THE chief contributions to the study of the secondary wood of plants have been made by students of forestry, amongst which the names of Nördlinger, Hartig, Brandis, Gamble, and of many men connected with the Indian Forestry Department, deserve our respect. The school of Radlkofer (especially Solereder) has done good work in connection with the structure of the primary wood, which throws many sidelights upon that of the secondary wood, yet there is much less help to be derived from their studies than one would suppose, because there is frequently much difference in the structure of the two classes of tissue.

The grouping of the vessels and the medullary rays and the arrangement of the wood-parenchyma are frequently so characteristic that various genera can be recognised by a glance at the transverse section, *i.e.* horizontally as the tree stands; and, further, it is by no means rare to find the same structure running through a whole genus or, less frequently, through a whole order. A hundred genera could be cited which exhibit a strong family likeness, and of the Proteaceæ and Sapotaceæ it may be said that the description of the structure of the wood of one species will practically serve for the whole order. On the contrary, there are orders which appear to consist chiefly of exceptions, as in the case of the Celastraceæ, where it is difficult to find two genera with any important feature in common. The structure of the woody portion of cryptogams has been employed for years in the study of fossil plants; that of the monocotyledonous trees and of the conifers is notoriously uniform, and is as sure a guide to their position in the natural system as any external character. Why then should not the same rule apply to the angiospermous dicotyledons, and for what reason should the thread be lost as soon as we pass from one division of the vegetable world to another? It seems a by no means extravagant idea that, inasmuch as it is quite indifferent to the welfare of a plant what the structure of its woody portion may be so long as it performs the mechanical duties imposed upon it, ancestral traits should be preserved undisturbed in the wood more than in any other part.

Ignoring this debatable question there is no doubt whatever of the economic importance of this study. There are not only so many kinds of timber in use in Europe and elsewhere, but there are great numbers which are destined to become useful, together making a variety with which no timber dealer can keep *en rapport* by the old method of rule of thumb. It is still more difficult in the colonies and in new countries to tell one wood from another, because the number of persons possessing the necessary training is smaller than at home. The popular and vernacular names are in many places so frequently duplicated or misapplied that they are useless as guides unless the structure of the wood be taken into account. Instances could be multiplied in which wrongly named timbers have been referred to their proper titles, and of inquiries for unknown woods being directed into the proper channel, and of cases in which attempted deception has been frustrated by the anatomical method.

For practical purposes it is rarely necessary to use high powers of magnification or to study the sculpture upon the walls of the cells. A pocket lens or a two-inch objective will frequently suffice to display the special character of the structure. If higher powers be used this individuality, as I may call it, is lost, as it is dependent upon the arrangement or complex of the elements. For instance, the radial or tree-like arrangement of the vessels in the wood of all the trees of the genus Quercus is recognisable by the naked eye, but it fails to be striking when viewed under a half-inch objective. This particular feature may be traced through the genera Corylus, Castanea, Ostrya, Castanopsis and Carpinus, but not in Fagus. The concentric undulating lines of vessels characteristic of the elms are also usually visible to the naked eye and can be traced in every

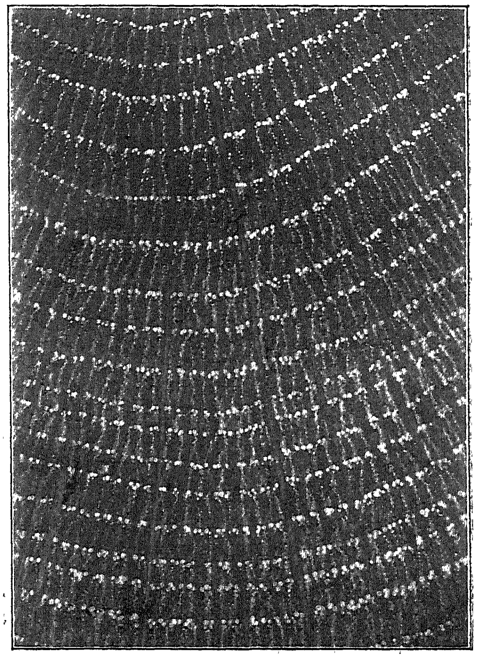

FIG. 1.—Oak. Transverse section × 3½.

species of Ulmus and, in a modified form, in Celtis, also in Ficus, Morus, Artocarpus, Maclura and Urtica.

It may at once be conceded that anything like a natural system of classification of woods by their structure is quite impossible at present. There are too many glaring exceptions and there is too little recorded information. Out of sixteen species of Caprifoliaceæ examined,[1] fifteen have the same type of structure, while the remaining one, *Viburnum Tinus*, L., is quite different; while out of nineteen species of Celastrus there were found no less than seven distinct types of structure.

Nevertheless, amongst such a number of different woods a guide to enable one to trace the name of any wood is a crying need, and several authors have attempted with more or less success to satisfy it. There are several by which the European woods may be identified, notably those by Mathieu, Hartig, Schwartz and Nördlinger, that of the latter embracing exotic woods also, to the number of 1100. Unfortunately, Nördlinger, whose work is otherwise unrivalled, relies upon the definiteness or indefiniteness of the boundary of the year's growth of wood in too great a degree, hence the student is led astray. Alfred Ursprung has recently shown how elusive this

[1] Based upon a paper read before the Society of Arts on December 4, 1901, by Mr. Herbert Stone.

[1] Sambucus, 2 species. Viburnum, 6 species. Lonicera, 8 species.

character is. From the examination of some 1500 species I am convinced that the character of the medullary rays (which, by the way, are anything but medullary in the secondary wood) is the most constant feature and should form the basis of an artificial key, but it separates the genus Betula, the rays of which are but a millimetre high on a vertical section from Alnus, where they may run to inches, and it cuts the Leguminosæ into two halves, one of which has bold spindle-shaped rays in transverse section (Ulex, Cytisus, &c.), while in the other the rays seem to meander amongst the vessels like so many limp threads (Mimosa, Gleditschia, &c.).

Nevertheless, a useful key may be constructed by first distinguishing those woods with two kinds of rays (many Cupuliferæ) from those having but one. The latter then fall into two groups, one having rays which have intervals between them of not less than the transverse diameter of the largest pores present, the other conversely having the intervals between the rays never greater than the pore-diameter, *i.e.* the rays diverge and run round or avoid the pores. These two types of rays are very clearly marked and have quite different aspects. The arrangement of the vessels or pores can then be usefully employed, as the concentric radial, tree-like or undulating groups, or uniform distribution of the pores is very constant in many genera, as are

FIG. 2.—Common elm. Transverse section ×3½.

also the equally varied forms assumed by the soft-tissue (wood-parenchyma), which comes next in order of importance. It would be out of place here to go into further detail, and it need only be pointed out that by following this sequence all members of the same genus except the aberrant forms fall together into the same ultimate group, which is not the case with Nördlinger's or any other key that I have used.

Many groups, or even whole genera, are so similar in structure that their species can only be distinguished by long acquaintance, *e.g.* Fraxinus, Acer, &c., and it is then necessary to have recourse to other features, such as the specific gravity, colour, smell, taste, hardness, behaviour with certain reagents, colour of their solution with water and alcohol, &c. Frequently these are so pronounced that a single feature may be sufficient to describe a species, as, for example, the offensively powerful cheese-like smell of *Goupia tomentosa* and the flinty hardness of *Lignum vitae*, hence it has often been urged that if a wood can be so readily identified by such simple means, why employ a more complicated and less accessible method. No one underrates obvious characters, but there are thousands of species, hundreds of which are employed in the arts, that have no pronounced feature of this kind to distinguish them. The value of the anatomical characters to the systematic botanist and to the trader is, however, in inverse proportion. The closer the resemblance in structure between the members of the same group the stronger the claim for a place in classification. On the other hand, the greater the dissimilarity the easier becomes their discrimination for commercial purposes.

CONFERENCE ON SCHOOL GARDENS.

A CONFERENCE on school gardens was held under the auspices of the Berkshire County Technical Education Committee at Reading College on Saturday. Mr. T. G. Rooper, one of His Majesty's inspectors of schools, read a paper on "School Gardens in England and in Germany," giving an account of those he has helped to institute in this country and others which he visited on the Continent. He dwelt, too, upon the provision made in Germany at the Pomological Institute for training elementary teachers, and one of his most interesting points was with regard to them. They are not, as here in England, expected in return for tuition, maintenance and travelling expenses, to attend courses of instruction during well-earned holidays, but they have the additional privilege of working at the Institute during term time, a substitute being paid to take their duty.

English school gardens, though at present comparatively few in number, are on all sides acknowledged to be the most practical yet instituted. Except in the case of those attached to continuation schools, no attempt must be made to utilise them for the technical teaching of gardening or otherwise than as mere training, mental and manual. A point obvious enough that was touched upon was that inspectors of schools should know something of horticulture if they are to report on school gardens and these are to be instituted in larger numbers. The importance of it is that, with very few exceptions, the inspectors are not at all well versed in the subject. County Councils cannot spend money directly upon elementary schools, but training of teachers they can arrange for, they can hold conferences such as the one here discussed, and their horticultural instructors may, and do, without breaking the law, give advice on the laying out of school gardens. Mr. J. C. Medd, in the course of his remarks, alluded to the Nature-Study Exhibition, with a view to holding which in London during next summer an association has just been formed. At this, which if it comes about will be greatly due to Mr. Medd's efforts, garden produce that may be in the proper condition at the time will no doubt be welcomed. Sir John Cockburn, lately Premier and Minister for Education in South Australia, is the chairman of the executive committee. Sir John, speaking at the Conference, alluded to "Arbor Day," upon which everyone in the antipodes who can plants a tree. The idea, one might say, is borrowed from America and is a very good one.

The difficulty of getting proper time for practical work was also touched upon by Sir John Cockburn, who said that, although one hour was all he could obtain at first, nevertheless, before he left South Australia, schools had been started in which only half the time was devoted to theoretical instruction.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—At the 232nd meeting of the Junior Scientific Club on Wednesday, February 12, two papers were read, viz. "Colour and Chemical Composition," by Mr. S. A. Ionides, Balliol College, and "The Centrosome," by Mr. A. D. Darbishire, Balliol College.

By his will, Sir J. H. Gilbert, F.R.S., who was Sibthorpean professor of rural economy from 1884–90, and who died on December 23, 1901, bequeathed the portrait of himself by his brother, Josiah Gilbert, to the University of Oxford, to be placed in the library of the Sibthorpean professor of rural economy.

DR. F. T. TROUTON, F.R.S., of Trinity College, Dublin, has been appointed Quain professor of physics in University College, London, in succession to Prof. H. L. Callendar, F.R.S.

DR. W. H. WILLCOX has been appointed deputy lecturer in hygiene at Bedford College for Women, on the resignation of

Dr. W. C. C. Pakes, who has been appointed bacteriologist to the Transvaal Government. The council has resolved that, in order to keep a permanent record of the legacy left to the college by Mrs. Morton Sumner, the lecturer in geology be hereafter called the Morton Sumner lecturer in geology.

THE papers read at the recent conference of science teachers, arranged by the London Technical Education Board, are appearing in the *Technical Education Gazette*, with reports of some of the speeches. The January number of the *Gazette* contains addresses on the teaching of hygiene, by Miss A. Ravenhill; mental school hygiene, by Dr. F. Warner; and the teaching of natural history, by Mr. F. E. Beddard, F.R.S.

THE Technical Education Board of the London County Council report that the reorganisation of London University is already having a marked influence for good on the polytechnics and other institutions. The advanced classes in science and engineering are being revised and brought up to a higher standard, gaps in the curriculum are being filled up, and more students are being induced to enter upon systematic courses of study, extending over three or four years, instead of attending isolated classes. Complete degree courses, under teachers of the University, will shortly be available for evening students at several of the polytechnics. The due recognition of engineering and higher commercial subjects was provided for by the establishment of separate faculties, and the Senate has now approved courses of study in which students will proceed to the degrees of B.Sc. and D.Sc. The regulations for the economic or commercial degree enable it to be gained in such subjects as the history, principles and organisation of banking, insurance, railway and shipping transportation, international commerce, local government, statistics, &c. By means of the Council's aid, the Senate has now determined on (1) the organisation of an institute of advanced chemistry, both organic and inorganic, at one centre; (2) the provision of advanced teaching in engineering at two centres; (3) the systematic organisation of the teaching of modern languages at all the University centres, including the polytechnics, and beginning with German; (4) the provision of a professorship of education in connection with the Council's proposed day training college for teachers; and (5) the appointment of University teachers in economic history and theory, commercial geography and history, banking, statistics, foreign trade, &c.

SCIENTIFIC SERIAL.

Bulletin de l'Académie de Sciences de St. Pétersbourg, 5th series, vol. xii.—On the compound (so-called stationary) radiants of shooting stars, by Th. Bredikhine (in French). The supposed existence of stationary radiant points (or radiant points of long duration) is an obstacle against all more or less admissible theories of shooting stars. Taking advantage of the 918 meteoric orbits calculated by J. Kleiber in 1891, and of subsequent data, the author concludes that each stationary (or long duration) radiant consists of several individual radiants, even when these radiants do not much differ from each other in their dates; this means that each stationary radiant is a compound radiant which originates from several individual radiants, each of which has its own position in space and its own origin, and all of which are intersected by the orbit of earth. Thus, in the well-known radiant of β Persei he finds "thirteen or fourteen different orbits, *i.e.* as many different streams" (p. 102). The author examines next the theories of Profs. H. H. Turner and A. S. Herschel, and concludes that "the deductions of Prof. Turner are only admissible under the impossible supposition that the earth moves with a uniform speed along a straight line. But if the theory itself is inconsistent, its secondary complications, such as the spinning of the meteoritic stream, the resisting medium, &c., have no more signification" (p. 115). Applying his explanation next to the polar stationary radiants of Mr. Denning, the author shows that in the radiant ζ Draconis (No. 36 of catalogue A), one may recognise "twelve different individual streams (twelve comets) apparently composing one single stationary radiant." The author's final conclusion is:—"A stationary radiant does not originate from a single individual stream or from one single comet; it must be named a compound radiant, because it is produced by several comets or independent streams. The phenomenon is so simple that all complicated and artificial theories are useless and superfluous. . . . Thanks to the numerous and careful observations of Mr. Denning, the phenomenon has lost its supposed individuality and has become decomposable and explicable."—On photographic observations of the satellite of Neptune at Pulkova, by S. Kostinsky (Russian; with a plate).—Report on zoological researches at Sebastopol in 1899, by A. Kovalevsky: hypodermal fertilisation with the leeches; on *Batracobdella latastii*; on *Helyle Tyrtowii* (n.sp.); on *Pseudovermis paradoxus*, Periasl.—On faint lines in stellar spectragrams, by A. Belopolsky.—On a MS. in Coptish language attributed to Dionysius Areopagita, by Oscar Lemm.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 23.—"Mathematical Contributions to the Theory of Evolution. XI.—On the Influence of Natural Selection on the Variability and Correlation of Organs." By Karl Pearson, F.R.S.

The influence of directed—natural or artificial—selection on the characters of a race is one which it is fundamental for the purposes of evolution to appreciate quantitatively. I have already shown in an earlier memoir of this series the effect of random selection, or what it is better to term random sampling, on the characters of a population. Isolation of a few individuals who form a random sample may produce very sensible modifications of race characters, but it is to directed selection that we must look for changes on the largest scale. The subject is a very broad and complex one—no less than the total effect upon a population containing individuals at all ages of a selective death-rate applied for a long period and a function not only of the organs of each individual, but of the relationship of these organs to each other, and of the stage of growth of the individual. In the present memoir, attention is confined to the influence of selection in altering a complex of organs, no reproduction taking place during the selection.

A very definite distinction is at once reached, namely, that between directly and indirectly selected organs. It may be said that, although it is possible for the recruiting sergeant to select stature, and in so doing differentiate the arm-length of his troop from that of the general population, yet that in natural selection we are given only the modified organs, and so we cannot tell which of them have been directly and which indirectly selected. Both are changed; how discover which was the source of the change? The answer is: In the same manner as we could distinguish between two recruiting sergeants, one of whom selected his troop from the general population by stature, and the other by cubit; in either case the stature and cubit would be both modified, but the mathematical theory of regression would enable us to distinguish between the methods of operating of the two men, and even between them and one who selected by *both* stature and cubit at once. The mathematical theory as developed in this paper shows us that, although the whole complex of characters may have been changed, still, if direct selection has only occurred in p out of n possible cases, there will be certain of the partial regression coefficients which remain unmodified and which will theoretically enable us to distinguish among the whole group of differentiated organs, between those directly selected and those modified only because they happen to be correlated with the directly selected organs. Thus the distinction becomes one of singular importance, for though the selection of a few organs modifies the means, variabilities and correlations possibly of the whole complex of characters, certain functions of those quantities remain constant, and such constants ought to be discoverable, at any rate in theory, and should serve as the criterion of a common origin, when we deal with local races as having been subjected only to a selection *directly* differentiating a comparatively few characters.

If selection has changed a race from a condition A to a condition B, it becomes of much interest to determine the nature of the selective death-rate by which the process has been carried on, and it is found that this death-rate as represented in the surface of survival rates enables us to distinguish two kinds of selection, termed in the memoir positive and negative selection. In the first case, a race is modified, because the nearer its members are to having their organs with a certain system of values, the better fitted they are to survive; in the second case, the nearer the individuals are to this system the less fitted they

are to survive. There will usually be in this second case, not a single system, but an indefinite number of systems which would equally well fit individuals to survive; in the first case, on the other hand, there are an indefinite number of systems which equally unfit their owners for surviving. This distinction seems of considerable interest.

For example, to select from the French race a race in femur and humerus like the Aino, we should have to proceed by a positive selection; but to select from the Aino a race like the French, we should have to proceed by a negative selection. To get 1000 Aino we should have to select for these two organs alone out of some 6,000,000 Frenchmen, but to get 1000 Frenchmen from the Aino we must select from about a billion of the latter. Thus we are to some extent able to appreciate the stringency of the selection, which even lasting through long ages, and introducing continuous reproduction, would be needful to enable us to pass in the case of only two organs from one race to the other. Another point brought out by the surface of survival-rates is the fact that the fittest to survive are usually not the most frequent survivors.

It will be seen that the memoir opens up a novel field of investigation, but one so wide that the theory of it must be limited by close contact with what is needful for the purposes of evolution. We want measurements on the local races of animals to guide us; at present we know scarcely in any one case whether differentiation has taken place by *direct* selection of few or of many organs. When once such measurements are forthcoming we shall have firmer ground to go upon, and the processes of the present memoir seem to suggest how in the future we shall be able to link together quantitatively local races, and possibly at a more remote date obtain quantitative conceptions of the stages of evolutionary descent itself.

January 30.—"The Specific Volumes of Oxygen and Nitrogen Vapour at the Boiling-point of Oxygen." By James Dewar, M.A., D.Sc., LL.D., F.R.S.

In a paper on "The Boiling-point of Liquid Hydrogen determined by Hydrogen and Helium Gas Thermometers" the author pointed out that a constant-volume gas-thermometer filled with oxygen gas, having a pressure at 0° C. of about 800 mm., gave a very accurate value of the boiling-point of liquid oxygen. As it seemed advisable to confirm this result indirectly, an attempt was made to determine the vapour density of oxygen at its boiling-point by direct weighing, the intention being, if the experimental results proved at all encouraging, to repeat the work on a larger scale and with greater precautions. As at present there is no likelihood of the more accurate determinations being made, the results of the preliminary inquiry are presented to the Society. They give in any case, with considerable accuracy, the specific volumes which have never been directly determined.

In order to obviate any question of the buoyancy of the air, two flasks A and B of as nearly as possible the same air displacement were counterpoised on an Œrtling balance. The B flask remained permanently on one scale of the balance during all the weighings, while the A flask was weighed, either exhausted or filled with oxygen (or nitrogen), in various circumstances according as the experiments required.

As the intention was not only to ascertain the density of oxygen and nitrogen at their respective boiling-points under atmospheric pressure, but also under diminished pressure, experiments were made with nitrogen at ordinary temperatures and at pressures varying from about one-sixth of an atmosphere to ordinary pressures, in order to find the range of variation in the results with the 316 c.c. flask to be used in the subsequent low-temperature experiments.

Experiments with nitrogen give a mean value of 1·260 grammes, at standard temperature and pressure, as the weight of a litre of the gas. This is about a quarter per cent. higher than the accepted value of 1·257. The extreme variation in the individual experiments is about half a per cent. The average value of the results under about one-third of an atmosphere is 1·266 grammes, the tendency under the low pressures being to make the density half a per cent. higher. Considering that in the actual low-temperature experiments the mass of gas to be weighed would be at least three times greater, it was inferred that in spite of difficulties of manipulation and corrections, the results might be anticipated to lie within a half per cent. of the true value.

The mean weight, given by six experiments, of one litre of oxygen vapour at 760 mm. and 90°·5 absolute was found to be 4·420 grammes, and the specific volume 226·25 c.c. If the first two experiments are eliminated on the assumption that the proper equilibrium of temperature had not been attained, the average weight per litre would become 4·428 grammes, and the specific volume 225·82.

Taking Regnault's density of oxygen at 0° and 760 mm., the density at 90°·5 in the ordinary way would be 0·0043137, and the specific volume 231·82 c.c. Thus the volume given by the ordinary gaseous laws is 1·0246 times the average observed volume; or we may put it that pv is diminished at the boiling-point of oxygen by 2·46 per cent. Again, while the ratio of the absolute temperatures is 3·017, the ratio of the densities is 3·091.

Further experiments were made on oxygen vapour at 90°·5 and under reduced pressures. If the first three experiments are averaged (the pressures being close together), the weight of a litre of oxygen at 90°·5 absolute under a pressure of 282·5 mm. would be 1·5982 grammes. The ratio of this density to the value previously found for one atmosphere pressure, viz. 4·42 grammes, is 2·765, and the ratio of the pressures is 2·690. It appears that the ratio of the change of density of the vapour of oxygen at 90°·5 absolute, under variable pressure, is greater than the ratio of the change of pressure. It is clear, however, that it would be necessary to work upon a larger scale in order to get satisfactory vapour densities at low temperatures under pressures below that of the atmosphere.

Observations were made on the density of nitrogen vapour at the boiling-points of liquid oxygen and liquid air respectively.

Two experiments were made with liquid oxygen taken to be at temperature 90°·5 absolute. Four experiments were made in one and the same sample of liquid air, with rising temperature. The first two experiments made with liquid oxygen give a ratio of the nitrogen densities from the author's own values of 3·088, the absolute temperature ratio being 3·017, his values for the ratio of the oxygen densities for the same range of temperature being 3·091 as previously deduced. It may be safely assumed that if the density of nitrogen were observed at its boiling-point it would deviate as much from the ordinary gaseous laws as oxygen. Further, the specific volume of nitrogen at its boiling-point of 78° absolute would from the above formula be 221·3 as compared with 226·2, the similar value found for oxygen.

The general inference to be drawn from these preliminary experiments is that trustworthy vapour densities may be determined at very low temperatures. There seems to be no reason why the vapour density of hydrogen at its boiling-point should not be accurately ascertained; only, as in this case the internal pressure in the weighing flask would amount to nearly fifteen atmospheres, it would be advisable to construct the flask of some metal or alloy. A flask of the size used in the oxygen experiments filled with the vapour of hydrogen at its boiling-point would be equivalent in weight to between four and five litres of hydrogen at the ordinary temperature and pressure, and such an amount of material ought to give density results at the boiling-point of hydrogen of considerable exactness, notwithstanding the great manipulative difficulties that would necessarily be involved in the execution of such a determination at 21° absolute.

Physical Society, February 14.—Annual General Meeting.—Mr. T. H. Blakesley, vice-president, in the chair.—Prof. S. P. Thompson, F.R.S., was re-elected president. Prof. S. P. Langley and Prof. H. A. Lorentz were elected honorary fellows to fill the vacancies caused by the deaths of Prof. Rowland and Dr. Koenig. The president of the German Physical Society was elected an *ex-officio* fellow of the Society.—The secretary then read the president's address. It commenced by giving some particulars of the life and work of Rowland, Koenig, Langley and Lorentz. On January 11 a telegram was sent, in the name of the Society, to Prof. Hittorf congratulating him upon the jubilee of the professoriate. The work of translation, revision and production of an English version of Gilbert's "De Magnete" has been completed, and a copy of the book presented to the Society by the president. The remainder of the address dealt with the refusal of the law of this country to recognise as valid matter for the granting of letters patent anything which may have been brought before any of the learned or scientific societies. In the United States a man may appeal to the fact of his having read such a paper in proof of his subsequent claim to receive a valid patent for his

nvention. The law in this country works very inequitably. As examples, the invention of the microphone by the late Prof. Hughes, the president's invention of the "astigometer" and the invention of wireless telegraphy by Prof. Lodge were given. —An ordinary meeting of the Society was then held, at which Mr. Littlewood exhibited an Attwood's machine.—The Society then adjourned until February 28.

Chemical Society, February 6.—Dr. Armstrong, F.R.S., in the chair.—An investigation into the composition of brittle platinum, by Prof. Hartley, F.R.S. Platinum points repeatedly heated in the course of dental practice become very brittle, owing, the author believes, to the presence of minute quantities of carbon and phosphorus, although such impurities could not be definitely detected.—Conversion of 1-hydroxycamphene into β-halogen derivatives of camphor, by Dr. M. O. Forster. The author finds that his supposed "enolic" form of camphor is really 1-hydroxycamphene, and has studied the action of halogens upon it, so obtaining the various β-substituted camphors.—Tetrazoline, ii., by Messrs. Ruhemann and Stapleton. The action of methyl iodide upon this substance gives rise to several derivatives of unknown relation to tetrazoline.—The solubilities of the calcium salts of the lower fatty acids, by Dr. Lumsden. The author has investigated the influence of temperature upon the solubilities of these salts, and has shown that, with the exception of the formate, they decrease in solubility with increase of temperature. The salts of the normal acids show increasing solubility as the series is ascended, but are less soluble than the corresponding *iso*-salts.—The equilibrium between a solid and its saturated solution at various temperatures, by Dr. Lumsden. The solubility of a substance is affected by three factors—the solution pressure of the dissolved molecules, the thermal energy of dissociation of the substance, and the affinity, if any, of solvent and solute. The solubility curve (temperature, weight of substance) may be regarded as expressing a series of equilibria between these influences at the various temperatures included in the curve, and from this point of view it is shown that the solubility curves of calcium salts are not abnormal.—On the union of hydrogen and chlorine, iv., by Messrs. Mellor and Anderson. The momentary expansion in mixtures of these gases, brought about by exposure to a brilliant light, is shown to be associated with their combination and, it is suggested, is caused by some disturbance resulting from the latter.—The influence of temperature on association in benzene solution and the value of the molecular rise of boiling-point for benzene at different temperatures, by Dr. W. R. Innes. With increase of temperature, the complex molecules of phenanthrene, benzophenone, benzil, &c., produced in their solutions in benzene, become simpler up to 80°; beyond that point certain (at present) unexplained anomalies appear.—The magnetic rotation of ring compounds, camphor, limonene, carvene, pinene and some of their derivatives, by Dr. W. H. Perkin, sen. It is shown that the observed rotations of these substances agree closely with those calculated from the formulæ generally assigned to them.—Note on the constitution of certain organic nitrates, by Messrs. Marshall and Wigner. The authors express dissent from the view of Vignon and Gerin that mannitol hexanitrate contains a substituted aldehyde group, since the reducing action of the substance can be explained without such an assumption, and, moreover, the amount of nitrous acid formed on hydrolysis does not accord with the structure suggested.—Resolution of trimethylhydrindonium hydroxide into its optically active constituents, by Prof. F. S. Kipping, F.R.S. The deracemisation of this substance has been brought about by conversion into a salt of *d*-bromocamphorsulphonic acid and crystallisation from chloroform and acetic ether when the salt of the dextro-base separates first.—Resolution of methylbenzylacetic acid into its optical isomerides, by Prof. F. S. Kipping, F.R.S. Crystallisation of the quinine salt of the racemic form of this acid leads to the separation of the alkaloidal salt of the dextro-acid in the first fractions.—*d*-Methylhydrindone, by Prof. F. S. Kipping, F.R.S. This substance was obtained from the chloride of dimethylbenzylacetic acid by interaction with aluminium chloride. It rapidly racemises when heated, probably as the result of conversion into the 'enolic' form. It reacts with hydroxylamine, phenylhydrazone and semicarbazide, furnishing the various ketonic derivatives.—Optically active methylbenzylacetic acid, by Dr. Lapworth and Mr. Lenton. A repetition of the work described by Dr. Kipping in part ii.

Mineralogical Society, February 4.—Dr. Hugo Müller, president, in the chair.—Messrs. G. T. Prior and L. J. Spencer contributed a paper on the hornsilvers. They described specimens of silver haloid containing all the three halogens, chlorine, bromine and iodine, in large amount, and showed by quantitative analyses that in these holohedral cubic "iodiferous embolites" the chloride, bromide and iodide of silver could enter into isomorphous combination in very varying proportions besides the particular one found by Lasaulx in iodobromite; fusion experiments indicated that the limiting amount of silver iodide which could enter into such isomorphous combination was reached for mixtures containing the three halogens in equal atomic proportions. As the result of the investigation, the authors proposed to include all the holohedral cubic silver haloids under the common group name of hornsilver or cerargyrite, and to use the names "chlorargyrite," "bromargyrite," "embolite" and "iodiferous embolite" to indicate subspecies depending on variations in the proportions of chloride, bromide and iodide.—Mr. G. T. Prior described specimens of kilbrickenite contained in the museum of the Mining School at Camborne, Cornwall; the result of an analysis, combined with an examination of the physical characters, was to prove the identity of kilbrickenite with geocronite. He also gave the results of analyses of miersite ($4AgI.CuI$), of marshite (CuI) and of peculiar crystals of copper-pyrites simulating cubic symmetry.—Messrs. G. T. Prior and A. K. Coomára-Swámy gave an account of the mode of occurrence and characters of "serendibite," a new boro-silicate from Ceylon. This new mineral, which is of a beautiful blue colour, was discovered by Mr. Coomára-Swámy in intimate association with diopside in narrow contact zones between an acid, moonstone-bearing granulite and limestone which occur in alternating bands at Gangapiliya, twelve miles east of Kandy; no distinct crystals could be isolated, but examination of thin slices of the rock showed the mineral to be biaxial and probably triclinic; it was very pleochroic, from colourless to deep indigo-blue, and almost invariably showed a remarkable repeated twinning on as intimate a scale as the albite twinning of a plagioclastic felspar; the double-refraction is weak, but the refraction nearly as high as diopside; the hardness is about 7, the specific gravity 3·42; no cleavage was observed; it is infusible and is only slightly attacked by acids. Analysis showed the mineral to be a complex and very basic borosilicate of alumina, lime, magnesia and iron with small amounts of alkalis including lithia.—Prof. H. A. Miers exhibited three-colour collotype prints of the interference figures of crystals. These were obtained by photographing the figures through colour screens by means of a large Newton polariscope. Some of the prints reproduced with considerable success the colours and the symmetry of the original figures. The work has been executed at the Oxford University Press. He further exhibited calcite twins of a rare type from a new locality in Somersetshire, and also some crystalline gold nuggets from Klondyke.

PARIS.

Academy of Sciences, February 10.—M. Bouquet de la Grye in the chair.—On a very powerful specific treatment for malaria, by M. Armand Gautier. A detailed account of the cure of nine cases of malarial fever by the injection of sodium methylarsenate. These cases, which had all proved refractory to high doses of quinine, were, with the exception of two, immediately cured by the injection of a single dose of the methylarsenate. The remaining two cases were successfully treated with a second injection.—On the crystallisation of chromium sesquioxide, by M. Alfred Ditte. The crystallisation of chromium oxide during the calcination of a bichromate with common salt is shown to be due to the properties of sodium chlorochromate, and is in no way influenced by the solubility of the oxide in the alkaline chloride.—The determination of the exact trajectory of aërostats with respect to the soil, by M. H. Deslandres. A curve of the trajectory of the aërostat of M. Dumont on the ascent of October 19 is given and compared with the curve previously given by M. Armengaud. The two curves differ from each other considerably, the author pointing out that his own, which is deduced by a photographic method, is more likely to be accurate than that of M. Armengaud.—Radioconductors with a single contact, by M. Édouard Branly. The author has followed up some of his earlier experiments on radioconductors of one contact only, and describes two or three types which have proved very sensitive. The combination of a superficially oxidised metal with a highly polished metal has proved to be the most trustworthy,

giving the greatest variation of resistance when exposed to the Hertzian waves.—The application of thermal galvanometers to the study of electric waves, by M. L. de Broglie.—The tubes of force of the magnetic field rendered visible by means of the kathode rays, by M. H. Pellat. In an intense magnetic field, the bundle of kathode rays which escapes from a kathode in the form of a plateau corresponds exactly to the tube of magnetic force having for its base the surface of the kathode.—On the condensation of true acetylenic hydrocarbons with aldehydes: the synthesis of secondary acetylene alcohols, by MM. Ch. Moureu and H. Desmots. The sodium derivatives of the acetylene hydrocarbon react readily with aldehydes in ethereal solution at -5° C. The method is perfectly general, and ten new alcohols of this type are described.—On some iodophenols, by M. P. Brenans.—The action of crystallised arsenic acid upon pinene, by M. P. Genvresse. Arsenic acid does not act as an oxidising agent towards pinene as was expected, the principal products being either pinene possessing a different smell from the original or a terpinene, according to the proportion of arsenic acid employed.—The vascularisation of the suprarenal bodies in the dogfish, by M. Ed. Grynfeltt.—On *Menabea venenata* the roots of which furnish the *Tanghin de Menabe*, or *Sakalaves*, the poison of the ordeal, also called *Kissoumpa* or *Kimanga* in Madagascar, by M. Ed. Heckel.—On the effects of commensalism of an *Amylomyces* and of a *Micrococcus*, by M. Paul Vuillemin. The association of *Mucor rouxianus* and a *Micrococcus* feeding on sugar allows of the development of the bacterium on potato.—The discovery of a new horizon of a lacustral fossiliferous limestone interposed between the Miocenes of Ariege, by M. G. Vasseur.—On the alkaline granite of Filfila, Algiers, by M. Pierre Termier.—A new method of local anæsthesia in dentistry, by MM. L. R. Regnier and Henry Didsbury. The researches of M. d'Arsonval on the anæsthetic effects produced by currents of high frequency and high intensity have been applied with success to the purposes of practical dentistry.—An apparatus for the blind, by M. Dussaud.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part ii., 1902, contains the following memoirs communicated to the Society:—

July 20, 1901.—A. von Koenen: on the correlation of the North-German Lower Chalk.—J. Orth: contributions from the Göttingen Pathological Institute: (*a*) ætiology of caseous pneumonia; (*b*) tubal gravidity; (*c*) the lower jaw in so-called agnathia; (*d*) pseudo-tuberculosis; (*e*) soft cutaneous nævi; (*f*) epidermal ingrowths in cancer; (*g*) pericardial cicatrices; (*h*) renal degeneration after cœliotomy; (*i*) the testicular elastic tissue in tuberculosis and syphilis; (*j*) angiomatous changes in the liver after poisoning by coumarin.—J. Orth: histology and ætiology of pulmonary phthisis.

November 8, 1901.—W. Kaufmann: electric and magnetic deflexion of the Becquerel rays, and the apparent mass of electrons.—A. Brill: on the representation of an algebraic tortuous curve by one equation.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 20.

ROYAL SOCIETY, at 4.30.—On Pure Cultures of a Uredine *Puccinia dispersa* (Erikss): Prof. H. M. Ward, F.R.S.—On the Physics and Physiology of Protoplasmic Streaming in Plants: Dr. A. J. Ewart.—On a Pair of Ciliated Grooves in the Brain of the Ammocœte, apparently serving to promote the Circulation of the Fluid in the Brain-Cavity: Prof. A. Dendy.—On the Interpretation of Photographic Records of the Response of Nerve obtained with the Capillary Electrometer: G. J. Burch, F.R.S.—Note on the Anomalous Dispersion of Sodium Vapour: Prof. W. H. Julius.

LINNEAN SOCIETY, at 8.—(1) On some Gasteropoda (*Limnotrochus* and *Chitra*) from Lake Tanganyika, with the Description of a New Genus; (2) On the Nyassa Vivipara and its Relationship to Neothauma: Miss L. Digby.—On the Fruit of *Melocarina bambusoides*, an Exalbuminous Grass: Dr. A. Stapf.—On a West Indian Sea Anemone, *Bunodeopsis globulifera*: Dr. J. E. Duerden.

FRIDAY, FEBRUARY 21.

ROYAL INSTITUTION, at 9.—Musical and Talking Electric Arcs: W. Duddell.

BRITISH GEOGRAPHY.

Britain and the British Seas. By H. J. Mackinder, M.A., Reader in Geography in the University of Oxford. Pp. xvi + 378. (London: William Heinemann, 1902.)

THIS important contribution to geographical literature is, we believe, the first effort to present a complete geographical description of the British Isles in accordance with modern views, complete, however, rather in comprehensiveness of scope than in exhaustiveness of detail. The work strikes us as literature—clothing in dignified and continuous form the theories and conclusions of many workers—rather than science, which in the existing state of geographical knowledge demands more critical treatment of controversial matters and more direct contact with original data. The author excels in broad generalisations, and he has a happy knack of setting essential facts in striking lights, so that they are forced on the attention of the reader and remain fixed in his memory. It is impossible, of course, that any one man could be an independent authority on all the subjects which have to be dealt with in a geographical description; but Mr. Mackinder has got up his case so thoroughly that it is only by the smoother running of his chariot wheels where he enters on the domain of human, and especially of historical, affairs that we are led to suspect which are his most familiar studies.

A striking merit in the arrangement of the book, and it is a great one, is that no doubt can arise as to its purpose and plan. The development of the argument is preceded by an opening statement and clenched by a formal array of numbered paragraphs setting forth what is claimed as having been established. Unlike many books which are geographical in intention, this one is consistent throughout, tracing an unbroken chain of causation from the earliest hypothesis as to the existence of ancient land in the geological past to the latest forecast of thought in the political future. The chain is not equally strong in all its parts, and its extremities pass into regions of gloom which some faith is required to believe illumined.

The first chapter treats of the position of the British Islands (which we are glad to see gathered under the one word Britain), showing how in classical times they were at the end of the habitable world, with only ocean and ice beyond, while now they lie in the very centre. Mr. Mackinder speaks of the ice drift in the East Greenland current as "the physical boundary of mediæval Europe"; yet there is some evidence to show that the western voyages of the Norsemen met but slight obstruction from the ice, and the vanished settlements of East Greenland point to a comparatively recent increase in the severity of the climate. That the trade-winds blow over the Sahara we should not like to affirm, though Mr. Mackinder is doubtless correct in taking the southern boundary of the mediæval world of Europe as the Trades and the desert. But when the reign of terror of the half-known—cold and heat and the vacant spaces of ocean—was shattered by the voyagers from Iberia, Britain swung into the centre of the land hemisphere:—

"Seen thus in relation to earlier and to later history, Britain is possessed of two geographical qualities, complementary rather than antagonistic: insularity and universality."

The nature of the insularity is investigated in a chapter on the British seas, contrasting the Ocean with the Narrow Seas towards Teutonic Europe and the Narrower Seas towards France; and the remarkable coincidence that the narrowest channel, which separates Kent from the continent, lies opposite the terminus of the great Teutonic-Romance linguistic frontier of Europe is treated with a masterly completeness.

The movement of the waters, tidal and circulatory, receives a chapter to itself, and then on p. 46 the serious part of the book begins, and the general reader will meet with his first check, for he must enter on a hundred pages of fairly stiff geology. This is not the geology of the text-books; formations are scarcely referred to, and there is absolutely nothing of palæontology. It is a restatement, and in some particulars an extension, of the history of the rifted crust-blocks of Suess and the system of coastal-plain formation and river-development with which the name of W. M. Davis is usually associated. The theories are boldly and skilfully employed, and in their light the building of the British Isles stands forth with startling clearness; the author might have seen it all. We question whether any geologist intimately acquainted with the details and the infinite uncertainties of one department of his science would have dared to compress the history of the past into the few clear-cut episodes which are here presented in a manner which wins our admiration even if it fails to gain our entire confidence. We may quote part of the author's summary, bearing in mind that a much fuller statement is given in the pages:—

". . . . The fringe of headlands along the west coast of Scotland, and the lie of Glenmore and the Rift Valley, betoken a south-westerly rock-graining, to be interpreted as the wreck of a Caledonian mountain range, which once crossed the site of the North Sea.

"But the existing hills have not been shaped from the Caledonian peaks by uninterrupted erosion. The general equivalence of the higher summits, and the transverse, southerly trend of the consequent valleys where they breach the ridges, can only be explained by the interpolation of an epoch during which the mountains were reduced to a basal plain. Thence followed a fresh cycle of denudation when the plain was raised to a grained plateau spreading back from the British Uplands towards Iceland and Greenland.

"By what process the plateau of Atlantis collapsed and the uplands of its south-eastward face were transferred to developing Europe, may be imagined from the form of the ocean bed. Two abysmal pits, Atlantic and Arctic, gradually encroached upon the land until they merged across it, and the divide between them became the submarine isthmus known as the Scoto-Icelandic Rise. The southward belt of median uplands in Britain—Highland, Central and Cambrian—is in prolongation of this rise, and no doubt due to the same terrestrial stresses.

"Britain was differentiated from the rest of the slope of Atlantis by the formation of proto-Britain in advance of the Caledonian shore line. Against the resistance of this salient block the Hercynian pressures crumpled the strata into northward and westward folds, and these,

together with the earlier south-westward features, have determined the triangular outline of Britain.

"By their intersection the Hercynian axes also shaped the coal-basins of Great Britain; but Ireland, under the lee of proto-Britain, suffered less disturbance and has therefore been stripped of most of its coal, which was thus unsheltered from denudation.

"The posthumous Hercynian uplift which raised the Wealden fold, produced an organic connection between the Kentish promontory and the Rhine-Seine divide, and the English plain of softer rocks is, therefore, a segment of the coastal plain of Atlantis, preserved and brought into European relations by events of late geological date."

Here we have a kinematograph picture, with scarcely any flickering. Something like this has most probably happened; but few readers will, we fear, be in a position to understand that the events referred to can only be felt out in dimmest outline by very uncertain inferential methods, which in various hands have given different results. Mr. Mackinder goes on to connect the process of geotectonic history with human history, but the connection strikes us as in large part metaphysical if not fanciful. Unquestionably the relief of the land, and the climate—which, by the way, is treated with charming simplicity and fidelity to verifiable facts—exercise a powerful directive influence on the distribution of life and on the course of human history, and undoubtedly the land owes its relief to the processes of geological history; but we contend that no matter what the precise course of that history may have been, the surface-forms once produced, no matter how, would have exercised the same functions in controlling distribution. Whether a mountain is folded up by the puckering of a plain, or cut out by the carving of surrounding valleys, or poured forth as lava, or piled up as ashes, if it has assumed a given form and is covered by a particular soil its action upon life and man will be identical.

Our argument is that the same final result might be the outcome of any one of a number of causes; and that the latest Earth-movements, though slight, are more potent in their geographical aspect than early movements of far greater magnitude. In fact, we believe that actual landforms, not the processes of their formation, are the real elements of geography.

Such a book as this ought not to be criticised in detail, but judged broadly according to its plan, its scope and its methods. Still, we cannot help noticing some inequalities of treatment which exercise a warping influence on the framework of the argument. It is, from the geographer's point of view, a trifle of no importance that the Glacial and post-Glacial periods are classed as Tertiary, and it may be that the author is right in saying that Ramsay's views as to the origin of lakes by ice-action are now gaining ground—though we should like to hear him propound this theorem at a meeting of the Geological Society—but he is certainly wrong in dealing so briefly with the Glacial episode as a whole. A geographer could not, we should have thought, consider the parts of Britain north of the Thames and Bristol Channel without recognising how profoundly the whole face of Nature has been modified by the power of ice. The map of the solid geology gives but a poor idea of the actual surface of the land, the contours of which are due over large areas to boulder clay alone; and the courses of many rivers have suffered revolutions in the Ice-age which must entirely mask the consequences, the subsequences, nay even the obsequences of the secular advance of the "geographical cycle." We feel sure that even though Mr. Mackinder's geomorphology may be criticised and possibly confuted in parts, the latter and more purely geographical part of his work will stand unshaken.

This latter part includes a chapter on racial geography and another on historical geography which are models of clear and brilliant exposition. They will not, perhaps, give pleasure to the devotees of Celticism, who may be inclined to demand proofs for a classification including "the catholic Irishman essentially a pre-Celt . . . , the Highlander pre-Celtic and mercurial . . . , the Welshman with a strong pre-Celtic infusion." The different regions of the country are considered under the heads of Metropolitan England, Industrial England, Scotland and Ireland, showing how the dominant facts of relief, structure and climate control the life of the people, the routes along which they travel and the sites in which they settle. Here there is nothing of the gazetteer or the guide-book; no attempt is made to enumerate all important towns, and throughout the references to scenery are surprisingly scanty; but the reader feels that he is being initiated into some of the secret springs of history. Two chapters follow impressing these views still more strongly; they treat of strategic and economic geography, and the latter in particular shows much care and completeness. It is curious, however, to notice that while the power of the tides, which are still unharnessed, is spoken of in almost poetical terms as a possible substitute for coal, the water power of the land, better understood and more utilised as it already is, has hardly any attention directed to it. Yet even now we find water power successfully competing with coal in the supply of electrical energy for extensive manufactures, and its vast potentialities are not unknown to practical men. A short chapter on Imperial Britain illustrates some of the lessons which the geographer may teach, or at least offer to teach, the politician; and a summary and conclusion recapitulate the argument.

There is, in our opinion, too much hypothesis in the book, and the grounds for many of the conclusions are inadequately stated. Rival interpretations are not set one against the other, and the reader coming fresh to the subject is apt to form an exaggerated opinion of the certainty of some historical processes, both geological and human. But, on the other hand, we have here an attempt to show how the worlds of Nature and Man may very justly be conceived as knit together, and it is extremely probable that such a book, written with more boldness than most scientific men could display, will bring home some aspects of scientific thought to minds shut against ordinary and clumsier exposition. The book is eminently deserving of study, and it is sure to suggest many new and valuable ideas both to novices and experts.

The numerous illustrations are restricted to maps and diagrams, and we have never seen sketch-maps used to better purpose, although a few betray in their weak outlines a draughtsman not yet fully alive to the precautions required in drawing for photographic reduction.

THE BOOK OF THE DEAD.

The Book of the Dead: an English Translation of the Chapters, Hymns, &c., of the Theban Recension, with Introduction, Notes, &c., and with Four Hundred and Twenty Vignettes. By E. A. Wallis Budge, M.A. Litt.D., D.Lit. In three volumes. Pp. xcvi + viii + iii + 702. Vols. vi.–viii. of the series "Books on Egypt and Chaldæa." (London: Kegan Paul and Co., Ltd., 1901.)

READERS of NATURE will remember that nearly three years ago we noticed the appearance of a work, published by the trustees of the British Museum, in which facsimiles were given of the Egyptian papyri of Hunefer, Ȧnhai, Kerāsher and Netchemet, together with the text of the papyrus of Nu, the whole work being edited and annotated or translated by Dr. Wallis Budge, the keeper of our national collection of Oriental antiquities. As we pointed out at the time, this monumental work completed the series of facsimiles of papyri of the "Book of the Dead," which the trustees of the Museum have published at intervals during the last eighteen years, and by its appearance furnished scholars with a remarkable series of papyri of all periods for the study of the funereal literature of the ancient Egyptians. The great amount of new material published in this series of volumes rendered still more apparent the want of a complete edition of the text of the "Book of the Dead," which has been increasingly felt since the appearance in 1886 of M. Naville's "Das Todtenbuch der Ægypter," in which were given the various chapters from the different papyri then available.

The want was supplied by Dr. Budge, who, under the title "Chapters of Coming Forth by Day," published a complete edition of the text, based upon all known papyri, together with a translation and a full vocabulary to the hieroglyphic texts. This bulky work in three volumes appealed in the main to scholars, while its price placed it beyond the reach of many whose interest in the "Book of the Dead" stopped short of the acquisition of its complete hieroglyphic text. It was in answer to numerous requests from this latter class of readers, as we learn from the preface to the volumes before us, that the publishers decided to include Dr. Budge's English translation in their series of little "Books on Egypt and Chaldæa." The books under review, however, contain no mere reprint of a portion of the former work. Careful revision, based on a comparison of the original documents, constitutes the translation a new edition of the English rendering; and while from the introduction the general reader may gain a knowledge of the history, object and contents of the "Book of the Dead," he need not be puzzled by obscure references or phrases in the translation if he consults the many explanatory notes which have been added to this edition. We shall in the main confine ourselves to the new material thus presented, and shall refer in some detail to the remarkable series of vignettes here published for the first time; before doing so, however, it will be necessary to sketch briefly the nature of the religious texts which are here translated.

The title "Book of the Dead" is now almost a household word, and it is never likely to be changed either for the Egyptian title "Chapters of Coming Forth by Day," or for any conventional description of its contents. That it is unsatisfactory Dr. Budge admits, for the "Book of the Dead" is not a book in the strict sense, that is to say, it is not a fixed composition the different copies of which vary but slightly. But the title is short, it is sanctioned by the authority of Champollion and Lepsius, and the texts so described certainly concern the dead; moreover, it is far preferable to the titles "Ritual of the Dead" and "Funeral Ritual," which have been suggested as substitutes. The great body of Egyptian religious texts which bear this title have a long and varied history; with their origin buried in the remote past, they grew by accretion throughout the whole life of the Egyptian nation, and their contents reflect the beliefs and opinions of many different and conflicting schools of thought. But, as Dr. Budge points out, every chapter or section that has yet been recovered has a link which connects it with the rest; however barbarous or however exalted may be the character of the beliefs a chapter embodies, it shares a common object with the others—that of benefiting in some way the deceased. And it is this common object which constitutes the claim of the "Book of the Dead" to be the great national religious composition of ancient Egypt. In what way its chapters were to benefit the deceased may best be described in Dr. Budge's own summary:—

> "They were intended to give him the power to have and to enjoy life everlasting, to give him everything he required in the life beyond the grave, to ensure his victory over his foes, to procure for him the power of going whithersoever he pleased and when and how he pleased, to preserve the mummy intact, and finally to enable his soul to enter into the bark of Rā or into whatever abode of the blessed had been conceived of by him."

The recently discovered graves of some of the indigenous inhabitants of Egypt show that two distinct methods of burial were practised at that early period, and probably by two distinct peoples. By the one the dead were partially burnt, and afterwards the skull and bones were placed in a shallow pit; by the other the body was buried either whole or after it had been dismembered. Both peoples oriented the dead in the same direction and both made offerings to the dead. It is clear, therefore, that both peoples had a clear perception of a future life, while the traces of bitumen discovered by Dr. Fouquet upon some of the buried bodies suggest that these early inhabitants of Egypt, like their later descendants, believed that the welfare of the deceased depended upon the preservation of their earthly remains. Although no inscriptions have been found in these early graves, there is much that lends colour to Dr. Budge's suggestion that the origin of the "Book of the Dead" may be traced to the prayers and formulæ recited during burial at this early period in order to preserve the dead body from the attacks of wild animals and from decay. The earliest written version of the "Book of the Dead" occurs upon the walls of the chambers and passages in the pyramids of the kings of the fifth and sixth dynasties at Saḳḳâra, and it does not, therefore, date from an earlier period than B.C. 3500; but the mistakes and misunderstandings of the scribes who engraved these texts prove that many of the formulæ were even then unintelligible

by reason of their antiquity; moreover, the beasts and creatures, which the prayers and spells were intended to frighten away from the dead man, belong to the period when forests clothed the banks of the Nile in Egypt and river monsters of all kinds abounded which are now only to be found on the upper reaches of the Blue Nile and near the Great Lakes.

In his introduction, Dr. Budge has brought together some exceedingly interesting evidence that parts of the "Book of the Dead" were in general use even before the period of the kings of the first dynasty; but what concerns us here is, not the early history of the book, but the traces which its early history has left upon it, and which have been retained even in its most perfect and complete form, the so-called "Theban version," which is found written upon papyri in tombs of the eighteenth, nineteenth and twentieth dynasties. The Egyptian was conservative to the backbone, and to this conservatism the anthropologist and the scientific student of religion are much indebted; for as he advanced in his religious beliefs and conceptions, he did not discard all traces of his earlier and more primitive state, but along with the profession of his more spiritual faith he jealously clung to and retained the earlier spells and formulæ which had long ceased to apply to his own condition of life. It is thus possible in the "Book of the Dead" to trace the semi-barbarous North-African element contending with more moral and spiritual beliefs, the rise of which Dr. Budge traces to the presence of some Proto-Asiatic element in the composition of the Egyptian race. The space at our disposal does not admit of our treating this fascinating subject at greater length, and for a more detailed discussion we must refer the reader to Dr. Budge's introduction.

We have already made a brief reference to one of the most striking characteristics of this latest edition of the "Book of the Dead"—the beautiful series of outline blocks with which the chapters are illustrated. The ancient Egyptian scribes and artists used to add to the separate chapters or sections of the work vignettes, or pictures, intended to illustrate their general contents and also to have in themselves a magical effect upon the destinies of the deceased; and these pictures are often of considerable assistance in the interpretation of the texts to which they refer. Dr. Budge has selected the vignettes from the best papyri, and where the designs vary in different papyri he has given more than one version; as interesting examples of varying treatment we may refer to the three vignettes illustrating the "Weighing of the Heart" (p. 31 *f.*), the numerous illustrations to chapter xvii. and the curious variant to the vignettes of chapter xxxvi. This last chapter ensures the driving away of the insect called *Āpshait*, which Dr. Budge identifies with

"the beetle which is often found crushed between the bandages of poorly made mummies or even inside the body itself, where it has forced its way in search of food."

Thus, in most vignettes to this chapter the deceased is represented spearing a beetle, as in those illustrated on p. 161; but in the vignette on p. 162 the deceased is portrayed spearing a pig and not a beetle, which the translator ingeniously explains as due to the scribe having confused the proper name *Āpshait* with *shaā*, the word for "pig." The vignettes throughout the volume have been faithfully drawn from the originals in bold, clear outline, and, apart from the light they throw upon the text, they form in themselves a beautiful series of examples of Egyptian design and draughtsmanship.

In conclusion, we may say that we heartily endorse the remarks which are made in the preface with regard to the fashion that has grown up among certain writers on Egyptology during the last few years, who decry the "Book of the Dead" and announce as a great discovery that parts of its text are corrupt. But, as Dr. Budge remarks, this fact has been well known to Egyptologists for the last fifty years, and is, moreover, a characteristic shared by every great national religious composition which is handed down first by oral tradition and secondly by copies which are multiplied by professional scribes.

"The more the 'Book of the Dead' is read and examined," he adds, "the better chance there is of its difficult allusions being explained and its dark passages made clear, and this much-to-be-desired result can only be brought about by the study, and not by the condemnation, of its texts."

To this end no other scholar has contributed so much as Dr. Budge himself, and his latest efforts, embodied in the volumes before us, will place a rich store of material within the reach of the humblest worker in the great field of the comparative study of religions.

FOSSIL FISHES IN THE BRITISH MUSEUM.

Catalogue of Fossil Fishes in the British Museum (Natural History). Part iv. By Arthur Smith Woodward, LL.D., F.R.S., F.G.S. Pp. xxxviii + 636, 22 figures, 16 plates. (London: Printed by order of the Trustees, 1901.)

THE fourth volume of this great work, which has just appeared after an interval of six years since the publication of the third volume, completes the account of the unrivalled collection of fossil fishes preserved in the national museum, to which the author has devoted so much attention during the twenty years which have preceded his appointment to the post of keeper of the geological department, on the retirement of Dr. Henry Woodward. The issue of this volume, dealing entirely with the Teleosts, was eagerly awaited, not only by palæontologists, but also by all students of fishes, as great hopes were entertained that a revised arrangement of the bony fishes, the preponderating element in the recent fauna, would result in very considerable progress in our understanding of the inter-relations of the components of this difficult group.

If the feeling of joy be mixed with some disappointment at so many problems of classification remaining unsolved, the fault rests entirely with the nature of the material with which Dr. Woodward has had to deal. Those who merely glance over the beautiful series of fish-remains exhibited in the gallery at South Kensington are apt to carry away too sanguine an impression of the osteological information which is to be obtained from their study. It is a fact that, on some very essential points, fossil remains, however numerous and well preserved they may appear, still fail to afford the information which is most wanted. As an example we would allude

to the regrettable fact that the author has been obliged to abandon the use of a very important character in the definition of the higher groups, viz. the presence or absence of the mesocoracoid or "precoracoid" arch, the presence of which in the Isospondyli as understood by Cope had been duly emphasised in the diagnosis of this suborder at the end of the preceding volume. The Isospondyli are now made to include the Haplomi, an innovation with which the reviewer is unable to agree for the reason that the study of recent fishes proves their separation to be absolutely necessary. Even where the character of the "precoracoid process" is appealed to for the definition of families, error has crept in, at least in the case of the Gonorhynchidæ, which are stated to be devoid of it, and hence are unjustifiably regarded as "only slightly modified Scopelids." Other points in the identification of the elements of the pectoral arch seem in need of revision, as in the Thrissopater figured on plate vii., where the bone named "postclavicle" either represents the supraclavicle or overlies the latter and the clavicle, in which latter case it does not, as I believe, answer to the definition of the Elopidæ, and in the restoration of *Eurypholis boissieri*, p. 206, where the basalia of the pectoral fin are represented as attached to a bone termed "postclavicle." In the definition of the Apodes, "pectoral fin with more than five basalia" is true of Anguilla, but does not apply to Conger and other genera.

It is clearly often impossible to assign extinct fish-remains to their systematic position with that rigid precision which may be attempted in the case of living forms. Dr. Woodward, as he tells us in the introduction, has therefore deemed it advisable to adopt a broad conception of families and genera more in accordance with that of Dr. Günther than with that of later writers. But his classification, on the whole, is greatly ahead of that followed in Zittel's manual and in the text-books published in this country. He has amply availed himself of the reforms introduced by Cope and by Sagemehl. The arrangement of the great group of Acanthopterygians is still the most unsatisfactory, the definition of its subdivisions being of a very provisional nature and lacking in precision; groups like the Beryciformes, Chætodontiformes and Blenniiformes are certainly quite artificial, and the new sense in which these terms are used must be regarded as a retrograde step. Some explanation might have been given by the author of the reasons that have induced him to place the Blochiidæ among the Blenniiformes rather than among the Scombriformes.

The fossil forms dealt with under the Isospondyli offer a highly interesting and suggestive gradation from the later Ganoids to the earlier Acanthopterygians, such as the Berycidæ, so abundant in Cretaceous formations, but we are unfortunately still without a clue to the derivation of the eels proper, or Apodes, degenerate fishes which are traced back to the Chalk. Among these, Urenchelys, from the Chalk of Mount Lebanon, is shown to differ from existing genera of the same family in having a small caudal fin supported by expanded hypurals, thus showing the "diphycercal" condition which prevails at the present time to have been derived from a "homocercal." The Percesocine genus Cobitopsis settles once for all the vexed question of the systematic position of our sand-launce, Ammodytes, as it has retained the abdominal pelvic fins which have entirely disappeared in the existing genus; Ammodytes must hence be removed from the Ophidiid Anacanthines and placed near the Scombresocids or gar-pike and allies.

The publication of the "British Museum Catalogue of Fossil Fishes" marks a great advance in ichthyology, and we heartily congratulate Dr. Smith Woodward on its completion. It is announced in the preface that the author proposes to prepare, in the course of the present year, a supplement giving a list of additional important genera discovered and published since the earlier volumes were issued, the first dating as far back as 1889; also a stratigraphical table showing the appearance in time of families and genera of fossil fishes, together with a general index to the four volumes.

A last word as to the illustrations. The plates, as well as the outline figures in the text, are excellent, both from the point of view of artistic finish and scientific accuracy, and do the greatest credit to the artist, Miss G. M. Woodward. The intercalation of a collotype plate (xvii.) is, however, to be regretted, as not in keeping with the style of the other illustrations and quite superfluous, the figures having already appeared elsewhere, although no allusion to this is made in the accompanying explanation.

G. A. B.

OUR BOOK SHELF.

Tales of a Dying Race. By Alfred A. Grace. Pp. x+250. (London: Chatto and Windus, 1901.)

THE title of this little book is somewhat misleading. Out of eight-and-twenty tales, only four are, properly speaking, Maori tales. The rest are stories of the contact between the Maories and the white settlers, traders and missionaries. Even the four Maori tales are retold in *pakeha* fashion, until there is little of the Maori left in them beyond the skeleton. The majority have already appeared in antipodean periodicals. They are all charmingly told, and, illustrating as they do many sides of the Maori character and the romance of earlier days of the colony, they form a worthy tribute to the noblest of savages, and cannot fail to rouse vivid feelings of regret that the race is doomed to extinction. Mr. Grace writes of the people and their surroundings with keen sympathy, the full secret of which is not disclosed until the last story, in which he relates an adventure of his early life as a missionary's son, when his mother and her children were rescued from an impending and horrible death by the unflinching courage and fidelity of a native chief. He has done well to preserve the narrative, as well as the other contents of this entertaining book, in a permanent form; but he himself would hardly claim scientific value for the collection.

Lehrbuch der Differentialgleichungen. Von Dr. H. Liebmann. Pp. vi + 226. (Leipzig: Veit and Co., 1901.)

THIS interesting and well-written book shows that the ideas of Sophus Lie are at last bearing fruit, even in elementary text-books. There are three chapters dealing respectively with ordinary differential equations of the first order, with similar equations of higher order and systems of such equations, and with partial differential equations of the first order with two independent variables. Besides this, there is an introductory chapter dealing mainly with existence-theorems, and a concluding one on partial differential equations of the second order.

The examples are numerous, and admit of geometrical interpretation; many of them illustrate the theory of tangential transformations, which, happily, receives a good deal of attention. The articles on existence-theorems appear to be sound, so far as they go, and are unusually readable. Altogether, Dr. Liebmann's book may be recommended as a useful introduction to the modern treatment of the vast subject with which he deals. M.

The Theory of Equations: with an Introduction to the Theory of Binary Algebraic Forms. By W. S. Burnside, M.A., D.Sc., and A. W. Panton, M.A., D.Sc. Fourth edition. 2 vols. Pp. xiv + 286 and xii + 292. (Dublin: Hodges, Figgis and Co., Ltd.; London: Longmans, Green and Co., 1899, 1901.)

IN this new edition of a well-known and popular treatise the principal change is the addition of a chapter on the theory of substitutions and groups. Following the methods of Serret, Jordan and Netto, the authors give just so much of the elementary theory of substitution-groups as to enable them to prove the fundamental property of the Galoisian resolvent of an equation, and to demonstrate that the general equation of any degree higher than the fourth cannot be solved by an algebraic formula. It is strange that no reference is given to the work of Kronecker and others on equations which do admit of algebraic solution.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Note on Electric Charging and Discharging at a Distance.

A NUMBER of experiments, which I began in 1888, continued in 1894 and again in 1896, have been waiting for publication until the completion of certain others that I have been hoping to find time to carry out. As, however, the results are somewhat akin to those on the discharge of insulated bodies that are of great interest at the present time, it may be worth while not longer to delay publishing a preliminary note on a few of them.

The interest of the experiments lies partly in the fact that I was not merely able to *discharge* an electroscope by means of various bodies, hot and cold, placed within distances from it varying between 1 cm. and 300 cm., but that I was also able to *charge* the electroscope by the same means. The special interest, however, arises from *cold* bodies, viz. cotton wool dipped in ether, methylated spirit, or dilute sulphuric acid, being different, so far as I am aware, from any that have hitherto been employed for discharging or charging an electroscope at a distance.

A gold-leaf electroscope was employed, its outer case properly screened with strips of tinfoil, and the knob replaced with a metal pot to increase its capacity. A charge sufficient to make the leaves diverge by rather more than a right angle was generally given, so as to render the collapse easy to see. In every case the sign of the charge was tested before it was noted.

I.—*Discharging an Electroscope at Short Distances by means of a Candle Flame.*—With an insulated candle flame at 15 cm. distance, the leaves collapsed in forty seconds, whether they were charged positively or negatively. At 40 cm. between the two, the positive charge leaked away more slowly than the negative. With 42 cm. distance, the leakage was very slow for both, and at 48 cm. there was none.

When the candle was earthed, by having a wire sticking into the wick, the discharge was quicker than when it was insulated, but not if the wire dipped into the melted wax. The flame of a match had no less power, and an electric arc no more power, than an uninsulated candle flame placed at the same distance.

II.—*Discharging an Electroscope at Long Distances by means of an Insulated Candle.*—The candle and the electroscope were next placed 150 cm. apart and a *negative* charge given to the electroscope. Result—no leakage. A glass rod was then rubbed, brought up to the candle on the side *remote* from the electroscope, and then withdrawn. When this had been done several times, the leaves began to collapse, and collapsed in jerks, each time the rod was excited, brought near the candle and withdrawn. The collapse appeared to take place at the withdrawal of the rod. The same experiment was performed with distances varying up to 200 cm. between the candle and electroscope, and the numbers of withdrawals and re-excitations of the glass rod that were needed before the leaves began to collapse were noted. It varied from 1, with a distance of 125 cm. between candle and electroscope, to 14, with a distance of 203 cm. Thus the number of excitations increased very rapidly with the distance. The same results were obtained by charging the electroscope positively and bringing rubbed sealing-wax up to the candle. The further the distance of the two apart, the longer was it before the leaves began to collapse and the slower was the collapse when it began.

III.—*Charging an Electroscope at Long Distances by means of an Insulated Candle.*—All the experiments in II. were repeated, but the electroscope and the candle were now charged with the *same* sign. The number of withdrawals before the leaves began to move was much the same as before, but now the leaves diverged more widely, whether both electroscope and candle were charged positively or negatively. The electroscope was then left uncharged, and the charge rod was brought up to the candle as before. The leaves then diverged, and were found to have a charge of the same sign as that of the rod. Thus a charged electroscope placed at a distance up to 200 cm. from an insulated candle can be discharged by repeatedly bringing a charge of the *opposite* sign near the candle, on the side remote from the electroscope, and, similarly, an uncharged electroscope can be charged with a candle and rod placed at distances up to 200 cm. from the electroscope.

IV.—*The same Experiments with an Earthed Candle Flame.*—None of the results in III. are obtained if the candle is earthed.

V.—*Discharging an Electroscope by means of a Red Hot Platinum Wire.*—I., II., III. and IV. were repeated with the candle replaced by a platinum wire kept red hot by a current from two Grove's cells, which were placed on a cake of sealing-wax standing on four cubes of paraffin wax when the cells were required to be insulated. The results were practically the same as with the candle flame, except that the platinum wire, when earthed, discharged a negatively charged electroscope, but not one positively charged. Also when it was insulated, it discharged the electroscope at as great a distance, in one case, as 300 cm. from it.

Since writing the preceding, I find that some experiments on discharging, and discharging by means of *hot* bodies placed at *short* distances from the electroscope, were described by Prof. Worthington at the meeting of the British Association in 1889.

VI.—*To Restore to Platinum Wire the Power to Discharge when it has lost it by being kept White Hot for many hours.*—Prof. Schuster first observed, I believe, that glowing platinum wire ceased to discharge electrified bodies near it after it had been kept white hot for some time. He attributed its discharging power to occluded gases and the loss to these having all been expelled. To see if the power could be restored to the wire by placing any substance on it, I first put a drop of oil on some wire that had lost its power, but with no effect. A grain of sugar was equally ineffectual, &c., but either salt or common washing soda was, I found, instantly efficacious. It seems possible, therefore, that it is some trace of a salt of sodium or other metal on an ordinary platinum wire that either enables, or assists, the hot wire to discharge, and that the white heat chemically cleans this off. I intend, however, to make further experiments on this point.

VII.—*Charging and Discharging an Electroscope by means of Cotton Wool dipped in Ether, Methylated Spirit, or Dilute Sulphuric Acid—the whole Insulated.*—II., III. and IV. were next tried, when the candle flame was replaced with an insulated saucer of cotton wool, saturated in turns with ether, methylated spirit and dilute sulphuric acid placed at a distance from the electroscope. Each was found to act just as well as the candle flame and in the same way. None would act when earthed, and carbon dust—dry—was quite ineffectual in both cases.

Many other experiments were tried, but the preceding are sufficient to show the nature of the phenomena observed.

HERTHA AYRTON.

The Origin of the Scale of Fahrenheit's Thermometer.

YOUR issue of February 13 contains, on p. 348, a note on the above subject, in which it is stated that Fahrenheit based his scale upon a scale previously adopted by Newton, Newton's scale having its zero at freezing point and the temperature of the human body marked as 12 degrees. Fahrenheit (says Sir Samuel Wilks) found Newton's divisions too large. He therefore divided them by two. Next he altered his zero to the temperature produced by a mixture of ice and salt. Later on he again divided each degree into four parts, giving the scale which is now in use. This explanation is substantially that which is given in the "Encyclopædia Britannica."

It is evident that the origin of the Fahrenheit scale is a matter of some speculation. A recent work, the "Evolution of the Thermometer," by Mr. H. C. Bolton (reviewed in NATURE of May 9, 1901), states that Fahrenheit's selection of a scale was unfortunate, and did not appear to have been based on anything.

It seems very unlikely that Fahrenheit, who was an accomplished man of science and experimenter, and whose thermometers were acknowledged to be a great advance on others existing at the time, should have based his scale on nothing at all.

An examination of the main features of Fahrenheit's work upon thermometers gives, I think, the key to the origin of the scale, and shows that he based it upon a very sound and scientific foundation. In discussing this question, one must have a regard for the state of the knowledge of kindred matters at the beginning of the eighteenth century, and consider how the problem would be likely to present itself to Fahrenheit.

Reference is made in the note to a paper in the *Philosophical Transactions* for 1701, supposed to have been written by Newton. In this paper, which is written in Latin, is described a scale of degrees of temperature (Scala graduum Caloris) from the freezing point of water to the melting point of gold, but it does not appear that this scale was intended to be actually applied to a thermometer. It seems only to be intended as a convenient scale of reference for comparing temperatures covering a very wide range. The zero or starting point is the freezing point of water. The external temperature of the human body is taken as the second point from which the scale is derived. The range of temperature between these two points is divided into twelve parts. The freezing point is, therefore, called 0, and the body temperature 12. The scale is continued upwards, and it was found that the temperature of water boiling violently corresponded to 34 degrees. Many other degrees are noted as indicating the melting points of metals, &c.

The paper continues with a description of a thermometer, the liquid element of which is linseed oil. The actual scale of the thermometer, however, was not that described above, but was determined as follows:—

The thermometer was placed in melting snow. The space filled by the oil in the bulb and the stem together was taken as occupying 10,000 parts. The same oil, when expanded by the heat of the human body, occupied a space of 10,256 parts, and by the heat of boiling water 10,725 parts. Thus, on this thermometer, if the freezing point was marked 0, body temperature was 256 and boiling water 725. It was by means of this thermometer that the temperatures were obtained from which the "Scala graduum Caloris" was computed.

Fahrenheit is credited with having been the first to use mercury in the thermometer. He also discovered how to produce a temperature much below the freezing point of water by mixing "ice, water and sal-ammoniac or salt."

In a paper (also in Latin) which he contributed to the *Philosophical Transactions* of 1724, on the subject of "Experiments concerning the Freezing of Water," he described his thermometer, but did not explain his reasons for adopting the particular scale. It may be safely assumed that he was acquainted with the paper published in 1701 referred to above.

Having then decided upon the use of mercury in his thermometer in place of the oil previously used, the problem upon what basis his scale should be constructed would next arise. What could be more natural than to base it upon the expansion of mercury itself? The idea of making his degree or unit that difference of temperature by which the liquid expands by one *ten-thousandth part of its volume* would naturally occur to him, for it had already been done in the case of the oil thermometer. That this is the basis of the Fahrenheit scale I think is proved by the fact that for each degree of the Fahrenheit scale mercury *does* expand by one ten-thousandth part of its volume.

Having, therefore, determined upon the size of his divisions or degrees, the next thing was to fix on a zero or starting point. What, again, could be more natural than to start with the greatest degree of cold which he knew how to produce, namely, the temperature of the ice and salt mixture? Having settled upon this, everything else follows, and we have the Fahrenheit scale as we know it to-day. The thermometer registers for freezing point 32°, blood heat 98½°, and boiling point 212°. In his own description of his thermometer, he states that the temperature of the body is 96°, but this slight error was probably due to the thermometer not being properly heated by that part of the body to which it was applied, and in any case does not affect this explanation, which, I think, suggests that the Fahrenheit scale is based upon scientific principles, and is not, as is often supposed, a scale without rhyme or reason.

GILBERT S. RAM.

The Inheritance of Mental Characters.

I QUITE agree with Prof. Cockerell that further discussion of this subject had better be postponed, if, indeed, it be not wholly unprofitable. But I may, perhaps, be permitted to make three remarks:—

(1) The coefficient of correlation is a measure of the degree of resemblance between brothers. We are told it may be due to "soul," heredity or environment. "Soul," I take it, can only contribute to likeness between brothers, if they have like "souls." If so, I suppose the likeness of "soul" is due to inheritance of "soul," and I do not see how this is going to be distinguished from other forms of heredity. I am not unaware of Dr. Wallace's views on spirit hierarchies. I considered them in my "Grammar of Science," and still hold them thoroughly illogical and unscientific.

(2) What I asked Prof. Cockerell to do was to explain why the intensity in inheritance of mental and physical qualities came out the *same*. He may have views why they ought to be different, but it remains for him to explain why soul + heredity + environment in one case = heredity + environment in the other.

(3) I believe the mental characters in man are far more persistent than Prof. Cockerell credits them with being. The relations between head-measurements and intelligence are almost identical whether we deduce them from young children or undergraduates, and there is no apparent change of correlation when we compare brothers at close and at more distant ages. It is perfectly possible to determine from our data the proportions of children at each age with given mental characters. Prof. Cockerell belongs to those critics who live in the region of "may-be." If he will collect observations on some 5000 to 6000 children as we have done, he may still come down from the region of "may-be" and be able to place fact against fact.

University College, London. KARL PEARSON.

The Colours of Wings in Butterflies.

YOUR correspondent in India, W. G. B. (NATURE, February 13, p. 344), has been examining a butterfly in some ways like the *Morpho Cypris* of South America, the difference being that the latter has the upper side brilliant and the lower side brown.

The Morpho can be placed so that the two wings on one side of the body are metallic blue, while the other two are black; with a slight turn the two sides reverse colours. This seems to be like the case of the Purple Emperor, in which all edges of the scales facing one way are blue, and other edges are brown. A ploughed field with furrows running east and west might after snow and sunshine appear white from the north and black from the south. In London it is easy to see the Morpho; instead of the furrows it is possible to take for illustration a common form of advertisement.

The Morpho, like the Indian specimen, presents shades of ultramarine, peacock-blue, and sea-green; also in transmitted light the scales are golden. In most cases of coloured surfaces we are not yet able to point out the action on the light waves. Prof. Tyndall showed how small particles in air or water might reflect blue waves and allow the larger red waves to curl round them and go forward; but this does not apply to a surface which reflects the larger waves. It can only be said that coloured surfaces are such as have the power at a minute depth of selecting some waves for reflection; in the case of gold leaf or some butterflies' wings, the remainder of the light may be seen, transmitted almost without any loss by absorption, as the thickness traversed is so

minute. It is familiar knowledge that the intensity and the polarisation of reflected and transmitted lights vary with the incidence; and it seems likely that in the Morpho the changing tints of blue may arise through a varying partition of the reflected and transmitted colours. While, then, diffraction does not usually affect the appearance of the wings, it is, however, interesting to a student in optics to use the scales for experiment. Let a few wings, light-coloured for preference, have the scales scraped off on to a piece of glass, and let these be covered with glass as in a lantern slide; when they are placed in strong sunlight, there is the appearance of so many minute sparkling diamonds.

Since I wrote before, I have felt that in humming-birds also the colour is seldom due to diffraction. In one which I have before me, the head is red or black, the breast is golden or olive-green; the details of the feathers have two colours, one on each edge. They are strong mixed colours, not like spectrum colours of any order. In the Gould collection at South Kensington I was, however, able to find two birds—*Rhodopis vesper* and *Calypte annae*—in which the pigment colours were so subdued that diffraction lights were able to have some influence in the mixed effect. W. B. CROFT.

Winchester College, February 17.

Birds attacking Butterflies and Moths.

IN connection with the controversy on the above subject, I am permitted to add the testimony of an old friend of mine, Mr. H. S. Wise, of Ford, Drewsteignton, South Devon, an extremely keen and accurate observer, with wide experience both of British and Indian fauna. In letters to me dated February 9 and 12, 1902, he says:—"I have seen birds attack butterflies both in England and in India," and gives the following notes:—"On summer evenings, magpies hunt a grass field and catch immense numbers of moths, beetles and, I believe, butterflies. . . Last summer I shot a magpie, one of a family that was carefully working a large grass field; his beak was full of recently-caught Swift Moths (*Hepialus lupulinus*)." Later he says, "I have seen the common spotted flycatcher pursue a butterfly and miss it, giving up the pursuit; this was of course on the wing." Further, "titmice eat quantities of small moths, which they catch when at rest." Speaking of the large Yellow Underwing (*Tryphoena pronuba*), Mr. Wise tells me, "several small birds eat this moth, sparrows among the number; it is a strong moth, and the bird generally beats it on the ground to kill it before eating it. This insect is fond of lying on the ground among leaves, &c., and birds will hunt it out and catch it." Among other enemies of British Lepidoptera, Mr. Wise notes that "bats feed largely on the night-flying moths; *Tryphoena ianthina* is one I have seen them catch." My friend also refers to a note by G. C. Dudgeon, in the Journal of the Bombay Natural History Society for March 20, 1895, on the King Crow (*Dicrurus longicaudatus*) catching a butterfly (*Teinopatpus imperialis*, ♂), and adds, "In the case of a jungle-fire in an Indian forest, birds at once come and catch the numerous insects which fly up for safety, the above-mentioned King Crow being always to the fore." In India also lizards are formidable enemies to Lepidoptera. Mr. Wise says, "in Bombay there is hardly a lamp-post which has not got a gecko on it; these feed on the moths which are attracted to the light."

Mr. H. S. Wise, I am glad to say, promises to devote especial attention this summer to the question of birds attacking Lepidoptera, and to note, whenever possible, the name of the bird and the victim. If naturalists would more generally devote time to such work, we should soon accumulate sufficient direct evidence of the severity of the struggle for existence to place the matter beyond the possibility of dispute.

I regret to find that in my previous letter (p. 299) I unintentionally added a word to Mr. Latter's phrase, which should read "relinquished its hold in consequence of a luckily-aimed stick"—not "*only* relinquished," &c. The difference is not, however, essential, as the stick is stated to have been a cause of the bird's action. LILIAN J. VELEY.

20 Bradmore Road, Oxford, February 15.

ONE morning in 1901 (actual date not recorded) I found a Humming-bird Hawk (*Macroglossa stellatarum*) on a window in my house. I opened the window and tossed it out, thinking it would fly away, but it fell to the ground, where it remained quivering its wings within six feet of me.

A House Sparrow flew down from a Deodar, and with four dexterous pecks separated the wings from the thorax; it then pecked the middle of the thorax, splitting it, and with one or two more pecks separated the abdomen from the thorax. Taking the abdomen in its beak, the sparrow flew back to the tree from which it had come and, I presume, made a hearty breakfast.

The sparrow attacked the hawk in such a business-like way that it was obviously no new proceeding on its part.

There is always a martin's nest in my porch, and it is not uncommon to find wings and thorax of Agrotis, &c. on the seats or floor. JOHN HARTLEY DURRANT.

Merton Hall, Thetford.

The Severn Bore.

SINCE writing to you on February 12, I have had the opportunity of observing the bore of this morning, a tide which corresponds with that of February 12, 1899, which was remarkable. But to-day's "head" was a very poor one indeed, for no reason that I can find out; no wind and no fresh water in the river of any consequence. The only measure that I could make was of the wave at the shore, which at one point, and one point only, rose to 2¼ feet, whilst in midstream there was but little visible.

A distance of 520 yards having been measured out, and the time of passage having been taken by watches, I found that the speed was a fraction under 15 miles per hour.

The period occupied by the passage of the "head" from Newnham ferry was one hour; the mileage taken from the Ordnance map is a little over ten miles; average speed is, therefore, ten miles per hour.

This average cannot be far from correct, for I measured at Newnham, where the river is broad, and with wide sand-banks, which spread out on either side, up to Framilode, a distance of 5·2 river-miles, and here the banks begin to approach one another, and at five miles further up the stream is only 250 feet wide. E. W. PREVOST.

Newnham, February 24.

Beautiful Birds.

IN reviewing my child's book, "Beautiful Birds," F. E. B., writing in your columns, says, "Why should he select the 'beautiful birds' only, and, by implication, condone the massacre of birds that have not that advantage?" The question is a misstatement of fact, which I hope you will allow me to show, though I can only do so by quoting myself. On the last page—which I daresay F. E. B. did not get to—there is this: "'Mother, promise not to wear *any* feathers except the beautiful ostrich feathers that you look so *lovely* in?' As soon as she has promised, then all the beautiful birds in the world (and that means all the birds, for all birds are beautiful) will be saved," &c. (The italics are mine). This is the final promise and the goal to which I have been leading. May I ask F. E. B. whether, if he wished to arouse a child's interest and sympathies in any subject, he would choose the more or the less salient material to do it with?

19 Clarence Square, Cheltenham, Feb. 9. EDMUND SELOUS.

I ADMIT that I did not observe the phrase which Mr. Selous quotes from his book. But supposing that he can quote half-a-dozen such, I cannot allow that my observations to which he takes exception contain any injustice to him or real misstatement of fact. I would commend to Mr. Selous Dr. Samuel Johnson's sound remark concerning a quite analogous statement. An orchard, observed the Doctor, would be properly described as barren of fruit, even if subsequent research discovered a dozen apples and pears upon two or three trees. Now Mr. Selous' book is called "Beautiful Birds." It is not called "Birds." It is clear, too, what Mr. Selous means by "beautiful." His plates and the greater part of his descriptions deal with the Paradiseidæ, Humming Birds, and other birds which everyone calls beautiful. I do not find chapter after chapter relating to partridges, quails, sparrows, and other "plain" birds.

F. E. B.

King Og's Bed.

A HEBRAIST once told me that he thought that Og's iron bed, mentioned in Deuteronomy iii., 11, was a sarcophagus of basalt. The Hebrew word is "barzel," which is evidently the same as the Ethiopic "basal," iron, which Stormonth's dictionary gives as the derivation of "basalt." O. FISHER.

Harlton, Cambridge, February 20.

THE ROYAL SOCIETY AND THE PROPOSED ACADEMY.

A COPY of the following petition referring to the proposed British Academy has been sent to us for publication:—

To the KING'S MOST EXCELLENT MAJESTY IN COUNCIL

The Humble Petition of

AVEBURY, F.R.S., P.C., Past President, British Association
C. ROBERT SPENCER, P.C., M.P.
WELBY, G.C.B., Past Permanent Secretary of the Treasury, Alderman L.C.C.
G. F. BRISTOL
ROWLAND BLENNERHASSETT, Bart., LL.D., President of the Queen's College, Cork; Senator of the Royal University of Ireland
WM. DUNN, Bart., M.P.
LOWTHIAN BELL, F.R.S.
JOHN KIRK, G.C.M.G., K.C.B., F.R.S.
W. B. RICHMOND, K.C.B., R A.
W. H. WHITE, K.C.B., F.R.S., Past Director of Naval Instruction
W. H. PREECE, K.C.B., F.R.S., Past Engineer-in-Chief G.P.O.
C. W. WILSON, R.E., K.C.B., F.R.S., Past Director-General Ordnance Survey
J. NORMAN LOCKYER, K.C.B, F.R.S., Director Solar Physics Observatory, South Kensington
R. GIFFEN, K.C.B., F.R.S., Past Controller-General of Commercial Labour and Statistical Department Board of Trade
SPENCER WALPOLE, K.C.B, Past Secretary of the Post Office
WM. TURNER, K.C.B., F.R.S., President of the General Medical Council; Past President of the British Association
HENRY CRAIK, K.C.B., Secretary Scotch Education Department
DONALD MACKENZIE WALLACE, K.C.I.E., K.C.V.O.
B. BAKER, K.C.M.G., F.R.S.
A. E. BATEMAN, K.C.M.G., Comptroller-General for Commerce, Labour and Statistics Board of Trade
ARCHIBALD GEIKIE, F.R.S., Past Director-General of Geological Survey; Past President of the British Association
WILLIAM CROOKES, F.R.S., Past President of the British Association
H. T. WOOD, Secretary of the Society of Arts
W. MARTIN CONWAY, Slade Professor of Fine Arts, Cambridge University; Past Chairman of the Society of Authors
JOSHUA G. FITCH, Past Chief Inspector of Training Colleges
LAUDER BRUNTON, F.R.S., Physician to St. Bartholomew's Hospital
OWEN ROBERTS, Clerk to Worshipful Company of Cloth-Workers
WEMYSS REID
C. HUBERT H. PARRY, Professor of Music, Oxford University
J. BENJAMIN STONE, M.P.
WALTER PARRATT, M.V.O., Master of the King's Musick
WALTER FOSTER, M.D., D.C.L., M.P.
JOSEPH LEIGH, M.P.
LEWIS MORRIS
R. R. HOLMES, C.V.O., Librarian to His Majesty at Windsor; Fellow and Member of Council of the Society of Antiquaries
E. ROBERT FESTING, F.R.S., Director Science Museum, South Kensington
E. W. BRABROOK, C.B., Chief Registrar of Friendly Societies; F.S.A., Past President Anthropological Institute
D. R. FEARON, C.B., Charity Commissioner
EDWARD DICEY, C.B.
A. SCHUSTER, F.R.S., Professor of Physics the Owens College, Manchester
R. MELDOLA, F.R.S., Professor of Chemistry Finsbury Technical College
HORACE T. BROWN, F.R.S.
JOHN I. THORNYCROFT, F.R.S.
T. G. BONNEY, F.R.S., Past President Geological Society
SIDNEY LEE
CECIL SMITH, Assistant Keeper Department of Greek and Roman Antiquities British Museum
GEORGE A. MACMILLAN, Hon. Sec. Hellenic Society
CHARLES VILLIERS STANFORD, Professor of Music Cambridge University
N. MACCOLL
T. BAYLEY, M.P.
A. SIEMENS
A. A. COMMON, F.R.S., Past President Royal Astronomical Society
EMANUEL GREEN, Vice-President Royal Archæological Institute
F. C. PENROSE, F.R.S., Past President Royal Institute of British Architects
E. ROBERTSON, K.C., M.P.
JOHN PERRY, F.R.S., Professor of Mathematics Royal College of Science
T. BAILEY SAUNDERS
A. CONAN DOYLE
T. CLIFFORD ALLBUTT, F.R.S., Regius Professor of Physic in the University of Cambridge
BENJAMIN KIDD
C. H. READ, Keeper of British Antiquities British Museum; Secretary Society of Antiquaries and Past President Anthropological Institute
G. HY. BOUGHTON, R.A.
S. ALEXANDER, Professor of Philosophy at the Owens College
ALFRED HOPKINSON, Principal of the Owens College
SIDNEY J. HICKSON, F.R.S., Professor of Zoology the Owens College
J. F. TOUT, Professor of History the Owens College
HORACE LAMB, F.R.S., Professor of Mathematics the Owens College
A. S. WILKINS, Professor of Latin and late of Comparative Philology the Owens College
W. BROMLEY-DAVENPORT, M.P.
FREDERICK WM. FISON, M.P.
H. S. KING, M.P.
THOS. P. WHITTAKER, M.P.
REGINALD LUCAS, M.P.
A. G. GREENHILL, F.R.S., Professor of Mathematics Artillery College, Woolwich
ISAMBARD OWEN, Deputy Chancellor of the University of Wales
ALFRED C. HADDON, F.R.S., President of the Anthropological Institute
W. J. M. HILL, F.R.S., Professor of Mathematics University College, London
HEREFORD B. GEORGE, Fellow of New College, Oxford
W. H. HADOW, Fellow of Worcester College, Oxford
W. A. SPOONER, Fellow of New College, Oxford
A. V. RICHARD, Fellow of New College, Oxford
OLIVER J. LODGE, F.R.S., Principal, University of Birmingham
J. H. POYNTING, F.R.S., Professor of Physics University of Birmingham
BENEDICT W. GINSBURG, LL.D. (Cantab.)
P. S. CRAIGIE, Hon. Sec. Royal Statistical Society
R. HENRY REW
G. GRIFFITH, Assistant General Secretary British Association
E. RAY LANKESTER, F.R.S., Director of the Natural History Departments British Museum
PERCY F. FRANKLAND, F.R.S., Professor of Chemistry University of Birmingham
JOHN G. MCKENDRICK, F.R.S., Professor of Physiology University of Glasgow
BERTRAM C. A. WINDLE, F.R.S., Professor of Anatomy and Dean of the Medical Faculty University of Birmingham
DAVID FERRIER, F.R.S., Professor of Neuro-Pathology King's College, London
O. HENRICI, F.R.S., Professor of Mathematics City and Guilds Central Technical Institute
W. GREENWELL, F.R.S., Canon of Durham
REGINALD L. POOLE, Lecturer in Diplomatic in the University of Oxford
P. L. SCLATER, F.R.S., Secretary Zoological Society
GEORGE BRODRICK, Warden of Merton College, Oxford
ALEX. CRUM BROWN, F.R.S., Professor of Chemistry University of Edinburgh
JAMES GEIKIE, F.R.S., Professor of Geology University of Edinburgh
E. A. SCHÄFER, F.R.S., Professor of Physiology University of Edinburgh

BEN. N. PEACH, F.R.S., H.M. Geological Survey
JOHN HORNE, F.R.S., Assistant Director of the Geological Survey for Scotland
C. LLOYD MORGAN, F.R.S., Professor of Biology and Geology in University College, Bristol
SYDNEY YOUNG, F.R.S., Professor of Chemistry in University College, Bristol
W. BOYD DAWKINS, F.R.S., Professor of Geology and Palæontology in the Victoria University, Manchester
R. T. GLAZEBROOK, F.R.S., Director National Physical Laboratory
H. B. TRISTRAM, F.R.S., Canon of Durham
H. KYNASTON, D.D. (Camb.), Canon of Durham and Professor of Greek in the University of Durham
L. C. MIALL, F.R.S., Professor of Biology Yorkshire College
ARTHUR SMITHELLS, F.R.S., Professor of Chemistry Yorkshire College
J. B. BRADBURY, F.R.S.E., M.D., Downing Professor of Medicine University of Cambridge
THOS. W. SHORE, F.G.S., Hon. Sec. London and Middlesex Archæological Society
W. E. AYRTON, F.R.S., Professor of Electrical Engineering City and Guilds Central Technical College
ASTON WEBB, A.R.A.
G. B. HOWES, F.R.S., Professor of Zoology Royal College of Science
WM. GARNETT, Secretary Technical Education Board L.C.C.
ADAM SEDGWICK, F.R.S., Reader of Animal Morphology University of Cambridge
W. ALDIS WRIGHT, Vice-Master Trinity College, Cambridge
THOMAS SHAW, K.C., M.P.
WILLIAM RAMSAY, F.R.S., Professor of Chemistry in University College, London
H. CHARLTON BASTIAN, F.R.S., Emeritus Professor of Medicine University College, London
F. A. CHANNING, M.P., Past Lecturer in Philosophy University College, Oxford
WM. ALLAN, M.P.
ISAAC BAYLEY BALFOUR, F.R.S., King's Botanist in Scotland
FRANCIS ELGAR, F.R.S., Past Director of H.M. Dockyards
N. BODINGTON, Litt.D., Principal, Yorkshire College
FRANK E. BEDDARD, F.R.S., Vice-Secretary Zoological Society

Sheweth

That Whereas His Majesty King Charles II., in order to prove that His Majesty did "look with favour upon all forms of Learning" and particularly "Philosophical Studies," and in order that such Learning and Studies should "shine conspicuously" among his People, did by Charters granted in the 14th, 15th and 21st years of His Reign found the Royal Society for the promotion of such Learning and Studies

And Whereas the progress of Learning and Philosophical Studies has been great, and scientific methods of inquiry have been applied to many new fields of knowledge since the time of His Majesty King Charles II.

And Whereas Your Petitioners are of opinion that it is desirable that all the Intellectual forces of the Realm should be so organised as to promote the greatest advancement of Scientific Studies within the Empire

And Whereas a large and influential group of representatives of Studies connected with History, Philosophy and Philology have lately presented a petition to Your Majesty praying to be embodied under Royal Charter as an Academy or like institution

And Whereas Your Petitioners are of opinion that such incorporation can be most efficiently provided for in some relationship to the Royal Society

We Your Petitioners humbly pray that Your Majesty may be graciously pleased to cause an Inquiry to be made with a view of instituting a general and formal organisation of all the Studies depending upon Scientific Method now carried on similar to that inaugurated for the Philosophical Studies of the 17th century by the Charters of His Majesty King Charles II.

And Your Petitioners will ever pray,

POSITION AND PROMISE OF WIRELESS TELEGRAPHY.

THE meeting of Marconi's Wireless Telegraphy Company held last week was of more interest than such meetings usually are, as Mr. Marconi made use of the opportunity by replying in a long speech to the many adverse criticisms which had been passed on his work. No new development has ever been brought about without having to encounter a certain amount of opposition; wireless telegraphy is no exception to the general rule, and the criticism which it has had to meet has been accentuated on account of the magnitude of the interests vested in cable enterprise. But wireless telegraphy has also enjoyed more than its share of popular enthusiasm, and it is perhaps partly on account of the unreasoning nature of this enthusiasm that technical writers have thought it desirable to sound a warning note. It is doubtless unnecessary to sell out cable shares immediately because the signal "S" has been successfully transmitted across the Atlantic, but it is equally unnecessary to assume that the result is not genuine before the details of the experiments have been published. With reference to these recent experiments, and the suggestion put forward by some of the technical papers that Mr. Marconi was deceived by atmospheric disturbances, he appeals, we think with justice, to his long experience in the matter as sufficient guarantee of the genuineness of the result, and points out that in his first successful experiment over 200 miles it was the same signal that was received.

The question has often been asked, Why is it that, if a distance of 2000 miles can be bridged, the system is not in actual commercial operation over shorter distances?

To this Mr. Marconi replies that the Post Office monopoly prevents its adoption round the coasts of this island, but that it is in continuous and perfectly satisfactory work in connection with more than seventy ships and twenty-five land stations, as readers of NATURE are aware from paragraphs which have appeared from time to time in our Notes columns.

The greatest interest, however, centres around the questions of the speed and the secrecy of signalling. Mr. Marconi states that with his latest apparatus a speed of twenty-two words a minute is obtainable. For short distances much higher cable speeds are possible, but in Transatlantic work the speed of signalling under the best conditions is only about forty words per minute, so that in this respect wireless telegraphy can certainly become a serious competitor. Distance, it is stated, has no effect on the rapidity of signalling by ætheric waves, a result which was, of course, to be anticipated on theoretical grounds.

As to secrecy, Mr. Marconi asserts that the development of his syntonic system has been carried so far that no interference troubles need be feared, and quotes an interesting example in support of this contention. The permanent station at the Lizard is at present able to work with ships without suffering any interference from the working of the big-power station at Poldhu, only seven miles distant, from which the signals were transmitted to Newfoundland. The solution of the problem of tuning has always been seen to be of fundamental importance to wireless telegraphy, and if Mr. Marconi has successfully achieved this result, it is a development greater and more far-reaching than even the Transatlantic signalling. That he is himself confident of having done so may be inferred from the challenge which he issued to Sir W. Preece and Prof. Lodge to intercept and read any of his messages, for which purpose he offers to put any of his adjacent stations at their disposal.

At the present day, when the general public takes

so much interest in scientific progress, any new development becomes so soon the centre of numberless contradictory and inaccurate reports that it is often difficult to get at the truth of the matter. Mr. Marconi's authoritative statement last Thursday is therefore very welcome. Even those most sceptical of the ultimate value of the discovery cannot but admire the energy and perseverance which Mr. Marconi has shown throughout. Whilst others have been pointing out its impracticability, he has been steadily making it practicable, and, considering the splendid results which he has already achieved, one cannot help sharing his confidence in his ultimately attaining complete success. M. S.

PROF. I. V. MUSHKETOFF.

WE regret to see the announcement of the death of Prof. Ivan Vasilievich Mushketoff, the president of the physical geography section of the Russian Geographical Society, at the age of only fifty-two.

Prof. Mushketoff was from the Don region, where he was born in 1850, and received his early education at the Novocherkask lyceum. In 1867 he entered the St. Petersburg University, joining the philological faculty, but soon went over to the Mining Institute.

Already while a student he published his first original research on the Volhynite, and in 1872 he began his continuous, almost uninterrupted explorations of Russia, first in the Urals, where he discovered a gold-bearing formation of arsenicated minerals—pharmacosiderite, arseniosiderite, &c.—and then on the Don. Next year, 1873, he was in Turkestan, where he remained for six years, making extensive journeys. He embodied the results of his explorations in a great number of geological and geographical papers, as also in a remarkable work, "Turkestan," vol. i. (1886), which was described in these pages, and, with Prof. Romanovsky, in a geological map of Turkestan.

In 1881, Mushketoff began the exploration of the Caucasus, and especially of the Astrakhan, the Kalmyk and the Kirghiz steppes, and later on of the Transcaspian region, of which he published an excellent geological description, with a map, in 1892.

A second journey to Turkestan, in order to explore the earthquake at Vyernyi, brought Mushketoff to the study of earthquakes in Russia, for which purpose numerous regular observations and a catalogue of earthquakes (by Orloff) were published by him in the periodicals of the Geographical Society. Later on he became interested in glaciers, and organised for the International Commission on Glaciers the first regular observations in Russia upon the oscillations of the glaciers of the Caucasus. All these researches enabled him to publish the first volume of an excellent course of physical geography (1891) and a short course of petrography (1895). In 1882 he was nominated head geologist of the Geological Committee, and took, in this capacity, a lively part in the geological survey of Russia. From 1885 he was president of the physical geography section of the Russian Geographical Society, and in this capacity he took, with P. P. Semenoff, the liveliest part in the organisation of all the expeditions of the Society, as well as in its publications, of which the "Annuary" is perhaps the most remarkable for the fulness of information about all geographical, geological, geo-botanical, geo-zoological and anthropological work done in Russia.

In Mushketoff, both Russia and science have lost one of their best physical geographers. He was at the same time an excellent man, and the obituary notices published in the Russian papers represent him as a most sympathetic friend of the Russian youth. P. K.

NOTES.

M. C. ANDRÉ has been elected a correspondant of the Paris Academy of Sciences, in the Section of Astronomy.

THE council of the Zoological Society has resolved to bestow the gold medal of the Society upon Sir Harry Johnston, in consideration of his very great services to zoological science, and in commemoration of his discovery of the Okapi, and the silver medal of the Society upon Mr. E. W. Harper, of Calcutta, in acknowledgment of his numerous contributions of rare Indian birds to the Society's collection. These medals will be presented at the general meeting of the Society on June 19.

IN accordance with the usual custom, the French Physical Society announces that two meetings for the exhibition of experiments described before the Society during the year will be arranged for on Friday and Saturday, April 4 and 5. On the first evening members only will be admitted; the second will be open to visitors. The rooms of the Society (44 Rue de Rennes, Paris) will be open during the whole of the Saturday for those desirous of studying the experiments more at their leisure than is possible in a crowded meeting.

THE Belgian Royal Academy makes the following announcements as to awards of prizes on scientific subjects for 1901:—For the first question, as to the part played physiologically by albuminoid substances in the nutrition of animals or vegetables, no award has been made. For the second question, relating to the organisation and development of a Phoronis, one essay has been submitted which has been adjudged worthy of honourable mention. On the subject of the effect of external influences on karyokinesis and cell-division in plants, an essay has been submitted by Mdlle. Maria Maltaux, of Laeken, to whom a silver medal has been awarded. The Charles Lemaire prize has been awarded to M. Paul Christophe, engineer of the Belgian "Ponts et Chaussées."

MR. CARNEGIE'S gift of ten million dollars, in 5 per cent. bonds of the United States Steel Corporation, for the promotion of scientific research, has already been announced in these columns, and an outline has been given of the Carnegie Institution to be founded for this purpose (pp. 278, 302). A meeting of the trustees of the institution was held at the end of January, when Mr. Carnegie described briefly the object he had in view in making the gift, and gave emphasis to his repeated desire that the income of the fund should be largely devoted to extending human knowledge by original investigation and research. The methods by which knowledge is to be advanced are left to the free action of the trustees, who will await the carefully matured suggestions of the executive committee. "Nothing," says *Science*, "has been done in founding the new institution to further or to hinder the establishment of a national university which has been so many times proposed to Congress. Nothing is projected which will in any way interfere with the purpose of the George Washington Memorial Association to secure the funds requisite for the erection of a memorial building. Nor has there been any step taken which will prevent the Washington Memorial Institution, initiated early in the last summer, from developing plans for the introduction of students to the various scientific bureaus of Washington. The Carnegie Institution is simply a new force for the promotion of science, ready to cooperate with other institutions which are now or may be established in Washington or elsewhere."

THE Russian Geographical Society has awarded this year its Constantine medal to the geologist, K. I. Bogdanovitch, who has spent several years in the exploration of Central Asia and

has contributed one large volume to the beautiful series of quarto volumes edited by the Society and devoted to this part of Asia. The Semenoff medal has been awarded to Prof. Eduard Suess for his new classical work, "Das Antlitz der Erde," and the Prjevalsky medal to the zoologist, Prof. Zarudnyi, the author of several most valuable works on the birds and also the geography of the Transcaspian region, and the author of a work, "Journey to East Persia," just published by the Society. The great gold medal of the Section of Statistics has been awarded to N. V. Slyunin, for his researches into the economical conditions of the inhabitants of the Okhotsk and Kamchatka coasts. Three small gold medals have been awarded to Messrs. N. P. Petrovsky, D. K. Zelenin and M. N. Kositch for ethnographical works published in the excellent ethnographical periodical of the Society, *Zhivaya Starina* (*Living Antiquities*). Prof. Gordyaghin, of Kazan, has been awarded the Prjevalsky silver medal for his botanical work in East Russia, and the Semenoff silver medal has been awarded to A. K. Bulatovich for his journey to Lake Rudolph. A number of small silver medals have also been awarded, chiefly for meteorological work in connection with the Society's meteorological committee, or for expeditions.

THE Elizabeth Thompson Science Fund, "for the advancement and prosecution of scientific research in its broadest sense," now amounts to 5200*l.*, and grants will be made in November from the income derived from this sum. This endowment is not for the benefit of any one department of science, but preference will be given to those investigations which cannot otherwise be provided for, which have for their object the advancement of human knowledge or the benefit of mankind in general, rather than to researches directed to the solution of questions of merely local importance. Applications for assistance from this fund, in order to receive consideration, must be accompanied by full information, especially in regard to the precise amount required; exact nature of the investigation proposed; conditions under which the research is to be prosecuted; and manner in which the grant asked for is to be expended. All applications should reach the secretary of the Board of Trustees, Dr. C. S. Minot, Harvard Medical School, Boston, Mass., U.S.A., before April 1. During the past twelve months, the following grants have been made:—30*l.* to Prof. E. W. Scripture, New Haven, Conn., for work in experimental phonetics; 60*l.* to Prof. W. Valentiner, Heidelberg, for observations on variable stars; 10*l.* to Mr. A. M. Reese, Baltimore, Md., for investigation of the embryology of the alligator; 25*l.* to Dr. F. T. Lewis, Cambridge, Mass., for investigation of the development of the vena cava inferior.

ON March 5, the Hon. Alan de Tatton Egerton, M.P., will read a paper to the Cold Storage and Ice Association, of which he is president, at the Institution of Mechanical Engineers, on the cold stores and ice factory at Knutsford.

IT is reported that Prof. Virchow continues to make satisfactory progress towards recovery. He is now permitted to make some attempts to walk, and it is hoped that he will in time regain the full use of the injured limb.

WANT of knowledge of the principles and results of vaccination and of antitoxin treatment is responsible for many incorrect opinions and for opposition to medical research. The Vaccination League has been formed with the object of extending the knowledge of the subject of vaccination, and thus, to some extent, counteract the erroneous impressions received from pamphlets prepared by anti-vaccinationists. Among the influential names recently added to the long list of vice-presidents of the League are those of the Bishop of London, Archdeacon Sinclair and Lord Newton. It will be remembered that Lord Newton recently introduced a Bill into the House of Lords on the question of vaccination. Those who are desirous of obtaining free literature dealing with the advantages of vaccination, or of organising popular illustrated lectures on the subject in their respective districts, should apply to the secretary of the Vaccination League, 110 Strand, W.C.

THE anniversary meeting of the Geological Society was held at Burlington House on Friday last (February 21). The officers were appointed as follows:—President, Prof. C. Lapworth, F.R.S.; vice-presidents, Sir Archibald Geikie, F.R.S., Mr. J. E. Marr, F.R.S., Prof. H. A. Miers, F.R.S., and Prof. H. G. Seeley, F.R.S.; secretaries, Mr. R. S. Herries and Prof. W. W. Watts; foreign secretary, Sir John Evans, K.C.B., F.R.S.; and treasurer, Dr. W. T. Blanford, F.R.S. The following awards of medals and funds were made. The Wollaston medal to M. F. Schmidt, of St. Petersburg; the Murchison medal to Mr. F. W. Harmer; the Lyell medals to Prof. Anton Fritsch and Mr. R. Lydekker, F.R.S.; the Wollaston fund to Mr. L. J. Spencer; the Murchison fund to Mr. T. H. Holland; the Lyell geological fund to Dr. Wheelton Hind; and the Barlow-Jameson fund to Mr. W. Hutchings. The president delivered his anniversary address, which dealt chiefly with the evolution of ideas during the nineteenth century as to the genesis and classification of sedimentary and metamorphic rocks.

THE annual meeting of the Institution of Mechanical Engineers was held on Friday last. The report of the council records that the work of preparing the sixth report of the Alloys Research Committee—dealing mainly with the effect of annealing and tempering on the properties of steel—was continued in the laboratories of Sir W. C. Roberts-Austen at the Royal Mint and at the Royal College of Science until October 31; and a full report, which is now partly written, is expected to be ready during the present year. The second report of the Gas-Engine Research Committee was read and discussed at the October meeting, and the Institution has agreed to provide during the present year instruments for trials with a large experimental gas-engine which Prof. Burstall is designing to form part of the power and lighting plant in connection with the new Birmingham University Buildings. The experiments at University College, London, on the value of the steam jacket were continued during the early part of last year with the old apparatus, but were interrupted by the appointment of Prof. T. Hudson Beare to a chair in the University of Edinburgh. The apparatus has been removed from London to Edinburgh, and Prof. Beare is now designing several improvements in the valves for the admission and exhaust of the steam into the hot pots of the apparatus. As soon as these new valves are made, the experiments will be resumed, and it is hoped more satisfactory results will be obtained with this new apparatus. The series of experiments at King's College on the compound steam-jacketed engine has been completed, and Prof. David S. Capper has promised his report early this year. A second series of tests with unjacketed cylinders has been commenced, and is being carried through at the same speeds and steam pressures as the first jacketed series. Direct comparisons can then be made both with and without steam jackets. The council has joined with the councils of the Institution of Civil Engineers, the Iron and Steel Institute and the Institution of Naval Architects in forming a committee, to be called "The Engineering Standards Committee," for the purpose of recommending standard sizes for rolled sections, and other matters. The question of standardising pipe flanges, being of great importance at the present time, will be dealt with in a paper to be read before the Institution at an early meeting.

THE death is announced, at Vienna, of Dr. Emil Holub, the famous African explorer. From an obituary notice in the *Times*, we learn that Dr. Holub, who was a native of

Bohemia, was of Czech descent. He was born in the small town of Holics on October 7, 1847. After practising for a time as an apothecary, his scientific leanings and his adventurous spirit led him, at the age of twenty-five, to emigrate to South Africa. His principal inducement to explore the land beyond the Zambesi was his love of natural history, and more particularly his interest in ornithology. Indeed, the first period of seven years spent by him in South Africa was mainly devoted to ornithology and to zoology in general. On his return to Europe he took up his residence at Prague, and afterwards in Vienna, where he prepared his "Beiträge zur Ornithologie Südafricas" ("Contributions to the Ornithology of South Africa"). A little later he published "Seven Years in South Africa" and "The Colonisation of Africa." At this time he devoted himself seriously to the study of astronomy and geography, having during his first journey been greatly hampered, as he was always the first to confess and deplore, by his lack of physical and mathematical knowledge. His explorations, therefore, had been rather those of a zoologist than of a geographical explorer. Having resolved to overcome this difficulty, he set to work, and when, in 1883, he landed on African soil for the second time he was probably as well equipped as any of his predecessors in African exploration. After a little delay, Dr. Holub proceeded to the country of the Mashukulumbe, into which he penetrated further than any European had done before him. There, accompanied by his wife, he spent four years, returning to Europe in 1887. His book, entitled "From Cape Town to the Country of Mashukulumbe," which contains a record of his labours, has become a standard work. Like his former publications, it has been translated into many languages.

THE German Physical Society's publication, *Die Fortschritte der Physik*, has, under the editorship of Profs. Scheel (for pure physics) and Assmann (for cosmic physics), fairly succeeded in attaining the maximum efficiency in keeping up to date with the most recent papers, consistently with its appearance as a yearly volume. In order to accelerate further the issue of a summary of current literature, Messrs. Fried. Vieweg and Son, of Brunswick, now announce the publication, in connection with the *Fortschritte*, of a *Halbmonatliches Litteraturverzeichniss*, which will furnish the physicist at fortnightly intervals with a list of papers and books classified under the various branches of physics. The first and second numbers contain forty and twenty pages respectively. The titles only of the papers are given, so each page contains the names of some five-and-twenty different papers. The subscription price of the *Litteraturverzeichniss* is only 4 marks per annum, so it should soon find its way into the library of every physicist.

THE *Bulletin* of the French Physical Society, No. 174, describes briefly some important experiments by M. Marey on the motion of fluids studied by photography. In the case of liquids, M. Marey was successful, as long ago as 1893, in studying the motions by means of beads of the same specific gravity as the liquid. He has recently succeeded in studying the movement of air-currents past a fixed obstacle by means of smoke filaments, obtained by filtering the air-current through silk gauze with even meshes, the smoke being photographed by means of magnesium light. Where no obstacle exists, the filaments of smoke are rectilinear and parallel, while if an inclined plane be placed in the current, they will be seen to indicate the form of the stream lines, some bending round the upper and others round the lower edge. To obtain the velocity of the current at different points, a lateral oscillatory motion of ten periods per second is given to the screen, when the smoke filaments assume a sinusoidal form which is preserved throughout their path and the distance between the inflexions at any point determines the velocity. When the experiments were repeated under identical conditions, the two images were found to agree to such an extent as to be capable of superposition.

IN connection with the wreck of *Santos Dumont* No. 6, Dr. J. Y. Buchanan, F.R.S., has written a letter to the *Times* which may serve to correct any false impressions that may have been formed as to the value or general conclusions of the experiments. It is pointed out that "to M. Dumont himself every fresh ascent, whether the public term it a success or a failure, is full of lessons on a quantity of matters of detail of which the uninitiated can have no perception. Indeed, the more complete the apparent failure, the greater is the value of the experience to the air pilot, provided he escape so as to be able to utilise the experience himself." Since Dr. Buchanan arrived at Monaco, M. Dumont has taken his balloon out three times. The first time (on February 10) the balloon completely outstripped the Prince of Monaco's launch, and was even estimated to achieve 15 knots relative to the ground, going against a breeze. But "the most striking and at the same time unfavourable feature was the heavy pitching of the balloon, which at times attained an amplitude of not far from 45° on each side the vertical." On the 11th, M. Dumont performed his most successful journey in the direction of Cap Martin and back, the balloon pitching much less than previously. The accident which occurred on the 14th appears to have been mainly due to this pitching. "Arrived abreast the pigeon-shooting ground, the pitching became more violent, and the balloon rose, taking the guide-rope, which usually trails on the surface of the water, entirely out of the water and to a height of fifty yards or more above it. The situation was now becoming critical. In pitching, the balloon came to be standing very nearly vertically, first on one end and then on the other." M. Dumont appears then to have let out gas, which had the effect of causing the rear and lower end to collapse, and the rudder was thereby rendered useless. From this time until M. Dumont was rescued, wet and bedraggled, from the wreck, frequent photographs were taken showing the form assumed by the balloon during its gradual deflation. Two conclusions are drawn from the experiments; firstly, that the pitching must be prevented by the application of aëroplanes or side pieces performing the functions of bilge keels, or by other means, and, secondly, the great difficulty attaching to the ellipsoidal balloon as compared with the typical one of spherical or more strictly pear-shaped form, in that the former tends to revert to the spherical shape as soon as it is somewhat deflated, while the latter better preserves its natural form in shrinking.

A WRITER in the *Dumfries and Galloway Standard and Advertiser* (February 12) directs attention to a curious anticipation of a magnetic means of communication contained in the following paragraph from the *Spectator* of December 6, 1797:—"Strada, in one of his prolusions, gives an account of a chimerical correspondence between two friends by the help of a certain loadstone, which had such virtue in it that if it touched two several needles, when one of the needles so touched began to move, the other, though at never so great a distance, moved at the same time, and in the same manner. He tells us that the two friends, being each of them possessed of one of these needles, made a kind of a dial plate, inscribing it with the four and twenty letters, in the same manner as the hours of the day are marked upon the ordinary dial plate. They then fixed one of the needles on each side of these plates in such a manner that it could move round without impediment so as to touch any of the four and twenty letters. Upon their separating from one another into different countries, they agreed to withdraw themselves punctually into their closets at a certain hour of the day, and to converse with one another by means of this their invention. Accordingly, when they were some hundreds of miles

asunder, each of them shut himself up in his closet at the time appointed and immediately cast his eyes upon his dial plate. If he had a mind to write anything to his friend, he directed his needle to every letter that formed the words which he had occasion for, making a little pause at the end of every word or sentence to avoid confusion. The friend, in the meanwhile, saw his own sympathetic needle moving of itself to every letter which that of his correspondent pointed at. By this means they talked together across a whole continent, and conveyed their thoughts to one another in an instant over cities or mountains, seas or deserts."

PROF. A. AGASSIZ and his party have returned to Colombo, after spending a few weeks in the exploration of the Maldives. From the *Ceylon Observer* we learn that about three hundred photographs were taken, principally of coral-reef subjects. The principal work done was the sounding of the channels between the lagoons and the development of the plateau on which the atolls of the Maldives have been formed. The principal atolls are separated by comparatively shallow water in the central part of the group, while towards the south, between Hadumati and Suvadiva and Addu, the depths are very much greater—nearer a thousand fathoms. A line was run to the westward of Ari Atoll into fifteen hundred fathoms, and one to the southward of South Male into twelve hundred fathoms, showing that the plateau of the Maldives is much steeper on the west than on the east face. Soundings were also taken between the northern Maldives and Colombo, and they show that the Maldives are separated from the Indian continental slope by a deep bank of the ocean of more than fifteen hundred fathoms in depth. The atolls of the Maldives are said to exhibit the most simple and primitive conditions for the formation of atolls which are found anywhere except in some parts of the Yucatan plateau in the West Indies. Atolls can be found in all stages of growth, from a mere bank rising to a few feet above the plateau to banks within five or six fathoms from the surface or to banks which have just reached the surface and on which sandbanks or islets are beginning to forms. Prof. Agassiz says that one reason for the success of his expedition is that the charts published more than seventy years ago are as accurate to-day as they were then. The only changes noticed were changes such as the washing away of banks or the formation of banks since the charts were published; but these are changes without any special importance.

WE have received the Report of the Meteorological Commission of the Cape of Good Hope for the year 1900. The Commission has had to contend with considerable difficulty owing to the irruption of hostile bands into Cape Colony and the wanton destruction of many instruments. Nevertheless, it is able to report that the interest shown in the subject both by observers and the general public continues to grow, and that observations have been restarted at Johannesburg and Kimberley. Compared with the previous year, there has been a considerable increase in the number of observers, especially at rain-gauge stations, which now number 447. An investigation is being made into the connection between the weather and the plague in Cape Town. The result goes to show that each marked rise in temperature was followed in a period of from ten to fourteen days by an increase in the number of plague cases. The Commission has also taken up the investigation of ocean currents with the cooperation of the Union-Castle Steam-ship Company, whose captains are instructed to throw bottles overboard at fourteen different points along the coast. Among various papers which have recently been read before the South African Philosophical Society may be mentioned one of especial interest on some periodical changes in the rainfall at the Royal Observatory, since 1841, by Prof. J. T. Morrison, in which evidence is shown of two prevailing periodicities running simultaneously through the monthly amounts, and completing themselves in ten years and in slightly over nine years respectively. The author also finds a well-marked periodicity of about sixty years, but its exact period has not yet been determined.

THE Meteorological Office pilot chart of the North Atlantic and Mediterranean for the month of March states that, although there is a general diminution in the strength of the winds at this season, gales are still of frequent occurrence, especially on the western half of the ocean, where, over a considerable area, the frequency is from 25 to 36 per cent. This locality is indicated on the inset chart of mean barometric pressure by a closing up of the isobars. The prevalent north-easterly winds in the neighbourhood of the British Isles are associated with the dipping of the isobars south-eastwards towards Spain. On the Gulf of Mexico the "northers" are becoming less frequent, but they undergo certain important modifications. They are shorter in duration and are accompanied by finer weather, but they blow with greater violence during the first twenty-four hours of their continuance and draw less to the north-east. Fog on the Banks having reached its minimum in February is now spreading east and west, and mariners are cautioned against hugging the coasts of the United States during the prevalence of east winds, and particularly gales, as the low shores are then hidden in fog. Two inset charts are given to illustrate the north-easterly type of weather over western Europe, one being the blizzard of March, 1891, when many of our southern counties were buried deep under snow. One result of the presence of these spring north-east winds is seen in their marked influence on the currents. Not only is there a south-westerly set traceable from the Channel soundings, but even northward of the 50th parallel there is a westerly flow to about 22° W., where it curves to southward and south-eastward and merges in the south-westerly set near the 40th parallel. The Gulf Stream water is thus kept away from our south-western shores at this season, but out on the ocean its flow can be traced north-eastward to the neighbourhood of Rockall. No ice appears to have been reported since the early part of December.

THE issue of the pilot chart referred to in the foregoing note completes the series for a whole year, and investigators have now at their service a most valuable summary of the salient features of the various elements month by month. The circulation of the ocean waters will attract most attention, because the currents of the Atlantic have never before been published for each of the twelve months, and as the results here given are based on observations extending over the very long period of sixty-five years, they are as complete as can be hoped for. Commander Hepworth has been singularly successful in his selections of weather types and other matter for the several months, many of them being justified in the course of the period covered, such, for instance, as the northerlies in May, the summer thunderstorms, the September hurricane near the Cape Verde Islands, the recent exceptionally high barometer (31·11 in.), and the dust storm off north-west Africa in January, &c. Reports from different parts of western Europe indicate very clearly that the sand precipitated in South Wales and the south-west of England on January 22 and 23 had travelled northward from the sandstorm experienced about the Canaries and Madeira on the 17th and 18th, when an easterly gale was blowing from the African mainland.

SO comparatively easy has it now become to obtain good photographs by means of flashlight that pictures of places situated under the level of the earth's surface are not uncommon. So interesting are some of these underground passages, caves and grottoes, and so great is the chance that as time goes on they will undoubtedly be

deprived of their natural charms, it seems only right that their features should be at once rendered permanent by means of photography and kept as records for future generations. As pointed out in the current number of the *British Journal of Photography* (February 14), we have not necessarily to leave our own country in search of such subterranean cavities, for we have in Yorkshire, Derbyshire, Thanet and other parts of the country grottoes which are well worth seeing and photographing. Why, then, should not these British caves be treated in the same way as has recently been done for the famous grotto of Han? This subterranean paradise, as it has been called, has lately been photographed with great success and the pictures published in a booklet entitled "The Wonders of the Grotto of Han." In some cases, magnesium light was used as an illuminant, while in others the electric light which adorns the principal galleries of the cavern was sufficient. Even if it were impossible to get sufficient light for such dark interiors by flash, the above-mentioned journal suggests that there is no reason why a time exposure should not be made, making use of a pyrotechnic composition with magnesium or aluminium as its base.

MESSRS. W. M. MORDEY and B. M. Jenkin, in their paper on electrical traction on railways, which was read before the Institution of Civil Engineers last week, dealt with the relative merits of direct-current, alternate-current and composite systems. The present time is opportune for such a paper, as the electrification of some of the larger railways is being more or less seriously discussed. In this country, as the recent Inner Circle arbitration showed, direct-current driving is favoured, the system being generally a composite one, with generation of alternating current at high voltage and conversion to direct-current at 500 volts at substations. On the Continent, as the authors pointed out, there is a tendency to work out the more difficult problems in traction work by the use of three-phase alternating current for both transmission and driving. After summing up the requirements that should be met by any general system of electrical railway working, the authors concluded that the distribution of power is best effected by single-phase alternating current. The Ward Leonard system of utilising such current was then discussed in detail; by this the current is supplied to a single-phase motor on the train which drives a dynamo, which in turn drives the direct-current train motor. This method, though it appears complex, is, they consider, the one best satisfying all the conditions for a general electric traction system.

MR. W. L. SCLATER'S illustrated notice of that remarkable bird, the ground-hornbill (*Bucorax cafer*) of South Africa, which appears in the February issue of the *Zoologist*, will be read with interest by ornithologists. These birds, which are generally seen in the open, live entirely on the ground, and wander about in parties of five or six. It is believed that several females lay in the same nest, which is situated in a hole high up in the stem of a tree.

TO the *Revue générale des Sciences* for September 15, Prof. A. Forel contributes a long article on the psychic faculties of insects. According to the author, these creatures are certainly endowed with four senses, namely sight, smell, taste and touch, the possession of hearing being doubtful. Some writers attribute to them a "photodermatic" sense, but this is merely a modification of touch. After describing the location of each of these senses, the author proceeds to discuss the powers of perception, volition and "sentiment" possessed by insects, concluding with a comparison between their intellect and that of man.

THE February number of the *Zoologist* contains Mr. T. Southwell's account of sealing and whaling for the past year. For the first time for an unknown period, no British whaler visited the sea between Greenland and Spitzbergen. Davis Strait, on the other hand, was visited by several vessels, and whales were by no means scarce, although, owing to bad weather, captures were not numerous and two whales were lost after being killed. One whale with whalebone close on twelve feet long was secured. The price of whalebone during the season was 1450*l.* per ton, but it is now said that 2000*l.* is being asked. The Newfoundland sealing was fairly successful, and was remarkable for the early date at which the vessels completed their cargoes. The Gulf sealing, on the contrary, was a practical failure.

AN influential committee has been appointed to promote a "nature-study" exhibition to be held in London about the end of July. It is suggested that the exhibition should be open to urban and rural elementary day schools, continuation schools, higher-grade schools (boys and girls), Home Office schools, secondary schools (boys and girls), and other institutions and colleges, and that prizes or certificates should be offered in each class for (1) The best collection of common dried plants, injurious insects, &c., apparatus for class lessons, drawings made in class of natural objects, home-made maps with a school as centre, showing features of interest within a radius of two or three miles of the school, note-books, natural history calendars, plans of gardens, photographs, models in clay or plasticine of natural objects, plants grown in boxes and pots, and rustic carpentry. Schools would not be restricted to these exhibits, nor would they be required to send all of them. Teachers would use their own discretion in sending what they believe will most fully illustrate their courses in "nature-study." Specimens of rare plants would not be asked for, and the uprooting of any plant would be especially forbidden. (2) The best individual exhibit of one pupil's work. (3) The best scheme of instruction and descriptive account of work, methods, &c. There should be no difficulty in obtaining the necessary funds for such an excellent object.

THE discourse on "The Discovery of the Future," delivered at the Royal Institution on January 24 by Mr. H. G. Wells, and printed in our issue of February 6, has been published in book form by Mr. T. Fisher Unwin.

MR. W. A. SHENSTONE'S little book on "The Methods of Glass Blowing" (Longmans, Green and Co.) is favourably known to all who have cultivated the art for the purposes of constructing physical and chemical apparatus and accessories. The practical hints on glass-blowing contained in the book are the result of long practice at the blow-pipe, and experience of the requirements of laboratories. The fourth edition of the book, which has just been published, contains a new chapter in which Mr. Shenstone describes the methods of working silica in the oxy-gas flame, a subject to which he has given particular attention.

THE presidential address delivered at the Philadelphia meeting of the Chemical Society by Prof. F. W. Clarke appears in a recent number of *Science*. The address deals with the development of chemistry, and is an interesting discussion of the progress and prospects of chemical science. Prof. Clarke considers that the chief need of chemistry at the present time is the better organisation of research. Whilst fully appreciating the great work that is done by individuals working independently in the field of science, he thinks that collaboration and systematisation are urgently required. He maintains that either by public expense or by private enterprise, laboratories for research should be established in all civilised countries. By conference between them, the work should be so adjusted as to avoid repetition, each one reinforcing the others. Their primary function should be to perform the drudgery of science, to undertake the tedious, laborious, elaborate investigations

from which the solitary worker shrinks, but which are, nevertheless, essential to the development of chemistry. Brilliant discoveries might be made in them, but incidentally, and not as their main purpose.

THE table of atomic weights issued annually by the international committee appears in the January number of the *Berichte*, and the table, based upon oxygen = 16, is unaccompanied by the didactic table with hydrogen = 1. The withdrawal of the didactic table is in accordance with a widely expressed wish. It is generally felt that if oxygen is to be taken as 16 for any purpose it should be taken as 16 for all purposes. Discussing this subject in a paper recently contributed to the American Society of Sciences and Arts, Prof. Richards made a strong appeal to chemists to conform to the decision of the international committee. He pointed out that oxygen has actually served as the experimental standard of reference in a great majority of cases, that the great bulk of valuable work has already been published on the basis oxygen = 16·000, and that the use of this standard involves no important didactic difficulties. He contends that the decision of the representatives of the international committee is in itself an important reason for adopting this standard, and that uniformity of usage is more important than any of the special advantages claimed by either side in the discussion. The only alterations of atomic weights in this year's table are of calcium from 40 to 40·1, iron from 56 to 55·9, and tellurium from 127 to 127·6.

THE additions to the Zoological Society's Gardens during the past week include two Guinea Baboons (*Cynocephalus sphinx*), a Red-footed Ground Squirrel (*Xerus erythropus*) from West Africa, presented by Captain R. H. Wilford; a Snow Leopard (*Felis uncia*) from Northern India, presented by Captain H. Nicholl; two Half-collared Turtle Doves (*Turtur semitorquatus*) from West Africa, presented by Captain Thorne; a Ring-necked Pheasant (*Phasianus torquatus*) from China, presented by Mr. B. Tufnell; seven Black-headed Gulls (*Larus ridibundus*), a Common Gull (*Larus canus*), European, presented by Mr. E. J. W. Eldred; a Green Monkey (*Cercopithecus callitrichus*), an Erxleben's Monkey (*Cercopithecus erxlebeni*), eight West African Love-Birds (*Agapornis pullaria*) from West Africa, a Greater Sulphur-crested Cockatoo (*Cacatua galerita*) from Australia, a Levaillant's Amazon (*Chrysotis levaillanti*) from Mexico, ten Common Toads (*Bufo vulgaris*), European, a Loggerhead Turtle (*Thalassochelys caretta*) from Tropical Seas.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN MARCH.

Mar. 3. 22h. Vesta in conjunction with the moon. Vesta 0° 35′ S.
5. 15h. Saturn in conjunction with the moon. Saturn 5° 1′ S.
6. 14h. Jupiter in conjunction with the moon. Jupiter 5° 41′ S.
7. 7h. Venus in conjunction with the moon. Venus 2° 11′ N.
12. 10h. 12m. Minimum of Algol (β Persei).
15. 7h. 1m. Minimum of Algol (β Persei).
15. Venus. Illuminated portion of disc = 0·198, Mars = 1·000.
17. 2h. 0m. Mercury at greatest elongation (27° 41′ W.).
17. 9h. 19m. to 10h. 16m. Moon occults 26 Geminorum (mag. 5·1).
18. 5h. 48m. to 6h. 14m. Moon occults 68 Geminorum (mag. 5·0).
18. 15h. 19m. to 18h. 58m. Transit of Jupiter's Sat. III.
20. 8h. 27m. to 9h. 43m. Moon occults ω Leonis (mag. 5·6).
20. 19h. 0m. Venus at maximum brilliancy.
Mar. 21. 1h. 0m. Sun enters Aries. Spring commences.
21. Saturn. Outer minor axis of outer ring = 13″·75.
22. 11h. 19m. to 12h. 24m. Moon occults p^5 Leonis (mag. 5·5).
28. 13h. 41m. to 15h. 0m. Moon occults ν Scorpii (mag. 4·5).
29. 13h. Mars in conjunction with sun.

OBSERVATIONS OF 900 DOUBLE AND MULTIPLE STARS.—The first of the astronomical series of publications from the University of Pennsylvania consists of the measures of 900 double and multiple stars made by Prof. Doolittle with the 18-inch refractor of the Flower Observatory. These observations were made during the period 1897 January 1 and 1900 October 15. In all cases a power of 592 diameters was employed. Twenty-two of the stars are now catalogued for the first time, having been discovered during the observation of neighbouring doubles.

The 18-inch objective is the largest lens made by Brashear up to the present time, and has given every satisfaction, both as to resolving and light-grasping power. The mounting, by Warner and Swasey, is of similar construction to the Lick and Yerkes instruments (*Publications of the University of Pennsylvania, Astronomical Series*, vol. i. part iii.)

OBSERVATIONS OF 194 DOUBLE STARS.—*Bulletin* No. 11 from the Lick Observatory contains a list of observations made by Mr. R. G. Aitken during 1900 and 1901 with the 36-inch and 12-inch refractors. Many of the stars are difficult pairs, and in most cases the 36-inch telescope was employed, with powers ranging from 1000–2400.

RADIO-ACTIVITY AND THE ELECTRON THEORY.[1]

ELECTRONS emanating from radio-active bodies behave like material particles, and are impeded by the molecules of the surrounding medium, in contrast with ether waves, which are not thus affected except by absorption. It is not difficult to put these indications to test. A pair of shallow cells, A B (Fig. 1), 1·5 mm. deep and 25 mm. square, were made by cementing slips of glass to a thick glass plate. The cells were filled to the same depth with a radio-active substance chiefly containing actinium.[2] Over cell A was placed a piece of thick lead pipe, 28 mm. high and 25 mm. internal diameter, to ensure that any emanations from the active substance in A would be confined to the inside of the hollow cylinder. The radio-active substance in B was freely exposed to the air, save for a pillar of lead at C, to support the sensitive film. A sensitive film was laid horizontally over the cylinder and support C. On the film was a plate of glass, and cylinder and film were pressed together by heavy weights. The whole was covered in a light-tight box and put in a dark cupboard.

At the end of forty-eight hours the film was removed and developed. There was a strong action shown over cell A (the one covered by the lead cylinder), but over B, the cell exposed to the air, there was no visible impression. Measured in Mr. Chapman Jones's "Opacity Meter"[3] the results were:—

Image over cylinder—Opacity log.[4] = ·79; Opacity[5] = 6·17.

The experiment was repeated, using the same apparatus, but a different preparation of actinium. In this case the exposure was for seventy-two hours. As before, there was a strong impression over cell A and none over cell B. The figures were:—

Opacity log. = ·89; Opacity = 7·71.

These experiments indicate that the electrons from the radio-active agent, chiefly actinium, partake of the properties of a fog or mist of material particles, capable of diffusing away in the free air like odoriferous particles, when not kept in by a thick metal screen.

A further experiment was now tried with the same apparatus, the agent a strongly active radium and barium bromide. This material being self-luminous, a sheet of black paper was placed

1 By Sir William Crookes, F.R.S. A Paper read before the Royal Society on February 6.
2 The body I called Uranium X in my Royal Society paper, May 10, 1900, has since proved to be M. Debierne's Actinium.
3 *The Photographic Journal*, vol. xx. p. 86, December 21, 1895.
4 The opacity logarithm represents the density of the image, absolute density being represented by 2·00.
5 The "opacity" is the whole number corresponding to the "opacity log." The "opacity" is directly proportional to the photographic energy acting on the sensitive surface.

immediately over it, so that nothing but emanations capable of passing through the opaque paper would be subject to experiment. Afrer four hours' exposure in total darkness, the film was developed. A good circular patch was obtained over cell A, and a faint diffused darkening showed over the rest of the film, darker at the spot immediately over cell B, fading away at the sides as the distance became greater. That this action was due to the material in the open cell B, and not to general fog over the plate, was seen by the clearness of the film where covered by the lead, and where shadows were thrown by the lead cylinder and pillar.

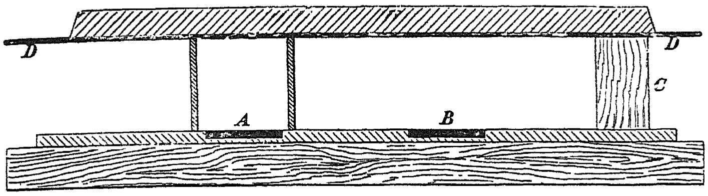

Fig. 1—Elevation.

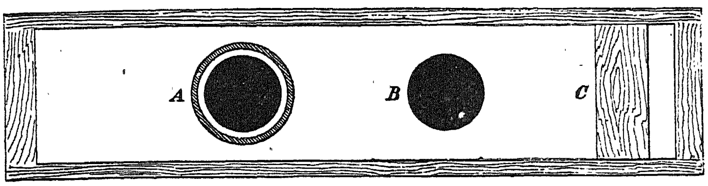

Fig. 1.—Plan.

Circles of the same diameter were drawn round the dark impression over A, and round the darkest part of the impression over cell B. Measurements were taken of different parts of the spaces enclosed in these circles, and the mean of all these came out—

Circle over cell A—Opacity log. = ·53; Opacity = 3·39.
Circle over cell B—Opacity log. = ·32; Opacity = 2·09.
Ratio B/A = ·62.

The experiment was repeated, with the addition of a sheet of aluminium, 0·2 mm. thick, under the black paper, the electrons now having to pass through both paper and metal before reaching the film.

The exposure was for six hours, and the appearance on development was very similar to the last: a dark disc over the protected cell A, and a diffused action over the other part of the film, except in the shadow of the lead supports. Measurements as on the previous occasion gave the following results:—

Circle over cell A—Opacity log. = ·78;
Opacity = 6·03.
Circle over cell B—Opacity log. = ·48;
Opacity = 3·02.
Ratio B/A = ·5.

Finally, I tried polonium subnitrate, which gives off emanations hardly capable of passing through any screen, and greatly obstructed by a few centimetres of air.

The apparatus was substantially the same as the one just described, with the modification that the lead cylinder was 12 mm. high, and at the other end a rod of glass 12 mm. high was used to support the film. The reduced height was chosen, experience showing that polonium emanations have great difficulty in penetrating many millimetres through air. The exposure was seven days, at the end of which time the film was developed. Over cell A a dark disc sharply defined the inside of the cylinder, while over cell B was a hazy diffused patch which to the eye looked much the fainter of the two. But measurements of patch A, and of a disc over cell B of the same size as A, showed that the opacities in each case were practically identical, as shown by the following figures:—

Circle over cell A—Opacity log. = ·74; Opacity = 5·49.
Circle over cell B—Opacity log. = ·76; Opacity = 5·75.
Ratio B/A = 1·05.

A repetition of the experiment, taking the mean of five concordant results, gave the same opacities as before.

Without proving that the emanations from polonium are less material than those from actinium and radium, this experiment shows that their behaviour is entirely different as regards diffusibility through air. Whether this is due to the larger mass of the individual particles, or to the less distance they have to travel (12 mm. as against 28 mm. in the case of actinium and radium), or to some other cause, further experiments must decide.

Dr. Rutherford shows that air which has remained for some time in the neighbourhood of thoria and then is carried in a current to a distance retains its property of communicating radio-activity to other bodies. He explains these phenomena by supposing that thoria gives off a special kind of emanation capable of being conveyed by the air, and that this is the cause of the induced radio-activity.

To ascertain if the electrons or corpuscles from radium also possess the property of being carried along in a current of air I fitted up an apparatus shown in Fig. 2. A, B, and C are three brass tubes closed at the lower end and cemented with paraffin to a wooden block. The upper ends were accurately ground to a level surface and then coated with a thin layer of paraffin wax. Holes were drilled in B and C, to admit glass tubes, cemented air-tight into the cylinders, as shown in the figure. The upper end of the tube in B was closed with a plug of cotton-wool, and the outer end in C was connected to a water-pump, so that when the cylinders were closed at the top a current of air was drawn through B and C. As the radium compound was self-luminous, discs of thin aluminium foil were placed over cylinders A and B to cut off the luminous rays. A sensitive film was laid on the three cylinders over the aluminium, and it was tightly pressed down by a heavy weight, the contact between the film and the tops of the cylinders being sufficient to make the whole air tight. At the bottom of A and B a radium compound was placed, equal weights and equal surface in each. The whole

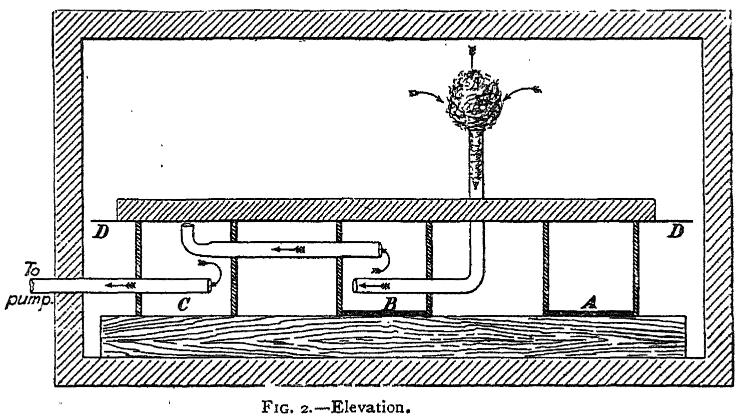

FIG. 2.—Elevation.

was put into a light-tight box, and air drawn through. The cylinder A was used only as a standard. The air passing into B was expected to carry along with it some of the corpuscles emitted from the active material at the bottom; and the inlet tube in C was turned up at the end, so that the stream of corpuscles-laden air should impinge on the surface of the centre of the film on C, and if it carried with it any radio-active properties the result should be seen on development, by the production of a dark patch. If, however, the air carried no corpuscles, there would be no image on the sensitive film over C.

The experiment was continued for eleven hours, 120 litres of air having passed through in the time.

On development and measuring the resulting images, the following figures were obtained :—

Circle over cell A—Opacity log. = ·342 ; Opacity = 2·20.
Circle over cell B—Opacity log. = ·178 ; Opacity = 1·51.
Circle over cell C—Opacity log. = ·025 ; Opacity = ·11.
Ratio B/A = ·68.

It thus appears that a current of air passed over the surface of a radium compound carries with it a certain proportion of the corpuscles. This is proved by the diminished photographic action in the second cell, slightly confirmed by the evidence that some few of the corpuscles so carried away get to the sensitive film on cell C. Judging from our slender knowledge of the properties of free electrons, it is highly probable that they will not easily turn a corner, but cling to the sides of the tube through which they are being led. On the other hand, the constant collisions with the atoms of air may reduce their initial mobility almost to a vanishing point before they have travelled along the tube between B and C, and then they would be carried along with the air.

The experiment was repeated, using a preparation of actinium (Uranium X). It was kept going for seventy-two hours, during which time 750 litres of air were drawn through the apparatus. On development and measurement, the following results were obtained :—

Circle over cell A—Opacity log. = ·99 ; Opacity = 9·78.
Circle over cell B—Opacity log. = ·67 ; Opacity = 4·68.
Circle over cell C—Opacity log. = ·25 ; Opacity = 1·78.

Here then the results agree with those tried with radium compounds ; that corpuscles are carried by a current of air from cell B, through the connecting tube to cell C. They also confirm those of Dr. Rutherford—who finds that thorium emanations travel in a current of air while retaining their activity—and of P. Curie and A. Debierne, who show that induced radio-activity can be transmitted through capillary tubes, of an internal diameter of ·1 mm. and 75 cm. in length, bent once at right angles.

I have not obtained, however, a similar result with the emanations from hydrogen peroxide. As shown by Dr. Russell, this substance has a strong action on a sensitive photographic plate. The emanation from a bottle half full of hydrogen peroxide acts strongly on a sensitive film laid over the open mouth of the bottle for twenty-four hours, while there is no action in seventy-two hours if a U-shaped tube passed through the cork of the bottle and the sensitive film is put close to the open end of the tube. Dr. Russell tells me his observations confirm my experiments.

A highly active self-luminous radium compound loses some of its power on long exposure to the ordinary air of the laboratory. When enclosed in glass, the glass soon assumes a pink colour. If, however, the radium compound is sealed in vacuo in a *quartz* tube, no coloration takes place, and I can detect no diminution of energy even in twelve months.

Electrons from radium will pass through aluminium and a considerable length of air and affect a sensitive film.[1] Experiments on this point were tried with polonium, and it was found that air offered great obstruction.

The electron theory explains a fact which has long puzzled experimentalists. It is well known that if a coin is laid on a sensitive plate in perfect darkness and connected with one pole of an induction coil for a few seconds and then developed, an image can be obtained of the raised parts of the coin. This has generally been explained by saying that the electrified stream of air, or the "brush discharge," affects the film like light.

But Mr. F. Sanford (NATURE, vol. lv. p. 485) shows that coins embedded in the centre of a block of paraffin 2 cm. thick, where they could not send off streams of electrified air, can still be photographed by means of the induction coil. In these circumstances it is probable that electrons are the agents, as electrons will easily pass through paraffin wax from the coin to the sensitive plate, when the coin is connected with the negative pole of an induction coil, the other pole being connected with a metal plate placed below the wax block.

[1] Using an active compound of radium, I have obtained an impression on a sensitive film, through a penny-piece.

Hitherto we have been dealing with negative electrons—a free positive electron at present is unknown. In a paper communicated to the Royal Society, December, 1890 (*Phil. Trans.*, 1901, A, vol. cxcvi. p. 525), the Hon. R. J. Strutt offers a suggestion as to positive ions which in a satisfactory manner appears to explain much that hitherto has been left doubtful, not to say contradictory.

He adopts the generally recognised theory that the deflectable Becquerel rays consist of a stream of negative corpuscles with enormous velocities proceeding from the radio-active body. But there are two kinds of Becquerel rays, one deflectable and penetrating, the other non-deflectable and easily absorbable. Mr. Strutt considers that these non-deflectable rays are positive ions moving in a stream from the radio-active body.

He says :—"We know that the positive ions in gases carry the same charge as the negative, and that they have an enormously greater mass. Unless, therefore, their velocity is smaller out of all proportion than the negative ions, it is to be expected that they will be much less easily deflected by the magnet. . . . Next it may be noticed that the smaller penetrating power would be well accounted for by the size of the positive ions, which would, of course, make more collisions with the molecules of the surrounding gas than the much smaller negative ions."

Of the three radio-active bodies, radium, actinium and polonium, actinium appears to emit corpuscles almost entirely of the penetrating, deflectable kind, polonium rays of the non-deflectable, non-penetrating kind, whilst radium emits rays of both kinds.

On the above hypothesis, corpuscles from polonium might consist of the heavy positive ions: to test the accuracy of this inference experiments are now in progress.

Some curious and far-reaching inferences may be drawn from Mr. Strutt's view, supposing it to be correct, that positive as well as negative corpuscles will fly off from a radio-active body. In a paper "On Electrical Evaporation" (*Roy. Soc. Proc.*, vol. l. p. 88, June, 1891) I showed that many bodies, such as silver, gold, platinum, &c., usually considered non-volatile at ordinary temperatures, easily volatilise in a vacuum if connected with the negative pole of an induction coil, remaining fixed when connected with the positive pole. This phenomenon was first observed by Dr. Wright, of Yale College, and was applied by him for the production of mirrors for physical apparatus. It is shown by experiments that the action in the vacuum tube is of two kinds. A silver pole was used, and near it, in front, was a sheet of mica with a hole in its centre. The vacuum was very high (P = 0·00068 mm.), and when the poles were connected with the coil, the silver being negative, electrons shot from it in all directions, and passing through the hole in the mica screen, formed a bright phosphorescent patch on the opposite side of the bulb. The action of the coil was continued for some hours, to volatilise a certain portion of the silver. On subsequent examination it was found that silver had been deposited only on the mica screen and in the immediate neighbourhood of the pole, the far end of the bulb, at the spot which had been glowing for hours from the impact of electrons, being free from silver deposit. Here then are two simultaneous actions. Electrons, or, as I once called them, "radiant matter," shot from the negative pole and caused the glass against which they struck to glow with phosphorescent light. Simultaneously the heavy positive ions of silver, freed from their negative electrons, or under the influence of the electrical stress, likewise flew off, and were deposited in the metallic state near the pole.

During the course of my experiments a curious circumstance was observed, which deserves record as it may elucidate some of these obscure phenomena. While the volatilisation of the silver pole is rapidly proceeding, the metal glows as if red-hot. This "red heat" is superficial only. The metal instantly assumes, or loses, the appearance of red-heat the moment the current is turned on or off, showing that the high temperature does not penetrate below the surface. The volatilisation of the positive ions is confined to the surface and the surface glow is connected with that action. If instead of silver, a good conductor of heat, I take diamond, a bad conductor, the surface layers are changed sufficiently to convert them into a form of graphite, which from its great resistance to oxidising agents cannot have been formed at a lower temperature than 3600° C.

THE MILROY LECTURES ON TYPHOID FEVER.

PROF. CORFIELD gave the first of his course of Milroy Lectures on typhoid fever at the Royal College of Physicians on Thursday last.

After an introduction, in which he defended the name typhoid fever as that used by Louis and Jenner, and as being the least objectionable name to give to the disease, and pointing out that the name of enteric fever is a bad one, not only because it gives the name to a general disease from a particular lesion, but because it suggests the false idea that the disease is due to that lesion, he proceeded to give a short history of the subject from the beginning of the last century, first introducing a hitherto unknown author, Dr. Christopher Mayr, of Vienna, an unopened copy of whose Latin work on fevers, published in Vienna in 1806, he had found in the library of the Royal Medical and Chirurgical Society of London. He stated that there is no other copy of this book known in London, whether in the British Museum or anywhere else, and that the leaves had not been separated when he found it. This author gives an admirable classification of fevers into genera and species, the different varieties of typhus forming his second genus, and including typhus fever and the oriental plague, which were confused together until long after that time, the occidental plague or American yellow fever, all of which he regarded as contagious, and three varieties which he regarded as non-contagious and which were evidently, from his excellent description, varieties of typhoid fever.

This author also gave a most interesting disquisition on the contagion and on the causes of these diseases. It is remarkable also to note that he includes phthisis pulmonalis among the fevers, though he does not say whether he regards it as contagious or not.

Dr. Corfield then gave an account of the work and views of MM. Louis, Chomel, Gaultier de Clanbry, Montault, Rochoux, and other French physicians, some of whom considered typhus and typhoid as the same disease and others as different diseases.

After alluding to the work of a number of other investigators, especially Dr. Lombard, of Geneva, and Dr. Shuttuck, of Boston, he gave an account of an important paper, read by Dr H. C. Barlow before the Parisian Medical Society on February 6, 1840, on the distinction between typhus and typhoid fevers. In this paper Dr. Barlow described the differences between the two diseases, and decided positively that they were quite distinct from one another.

Two months after this, Dr. Alexander P. Stewart also read a paper on the same subject before the Parisian Medical Society, but, contrary to the opinion generally held, he did not advance the knowledge of the subject in any way by his paper, and, in fact, did not lead us as far as Dr. Barlow had already done.

The work of Prof. Forget, of Paris, on follicular enteritis (even a worse name for the disease than enteric fever) was next alluded to, it being quite clear that Prof. Forget thoroughly understood what typhoid fever was and that it was a different disease from typhus.

Such was the position when Dr. William Jenner (afterwards Sir William Jenner, Bart., G.C.B., president of the Royal College of Physicians) undertook the investigation of the question. As he had been resident medical officer of the London Fever Hospital, he had had an excellent opportunity, of which he made the best use, of observing cases, both of typhus and typhoid fevers, and in 1849 he published his admirable paper on the identity or non-identity of those diseases. He proved to a demonstration that they were different diseases, and in a subsequent paper also proved that without a doubt their causes were different.

It was reserved, however, for Dr. Charles Murchison, in his able paper read before the Royal Medical and Chirurgical Society of London in 1858, to demonstrate that typhoid fever is caused in some way or other by water, air and soil contaminated with foul organic matters. In his great treatise on the continued fevers of Great Britain, he maintained that the poisons of those diseases were generated *de novo*; that of typhoid fever from decomposing excrement.

In 1873, Dr. William Budd produced his masterly work on the disease, proving that "typhoid fever is in its essence a contagious or self-propagating fever."

Dr. Corfield finally quoted from his own paper, "On the alleged Spontaneous Production of the Poison of Enteric Fever," read before the Epidemiological Society in March, 1874, when he combated the views of Dr. Murchison and maintained that the disease was infectious and had a special poison, which was not generated *de novo*, but was always derived from a previous case of typhoid fever. The correctness of this view has now been established by the discovery of the organism peculiar to the disease.

VESSELS WITH TURBINE MACHINERY.

THE introduction of the Parsons marine steam turbine into practice has extended ever since the time the *Turbinia* showed her marvellous qualities for speed, and was followed by the two torpedo boat destroyers, H.M.S. *Viper* and H.M.S. *Cobra*, which broke all previous records with a speed above 35 knots. The next steamer thus equipped was the *King Edward*, an excursion steamer plying on the Fairlie-Campbeltown route, and being the pioneer vessel belonging to the mercantile marine fitted with turbines, created a considerable interest at the time. The *King Edward* has now undergone a season's running, and (says *Engineering*, January 24) in order thoroughly to test her turbine machinery and coal consumption, data have been tabulated from her and also from the Clyde passenger paddle steamer of the same size named *The Duchess of Hamilton*, thus giving a comparative statement of the two vessels for the "running" throughout the season. The table is as follows:—

Comparative Statement of Speed, Mileage and Coal Consumption of the Paddle Steamer "Duchess of Hamilton" and the S.S. "King Edward."

	Duchess of Hamilton.	*King Edward.*
Total coal	1758 tons 13 cwt.	1429 tons 16 cwt.
Miles run	15,604	12,116
,, per ton...	8·87	8·47
Number of days running ...	111	79
Daily average consumption..	15 tons 17 cwt.	18 tons 2 cwt.
Average speed	about 16½ knots	about 18½ knots

On referring to the above table, it will be seen that the figures of coal consumption per mile are satisfactory, and also the data prove a decided victory for the steam turbine over the reciprocating engines, insomuch as although the *King Edward* is by far the faster boat, her consumption of coal per mile is almost as low as that of the *Duchess of Hamilton*. In a previous issue we pointed out that one of the chief advantages gained by the adoption of the turbine was the possible modification in the "model" of the boat, as finer lines could be introduced for speed purposes. The *King Edward* in this respect also, we understand, has given entire satisfaction to her owners, and not unnaturally another boat of the same type, but 21 feet longer and with a speed of 21 knots, is being built, the Parsons Marine Steam Turbine Co. being at present engaged on the machinery.

It is also worthy of notice that the class of craft being built with turbine machinery at the present time comprise three high-speed yachts of large size, one being of the torpedo-boat type with water-tube boilers, so, as is pointed out, the turbines will have every opportunity of appearing at their best. The Parsons Company have also a torpedo-boat destroyer with a similar speed to the *Viper* (not being built to the order of the Admiralty) which we are informed will have a less consumption both in cruising and full speed than any other 30-knot boat in the Navy.

This vessel, which is named the *Velox*, was launched by her builders (hull and boilers), Messrs. R. W. Hawthorn, Leslie and Co., on the Tyne on February 11, and measures 210 ft. long, 21 ft. beam, with a moulded depth of 12 ft. 6 in., and to guard against "buckling" she has been specially "stayed" longitudinally. The *Velox*, to ensure economy at cruising speeds, has fitted in her a novel arrangement of power wherein engines of the ordinary reciprocating type are designed to work in conjunction with, and are coupled direct on to, the steam turbines, the turbines being kept in reserve for the higher speeds only. In considering coal consumption, it will be seen at once that the engine arrangement introduced by Mr. Parsons forms a very important item, because, as in the case of torpedo-boat destroyers, but a small percentage of their steaming is spent on full speed work; and also, as is well known, as all steam engines (steam

turbines included) do not work so economically when running much below the power for which they are designed. For the long periods on which these boats are simply cruising about, the coal consumed is only that of the two small triple compound reciprocating engines, the steam turbines not being utilised, thus reducing their "cruising" coal consumption to a minimum which, when running at full speed, is only increased by the low consumption derived from the use of the steam turbine.

The marine steam turbine, forming, as it does, "one of the most striking developments in the history of marine engineering," is largely adopted by private enterprise; but, as *Engineering* points out, "it is a little surprising that at present no vessel is in progress fitted with turbine machinery and built for the Royal Navy."

MECHANICAL VENTILATORS FOR MINES.[1]

THIS report is the outcome of a large number of experiments conducted under the directions of a strong committee of eminent mining engineers. Its object was to obtain exact information concerning the relative efficiencies of various ventilating fans. In order to make the comparisons of real value, the experiments were restricted to collieries provided with two fans, each of which could be used in turn; the conditions were therefore identical in each case. Only three kinds of fans were compared, viz., the Guibal, the Schiele and the Waddle, with the result that the Guibal decidedly carried off the palm. But, as pointed out in the report, the conclusions arrived at are not beyond criticism, because the efficiencies were determined in each case by taking the ratio between the so-called "useful effect in air" and the indicated horse-power of the steam-engine used for driving the fan, without knowing how much power was consumed in overcoming the inherent resistance of the engine. Some experiments made in Belgium in 1899 were more satisfactory, because this point was taken into consideration. Here it was found that the Rateau fan had a decidedly higher mechanical efficiency than the Guibal.

The Committee has adhered to Murgue's time-honoured method of comparing the resistance of any given mine to that of an orifice in a thin plate. No doubt the idea of an imaginary "equivalent orifice" has served a useful purpose, but a simpler and plainer way of expressing the amount of resistance is that advocated by Hanarte; he reckons the resistance of a mine by the horse-power required to overcome it, and there is much to be said in favour of his proposal to classify mines according to this system.

Long pages crowded with figures bear testimony to the pains taken by the Committee to fulfil its task, and it is interesting to find that its observations afford a verification of the two fundamental formulæ of centrifugal ventilators. Mr. Walton Brown, the indefatigable secretary of the Institution of Mining Engineers, may be fairly congratulated upon the useful report which he has drawn up.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The 233rd meeting of the Junior Scientific Club was held on February 21. Dr. Hedin, of the Jenner Institute of Preventive Medicine, read a paper, chiefly an account of his recent researches, on "The Proteolytic Enzymes of the Animal Body."

MR. T. P. KENT, scholar of Christ Church, Oxford, and assistant master at Cranleigh School, Surrey, has been appointed professor of mathematics at Rondebosch College, Cape Town.

IN view of the date appointed for the coronation of their Majesties, the day examinations of the Board of Education, South Kensington, arranged to be held during the week ending June 28, will be held during the week ending July 5.

AN article on the use of ordnance survey maps in teaching geography, contributed by Sir Archibald Geikie to the February number of the *Geographical Teacher*, directs attention to the invaluable aid to the study of geography which these maps afford. In spite of the fact that the maps are adapted to instruction in the most elementary or the most advanced stages of geography, and are so cheap, they are but rarely used, and the geographical lesson is usually conducted in the unintelligent way with which we are all familiar. Hung upon the wall of the schoolroom, the maps encourage the study of home geography in the pupils, and give them facility in map-reading. Attention may then be directed to the information the maps contain as to the configuration or topographical features of the land, the system of contouring, and the method of plotting profiles or sections across a piece of ground. The teacher can then pass to the intelligent consideration of the causes of the varying physical features of the land, using for this purpose the maps of the Geological Survey, or can derive lessons on the influence of physical features upon the history and progress of the inhabitants of a country. Many other similar uses can be made of the maps, and by adopting them geography may be made a scientific study instead of a jumble of words, figures and phrases. It is to be hoped that Sir Archibald Geikie's paper will be read by every teacher who desires to make the geography lesson a means of cultivating the intelligence. Another paper in the *Geographical Teacher* which will assist this object is by Mr. A. M. Davies, on the geography of Greater London. Mr. James Bryce's address on the importance of geography in education, delivered at the recent annual meeting of the Geographical Association and already noticed (p. 284), appears in the same number of the magazine.

A REPORT of the discussion on reform in the teaching of mathematics, which took place at the meeting of the Mathematical Association on January 18, is published in the *Mathematical Gazette*. Prof. A. Lodge opened the discussion with a paper in which he advocated the introduction of a course of geometry similar to that taken in French schools. The chief points in the French text-books which he desired to see introduced are:—(1) The more orderly arrangement of propositions; (2) the entire separation of theorems from problems of construction, hypothetical constructions being used in proving a theorem; (3) the closer association of a proposition and its converse when both are true; (4) the adoption of arithmetical notions and algebraic processes; (5) the early introduction of simple loci; (6) insistence on accurate figures drawn by accurate and practical processes; (7) practice in exercises from the very beginning. In the subsequent discussion, Prof. G. M. Minchin, F.R.S., gave instances of the failure of boys to understand Euclid's language and methods, and also described desirable reforms in the teaching and nomenclature of dynamics and hydrostatics. The discussion was, however, mainly concerned with the teaching of geometry, and the general opinion of the speakers was that demonstrative geometry should be preceded by a course of work with ruler, compasses and protractor, in which simple measurements and constructions formed the chief part. This has been done for many years in Scottish schools and also in some elementary schools in England. One speaker expressed his surprise at the amount of work that could be done with a pencil, ruler, a pair of scissors and a piece of paper, and others referred to the value of illustrations of geometrical truths obtained with similar materials. It seems, however, to have been overlooked that this work has long been part of kindergarten teaching.

SCIENTIFIC SERIAL.

American Journal of Science, February.—On geometric sequences of the coronas of cloudy condensation, and on the contrast of axial and coronal colours, by C. Barus.—On a new occurrence of sperrylite, by H. L. Wells and S. L. Penfield. A minute quantity of sperrylite, platinum arsenide, was found in a specimen of platiniferous copper ore from the Rambler Mine, Medicine Bow Mountains. Platinum is found in ores from all parts of the mine in quantities varying from ·06 to 1·4 ounces per ton.—A cosmic cycle, by F. W. Very.—Studies of Eocene mammalia in the Marsh collection, Peabody Museum, by J. L. Wortman. The present instalment deals chiefly with *Patriofelis ferox*, and contains a detailed criticism of the views recently expressed by H. F. Osborn.—On a miniature anemometer for stationary sound-waves, by B. Davis. By sufficiently reducing the dimensions of the cups and vanes in the ordinary anemometer, it was found possible to determine the relation between the amplitude of vibration and the rate of rotation in

[1] Report of the Committee of the North of England Institute of Mining and Mechanical Engineers, and the Midland Institute of Mining, Civil and Mechanical Engineers. By Mrs. M. Walton Brown. *Transactions of the Institution of Mining Engineers* (vol. xvii. pp. 96+xvii plates).

a stopped organ pipe giving its first overtone. The cups used varied in size from 7·5 mm. to 4·5 mm., and the lengths of the arms from 20 mm. to 8 mm. The curves found correspond closely to the sine curves near the middle of the loop where the amplitudes of vibration have considerable magnitude.—The occurrence of fossil remains of mammals in the interior of the states of Pernambuco and Alagoas, Brazil, by J. C. Branner.—The estimation of copper as cuprous sulphocyanide in the presence of tin, antimony, arsenic and bismuth, by R. G. van Name. The accurate estimation of copper in the presence of the above-named metals was found to be practicable provided that certain precautions were taken as to the amount of free acid, ammonium bisulphite and sulphocyanide used.—The composition of yttrialite, with a criticism of the formula assigned to thalenite, by W. F. Hillebrand. The empirical formula of Hidden and Mackintosh for yttrialite is confirmed. The formula proposed by Benedicks for thalenite is to be regarded as doubtful.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Astronomical Society, February 14.—Anniversary Meeting.—Dr. J. W. L. Glaisher, F.R.S., president, in the chair.—The secretaries read the annual report of the council, containing obituary notices of deceased fellows and associates, reports of the work of observatories in Great Britain and Ireland and the Colonies, and notes on the progress of astronomy during the past year.—The president announced that the council had awarded the Society's gold medal to Prof. J. C. Kapteyn, of Groningen, Holland, for his work in connection with the Cape Photographic Durchmusterung and his researches on stellar distribution and parallax. The president delivered an address, setting forth the grounds upon which the award had been made. The address dealt chiefly with Prof. Kapteyn's great work in measuring and reducing the stellar photographs taken at the Royal Observatory, Cape of Good Hope, and in preparing the catalogue, which had been completed and published, forming three volumes of the *Annals* of the Cape Observatory. The actual photographing of the plates was begun by Dr. (now Sir David) Gill in 1886 and finished in 1890. Prof. Kapteyn spontaneously undertook the great work of measurement and reduction and the formation of the catalogue—a labour which occupied him more than twelve years. The catalogue contained 454,875 stars down to about the 9·5 magnitude, from − 18° to the South Pole.—The president presented the gold medal to Prof. Kapteyn.—He also presented the Jackson-Gwilt bronze medal to the Rev. Thos. D. Anderson, for his discoveries of Nova Aurigæ and Nova Persei.

Entomological Society, February 5.—The Rev. Canon Fowler, president, in the chair.—The president announced the appointment of Mr. F. D. Godman, F.R.S., Prof. E. B. Poulton, F.R.S., and Dr. D. Sharp, F.R.S., as vice-presidents for the session.—Prof. Poulton exhibited with lantern a series of slides belonging to Prof. Meldola, made from actual specimens by the three-colour process, illustrative of mimicry in British and exotic Lepidoptera and Hymenoptera. He also exhibited the several specimens from which the lantern slides had been prepared.—Mr. C. G. Barrett exhibited a series of the perfect insect of *Glottula fusca*, Hpsn., together with ears of maize (locally called mealies), showing the damage done by the well-grown larva of the species, which lives in the first place in the stem, eating the pith from the ground, and afterwards attacking the cobs, and eating from the inside into the bases of the unripe grains, which then change colour and shrivel up. He also exhibited specimens and figures to illustrate the life histories of South African Heterocera, received from Miss Frances Barrett, Buntingville, Transkei, South Africa.—Mr. W. L. Distant exhibited two specimens of Coleoptera which he received alive from the Transvaal—one *Anthia thoracica*, Thunb., now dead, the other *Brachycerus granosus*, Gyll., still living. These insects had been sent him by Mr. Robert Service, of Dumfries, who received them from Sergt. Peter Dunn, of the volunteer company of the Scottish Borderers. The genus Anthia extends to the southern Palæarctic region, and there seems little doubt that these species could be easily acclimatised there. All they require at home is the run of a good palm or orchid house.—Mr. R. Adkin exhibited a series of *Acidalia aversata*. The parent moth (a banded female, the male parent not being known) was taken at Lewisham in June, 1900. Of the resulting larvæ, about one-half fed-up rapidly and produced imagines in the autumn of the same year—a very unusual circumstance; the remainder hibernated and produced imagines in June of the following year, thus occupying the normal time in completing their metamorphoses. The proportion of individuals following the female parent in the two portions of the brood was almost equal.—Mr. G. C. Champion exhibited long series of *Leptura stragulata*, Germ., and *Strangalia pubescens*, Fabr., from the pine-forests of Aragon and Castile, showing the great variation in colour of the two species in these districts, whereas the allied forms occurring in the same places, viz. *L. rubra*, Linn., *L. distigma*, Charp., *L. unipunctata*, Fabr. and *L. sanguinolenta*, Linn., were perfectly constant; also *Dermestes aurichalceus*, Küst., which he and Dr. Chapman had found everywhere in abundance in the old nests of the processionary-moth (*Cnethocampa processionea*, Linn.) on the pines in these forests.—Dr. T. A. Chapman exhibited in illustration of his paper, on a new subfamily of Pyralidæ, living larvæ of *Hypotia corticalis*, Schiff, as well as preserved larvæ, pupa-cases, imagines, and prepared wings to show the neuration of that species.—Mr. Edward Meyrick communicated descriptions of new Australasian Lepidoptera.—Mr. W. F. Kirby communicated a Report on a collection of African Locustidæ, chiefly from the Transvaal, made by Mr. W. L. Distant.

Geological Society, February 5.—Mr. J. J. H. Teall, V.P.R.S., president, in the chair.—The matrix of the Suffolk Chalky Boulder-Clay, by the Rev. Edwin Hill. The author has been examining with the microscope washed residues from Boulder-Clays. He is able to group together the specimens from localities along a belt of country from Lowestoft to Bury St. Edmunds, as containing granules of Secondary clays and limestones. Other specimens contain granules which may be the same kind decomposed, others granules of other kinds; all these lie outside the belt occupied by the group, though some are very near it. The results lead to the conclusion that the materials of the matrix in the Suffolk Chalky Boulder-Clay were not brought from the east or north, but from inland, and not from so far inland as the Coalfields. Their sources therefore lie on a limited belt, bordering the Boulder-Clay area.—On the relation of certain breccias to the physical geography of their age, by Prof. T. G. Bonney, F.R.S. The author has endeavoured in this paper to collect from published accounts and his own observations the evidence which certain well-known and important beds of breccia afford as to the physical conditions prevalent when they were formed. Reasons are given for concluding that the Rothliegende (and probably the Triassic) breccias are indicative of a continental climate, due to a great extension of land or more probably the existence of a mountain-region on the west—winters with severe cold and snow, but rather hot and arid summers. The Caithness breccias are perhaps more analogous to the stone-rivers of the Falkland Islands, but they also indicate a rather low temperature; while the Flysch-breccias land us in the following dilemma, namely, that either similar temperatures existed in Switzerland, and that there was also an important highland district, of which no remnant can be found, within a short distance of the breccia-beds, or they must be the product of a range not inferior to the present Alps, which also has completely disappeared, and would be (for reasons given) very difficult to locate. But, even in the latter case, it must be admitted that a temperature if not lower, at any rate not higher than the present, prevailed in central Europe late in the Eocene period.

Zoological Society, February 4.—Prof. G. B. Howes, F.R.S., vice-president, in the chair.—Dr. Chalmers Mitchell read, on behalf of Mr. E. Degen, a paper entitled "Ecdysis, as Morphological Evidence of the original Tetradactyle Feathering of the Bird's Fore-limb, based specially on the Perennial Moult of *Gymnorhina tibicen*." The material on which the paper was based consisted of a large series of specimens of the Gymnorhina obtained at regular intervals throughout the moulting-period, and the author had thus been able to give a very complete account of the perennial replacement of the feathers, avoiding the errors due to observations on the altered habits as produced by captivity. The author showed that the moulting of the wing-feathers took place in definite groups, and indicated a composite origin of the modern feathering.—A communication from Prof. W. Blaxland Benham contained some notes on the osteology of

the short-nosed sperm-whale (*Cogia breviceps*), based on an examination of a specimen which had been washed ashore on the coast of Otago, New Zealand. The soft parts of the same specimen had formed the subject of a paper presented to the Society by the same author in May of last year.—Two additional papers on the results of the "Skeat Expedition" to the Malay Peninsula were read. The first, by Mr. F. F. Laidlaw, gave an account of the dragon-flies (with the exception of Agrioninæ) collected, and a list of all other species that had previously been known from the Peninsula. One new genus, Climacobasis, and twelve new species were described. The second paper, by Mr. W. E. Collinge, contained an account of the collection of non-operculate land and fresh-water mollusca made by the expedition, and included descriptions of three new genera (Apoparmarion, Paraparmarion and Cryptosemelus) and eight new species, besides contributions to the anatomy of certain species. Descriptions of three species of Prisma in the British Museum collection, one of which, *P. smithi*, was new, were also included in the paper.—A communication from Mr. W. F. Kirby contained a list of twenty-three species of Orthoptera, of which specimens were contained in a collection made by Sir Harry Johnston, K.C.B., in the Uganda Protectorate.

Mathematical Society, February 14.—Dr. E. W. Hobson, F.R.S., president, in the chair.—Prof. Lamb read a paper on Boussinesq's problem. The problem is to determine the strain produced at any point of a semi-infinite elastic solid, with a plane boundary, by the application of pressure to its surface; the solution is obtained in a straightforward manner by the use of Bessel's functions.—Mr. A. Young read a paper on quantitative substitutional analysis. This paper is a continuation of a previous one, published in *Proceedings*, vol. xxxiii., in which the conditions that a function of several variables may be unaltered by particular substitutions, belonging to particular groups, were applied to the development of relations between the concomitants of quantics.—Prof. Love explained a new proof of a well-known theorem concerning zonal harmonics.—The following papers were communicated by the president:—Dr. H. F. Baker, elementary proof of a theorem for functions of several variables. The theorem is that, if an ordinary power series in any number of variables does not vanish for zero values of the variables, the inverse of the series can be expanded in a converging series; it is proved also that the range of convergence of the new series is the same as that of the original series, provided that no zero of the latter is contained in this range.—Mr. T. J. I'A. Bromwich, note on the wave surface of a dynamical medium æolotropic in all respects. The kinetic energy of the medium is taken to be a homogeneous quadratic function of the component velocities, and the potential energy is taken to be a similar function of the components of strain and rotation; the equations of motion are deduced from the Hamiltonian principle, and the form of the general wave surface is obtained without having recourse to the methods of vector-analysis.—Prof. A. C. Dixon, on plane cubics. This note contains some further developments of the theory of corresponding points on a cubic, as given by Salmon, and the closely connected theory of three conics.—Mr. W. H. Young, (1) on the density of linear sets of points, (2) on closed sets of points defined as the limit of a sequence of sets of points. The first paper deals with the distinction between sets of points which are everywhere dense and sets which have the property that every point is a limiting point on both sides; the distinction is of great importance in the application of the theory of sets of points to questions concerning functions of real variables; illustrative examples are given. The second paper deals with the geometrical connection between a set of given rank, in a countably infinite number of closed sets, and the corresponding limiting set; the relation between the content of each set of the countably infinite number and the content of the limiting set is discussed in detail.

Royal Meteorological Society, February 19.—Mr. W. H. Dines, president, in the chair.—Mr. E. Mawley submitted his report on the phenological observations for the year 1901. He showed that as affecting vegetation the weather was chiefly remarkable for the scanty rainfall during the growing period of the year. The deficiency was not confined to any part of the British Isles, but was more keenly felt in the English counties than in either Scotland or Ireland. Wild plants came into flower very late, but not quite as late as in the previous phenological year, which was an exceptionally backward one. The swallow, cuckoo and other spring migrants were, as a rule, rather behind their usual dates in reaching these islands. The crops of wheat, barley and oats were all more or less above average in Scotland and Ireland. On the other hand, in England, although there was a fair yield of wheat, that of barley and oats was very deficient. Hay proved everywhere a small crop, and especially so in the southern districts of England. Beans, peas, turnips, swedes, mangolds and potatoes were all more or less under average in England, but either good or fairly good elsewhere. The yield of hops proved singularly abundant. Apples, pears and plums were below average, especially apples, but the small fruits, as a rule, yielded well. Taking farm and garden crops together, seldom has there been a less bountiful year.

MANCHESTER.

Literary and Philosophical Society, February 4.—Mr. Charles Bailey, president, in the chair.—Mr. J. E. King read the first part of a paper on folklore of the North American Indians, from the Jesuit relations (1611 to 1637). Without attempting to give any complete account of Indian culture, the paper described and illustrated particular practices observed by the Jesuits. The savages believed in two main sources of disease, viz., desires in the mind of the patient, or evil practices of an enemy working by witchcraft. The sorcerers, or medicine men, claimed to cure disease and also to produce it, when desired, by practices which come under the head of sympathetic magic. Great importance was attached by the Indians to dreams, singing, dancing and feasting. Wherever these practices had a magical meaning, they were forbidden by the Jesuits to their converts.—The animistic theory of nature is illustrated by the observances with regard to the bones of animals eaten at feasts, the treatment of fishing nets, and offerings to dangerous rocks and rapids. The life of the human soul after death was a shadow of the life on earth. The ghost of the dead was driven from the abode of the living, and the name of the dead was not to be mentioned.—Mr. W. E. Hoyle exhibited two carved wooden bowls from British Columbia, and referred to the skill shown by the Indians in retaining in their carvings the special characteristics of the various animals represented, illustrating his remarks by a series of lantern slides.—Mr. Francis Nicholson drew attention to a paragraph in Mr. Elijah Helm's "Chapters in the History of the Manchester Chamber of Commerce," wherein it is stated that as early as the first half of the seventeenth century cotton was brought from Cyprus and Smyrna to London and thence to Lancashire, where it was spun by hand on the single spindle frame. Mr. Nicholson pointed out that most of the cotton used in Lancashire at that time probably came from the West Indies, and, as confirming this, he read a letter written from London by his great-grandfather, Robert Nicholson, to his brother, James, in Liverpool in 1749, where he quotes: "Jamaica cotton is sold at 16*d.* per lb., some of the very choicest 16½*d.* per lb., Leeward Islands 14*d.* per lb."

CAMBRIDGE.

Philosophical Society, February 3.—Prof. Macalister, president, in the chair.—Oxidation in presence of iron, by Mr. H. J. H. Fenton. The remarkable influence which is exerted by traces of iron in determining and regulating the oxidation of various organic substances was first observed by the author about twenty years ago, and the observation has since opened up a very wide and fruitful field for investigation. The work is still being extended in several directions, and in the present communication a brief summary is given of the principal researches on the subject already published, and of new results which have recently been obtained. The conditions of this oxidation-method show some very close analogies with certain natural processes, and many experiments are in progress with a view of throwing further light upon the function of the iron.—Decomposition of hydrogen peroxide by light, by Mr. R. F. D'Arcy. The author gave an account of experiments showing:—(*a*) That dilute solutions of hydrogen peroxide are rapidly affected by exposure to sunshine. Experiments were chiefly made with aqueous solutions containing 4 per cent. of "20 vol." H_2O_2. Exposure of such a solution in a flask to the sunshine of five days in June resulted in the decomposition of about three-quarters of the hydrogen peroxide. In open dishes it is more rapidly decomposed, and the effect in this case is not dependent, at any rate to any considerable extent, on the evaporation taking place simultaneously. The effect is not a temperature effect. This property of hydrogen peroxide may possibly be of some importance in some of its reactions. (*b*)

That the surface of a solution of hydrogen peroxide undergoing this decomposition is capable of discharging negative electrification. (*c*) That days on which sunlight decomposes hydrogen peroxide most rapidly are the days on which the discharging action is most pronounced. The author draws from these experiments the conclusion that the decomposition of hydrogen peroxide by light is a possible source of production of positive and negative ions in the atmosphere. A detailed account is to be found in the *Phil. Mag.*, January.—Note on a method for determining the concentration of hydrogen ions in solution, by Mr. H. O. Jones and Mr. O. W. Richardson. The investigation described was suggested by a series of observations by Mr. Fenton and one of the authors. They showed that oxal-acetic hydrazone decomposed in presence of water at 100° C. into pyruvic hydrazone and carbon dioxide; but that in the presence of hydrogen ions in sufficient concentration the products were pyrazolone carboxylic acid and water. It was suggested that these reactions might be explained by supposing that the negative ion lost carbon dioxide on heating; whereas the undissociated molecule lost water. Hence the presence of hydrogen ions by diminishing the concentration of the negative ion would diminish the amount of carbon dioxide produced. The experiments here described were undertaken with the view of testing quantitatively the validity of the above hypothesis and the value of the method for determining the concentration of the hydrogen ions in a solution. The authors find that, in the case where the ionisation due to the hydrazone itself is negligible compared with that of the acid used, the experimental results agree with the theoretical conclusions.—The formation of dinitrophenoxazines, by Mr. J. C. Crocker.—When picryl chloride reacts with orthoxyamido-compounds in the presence of alkali, hydrochloric acid and nitrous acid are eliminated, and condensation takes place to a dinitrophenoxazine. Eikonogen, for instance, gave naphthodinitrophenoxazine sodium sulphonate, which consists of minute bronze plates soluble in water.—The interaction of thiocyanates, picryl chloride and alcohols, by Mr. J. C. Crocker. When picryl chloride acts on thiocyanate in absolute alcohol solution, a yellow crystalline body is obtained. It melts at 138°, contains an ethoxy-group, two picryl groups and a sulphur atom. On hydrolysis it gives picramide. Hydrochloric acid is set free in the reaction.—Oxidation of glucosone to trioxybutyric acid, by Mr. R. S. Morrell. Glucosone, prepared from glucose by the action of hydrogen peroxide in the presence of ferrous sulphate, on oxidation with bromine in aqueous solution yielded trioxybutyric acid. The identity of the trioxybutyric acid was established by comparing its calcium and lead salts with those obtained from the trioxybutyric acid which is formed when erythrite is oxidised by nitric acid, also by the reduction of the calcium salt by hydriodic acid and phosphorus to normal butyric acid.—Note on the reduction of a ternary quantic to a symmetrical determinant, by Dr. A. C. Dixon.

Edinburgh.

Royal Society, January 20.—Lord Kelvin in the chair.—Lord Kelvin, in a paper on the specification of stress and strain in the mathematical theory of elasticity, showed how a perfectly symmetrical system applicable to all kinds of strains and not merely to very small strains could be developed by considering the elongations of the edges of a tetrahedron and the related stresses (see *Phil. Mag.* for January, 1902). The method for bringing this system into relation with the ordinary system for infinitesimal strains was indicated, and the discussion was greatly facilitated by the use of models.—Dr. W. Brodie Brodie read a paper on the condition of the iron in the spleen, and detailed some of the results of an investigation into the histological and chemical position of the iron in this organ. By the use of microchemical methods, the metal was found contained in cells and also in bodies not of a cellular nature. Three varieties of iron-containing elements were described as belonging to the latter class. Three proteid bodies containing iron which had been obtained by means of purely chemical methods were also described.—Lord Kelvin communicated a paper on the molecular dynamics of a crystal, discussing in particular (*a*) stable and unstable homogeneous assemblages, (*b*) deviation from homogeneousness in surface layers, (*c*) tensile strength, (*d*) cleavage. The whole discussion was based upon the Boscovich view that the action between neighbouring atoms is attractive or repulsive according to their distance apart. The forces acting upon a given atom will depend, not only upon the nearest neighbours, but also upon those at greater distances. Taking simple configurations, Lord Kelvin showed how during the condensation of an assemblage of atoms configurations of instability might arise, and how the group originally monatomic might either assume a new stable configuration of different density or break up into a diatomic configuration of greater stability. By a process of successive approximations, the final positions of the end particles of a one-dimensional row of particles acting on one another, according to an assumed Boscovichian law, were calculated. Reckoning from the end, the distances between the successive pairs of contiguous particles were alternately greater and less than the ultimately constant distance to which they converged as we passed further and further from the end. After the first nine or ten particles, the arrangement became uniform.—A communication by Dr. Thomas Muir, on the theory of Jacobians in the historical order of development up to 1841, was also received.

Paris.

Academy of Sciences, February 17.—M. Bouquet de la Grye in the chair.—A study of the conditions to be realised in the execution of negatives in order to obtain homogeneity and the maximum of exactitude in the determination of the coordinates of stellar images. Formulæ for evaluating the influence of the whole of the causes of error which affect the results, by M. Lœwy. The rectilinear coordinates of photographic stellar images are liable to two distinct classes of errors, the first being due to the unequal sensibility of the gelatine layer and to the irregular deformations which it undergoes during development, and the second having its origin in the subsequent measuring operations. A careful analysis of the relative magnitudes of these two causes of error in the case of stars of different orders of magnitude is given and a formula worked out for the probable error, from which it is hoped that a still higher accuracy may yet be obtained by the photographic method.—An apparatus for measuring differences of longitude with the aid of photography, by M. G. Lippmann. The essential part of the apparatus consists of a transparent mirror inclined at an angle to a mercury bath, and has already been described as a means of measuring photographically small zenithal distances. It is equally applicable to the measurement of small differences of longitude.—The action of potassium hydride on ethyl iodide and methyl chloride New methods of preparation of ethane and methane, by M. Henri Moissan. Potassium hydride heated in a sealed tube with ethyl iodide at about 200° forms ethane and potassium hydride. The reaction is not complete, but is perfectly free from bye-products. The ethane is separated from the hydrogen by means of liquid air, and from the ethyl iodide in excess by fractional distillation and subsequent washing with alcohol and water. The gas was proved by analysis to be perfectly pure. The reaction with methyl chloride is analogous, pure methane being produced.—Study of the vineyards of high yield in central France, by M. A. Müntz. It is shown to be more advantageous to moderate production in order to obtain a superior wine than to exaggerate the yield by methods giving enormous quantities of wine of feeble quality.—The estimation of sugars in the blood, by MM. R. Lépine and Boulud. A comparison of the polarimetric and copper reduction methods.—The mechanical action of gelatine on solid substances and particularly on glass, by M. L. Cailletet. Gelatine on drying exercises a very energetic mechanical action on the surfaces to which it adheres. On surfaces of glass, polished marble, Iceland spar and fluorspar, pieces are broken off, and a cylindrical tube of thin glass may be broken by means of the action of a small quantity of drying glue.—M. Charles André was elected a correspondant for the section of astronomy in the place of the late Dr. Gould.—Perturbations of the major axis of small planets, by M. Jean Mascart.—On quasi-entire functions, by M. Edmond Maillet.—On a class of partial differential equations integrable by successive approximations, by M. R. d'Adhémar.—On some transformations of contact, by M. W. de Tannenberg.—On a form of electric thermometer, by M. Georges Meslin. In certain cases the rapidity with which thermocouples follow the temperature changes of the medium in which they are placed is disadvantageous. The author therefore proposes to use the variation of electromotive force of a Latimer Clark cell with temperature as a thermometer, the thermal lag of which is very pronounced compared with a thermocouple.—Researches on ionised gases, by M. P. Langevin. A development of the theory of ionised gases of J. J. Thomson, together with an experimental confirmation of the theoretical deductions.—On the transparency of liquid conductors for the

Hertzian oscillations, by M. Charles Nordmann. The transparencies for the waves vary in the same sense as their resistances, increasing less rapidly than a direct proportion, but more rapidly than in proportion to their square roots.—The conductivity of liquid dielectrics under the influence of the radium and Röntgen rays, by M. P. Curie. Under the action of the radium rays there is a marked increase of electrical conductivity in liquid dielectrics, and on replacing the radium rays with the Röntgen rays, effects of a similar order are observed. The magnitude of the increase of conductivity observed under the action of the rays varies greatly with the liquid used, from 20×10^{-14} mhos per c.c. in the case of carbon bisulphide to $1 \cdot 3 \times 10^{-14}$ mhos per c.c. for liquid air.—Molecular fields of force, by M. S. Leduc.—A second quarter of meteorological observations at Quito, by M. F. Gonnessiat.—On praseodidymium chloride, by M. Camille Matignon. The anhydrous chloride can be obtained from the crystallised $PrCl_3,7H_2O$ by heating in a current of hydrogen chloride at 185° C. Thermochemical data are given for the heats of solution of the various hydrated chlorides.—On the diapedesis of leucocytes charged with lecithin, and on the absorption of the lecithin by the vascular endothelium, by MM. H. Stassano and F. Billon.—Comparison of the egg-laying capacity of fowls fed on meat and on grain, by M. Frédéric Houssay. It was found that on a meat diet there was a marked increase both in the number of eggs produced and also in the average weight of the egg obtained.—On the evolution of stolonial formations in Syllidians, by M. G. Pruvot.—On two caoutchouc-bearing plants of Indo-China, by M. Gustave Quintaret.—On the origin and the differentiation of the vascular meristem of the petiole, by M. Bouygues.—New observations on the *Tanghin du Ménabé* (*Menabea venenata*) and on its toxic and medicinal root, by M. Edouard Heckel.—On the properties of the reflection fringes of silvered plates, by M. Maurice Hsmy.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 27.

ROYAL SOCIETY, at 4.30.—Note on the Discovery of a New Trypanosoma: Lieut.-Colonel David Bruce, R.A.M.C., F.R.S.—The Bakerian Lecture will be delivered by Lord Rayleigh, F.R.S., on the Law of the Pressure of Gases.
SOCIETY OF ARTS at 4.30.—The Industrial Development of India: Nilkanth B. Wagle.
INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Electric Shock and Legislation thereon: Major-General C. E. Webber, C.B., R.E.—Electric Shocks: F. B. Aspinall.—Electric Shocks at 500 volts (illustrated by a Demonstration of 500 volts): A. P. Trotter.

FRIDAY, FEBRUARY 28.

ROYAL INSTITUTION, at 9.—Gold Mining in Klondyke: Prof. H. A Miers, F.R.S.
PHYSICAL SOCIETY, at 5.—(1) On Focal Lines and Anchor-ring Wavefronts: (2) Contributions to the Theory of the Resolving Power of Objectives: Prof. J. D. Everett, F.R.S.—The Absorption, Dispersion, and Surface-colour of Selenium: Prof. R. W. Wood.
INSTITUTION OF CIVIL ENGINEERS, at 8.—Indicating High-Speed Steam-Engines: A. M. Arter.

SATURDAY, MARCH 1.

ROYAL INSTITUTION, at 3.—Some Electrical Developments: Lord Rayleigh, F.R.S.

MONDAY, MARCH 3.

SOCIETY OF ARTS, at 8.—Photography applied to Illustration and Printing J. D. Geddes.
VICTORIA INSTITUTE. at 4.30.—The Physical History of the New Zealand Fjords: J. Malcolm Maclaren.

TUESDAY, MARCH 4.

ROYAL INSTITUTION, at 3.—The Temperature of the Atmosphere: its Changes and their Causes: W. N. Shaw, F.R.S.
SOCIETY OF ARTS, at 8.—Structural Colour Decoration of the Interior of Public Buildings: G. C. Horsley.
ZOOLOGICAL SOCIETY, at 8.30.—Exhibition of Photographs of Animal-life in the Egyptian Soudan: E. N. Buxton.—On the Origin of Pearls: Dr. H. Lyster Jameson.—On the Organ of Jacobson in the Elephant-Shrew (Macroscelides): Dr. R. Broom.
INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed*: Electrical Traction on Railways: W. M. Mordey and B. M. Jenkin.

WEDNESDAY, MARCH 5.

SOCIETY OF ARTS, at 8.—Sound Signals: E. Price Edwards.
ENTOMOLOGICAL SOCIETY, at 8.—On Mr. Guy A. K. Marshall's Five Years' Experiments and Observations in Mimicry and Warning Colours in South African Insects: Prof. Edward B. Poulton, F.R.S., with an Appendix by W. L. Distant and Colonel C. T. Bingham.—Notes on some Cases of Sexual Dimorphism in Butterflies; with an Account of Experiments made by Mr. Guy A. K. Marshall: Dr. Frederick A. Dixey.—A Monograph of the Genus Acrida, with Notes of some Allied Genera, and Descriptions of New Species: Malcolm Burr.—(*a*) Notes on Hawaian Wasps, with Descriptions of New Species; (*b*) Four New Species and a New Genus of Parasitic Hymenoptera (Ichneumonidæ) from the Hawaian Islands; (*c*) On the Generic Characters of Hawaian Crabronidæ; Four New Genera Characterised: R. C. L. Perkins.
SOCIETY OF PUBLIC ANALYSTS, at 8.

THURSDAY, MARCH 6.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: On the Spark Discharge from Metallic Poles in Water: Sir Norman Lockyer, F.R.S.—Experimental Researches on Drawn Steel. Part I. The Influence of Changes of Temperature on Magnetism. Part II. Resistivity, Elasticity and Density, and the Temperature Coefficients of Resistivity and Elasticity: J. R. Ashworth.—On the Effects of Magnetisation on the Electric Conductivity of Iron and Nickel: G. Barlow.—The Differential Equations of Fresnel's Polarisation-vector, with an Extension to the Case of Active Media: J. Walker.
LINNEAN SOCIETY, at 8.—On some New Species of Lepadidæ in the British Museum (Nat. Hist.): Prof. A. Gruvel.—On the Morphology of the Brain in the Mammalia, with Special Reference to the Lemurs, Recent and Extinct: Dr. G. Elliot Smith.
RÖNTGEN SOCIETY, at 8.30.—Localisation; with Demonstration of a Simple Direct Reading Apparatus: Dr. Barry Blacker.
CHEMICAL SOCIETY, at 8.—The Slow Oxidation of Methane at Low Temperatures: W. A. Bone and R. V. Wheeler.—Isomeric Additive Compounds of Dibenzyl Ketone and Deoxybenzoin with Benzal-*p*-toluidine, *m*-Nitrobenzalaniline and Benzal-*m*-nitraniline, Part III.; F. E. Francis.—Mesoxalic Semi-Aldehyde: H. J. H. Fenton and J. H. Ryffel.—*m*-Nitrobenzoylcamphor: M. O. Forster and F. M. G. Micklethwait.—Picrimidothiocarbonic Esters: J. C. Crocker.

FRIDAY, MARCH 7.

ROYAL INSTITUTION, at 9.—Radio-active Bodies: Prof. H. Becquerel.
GEOLOGISTS' ASSOCIATION, at 8.—The Zones of the White Chalk of the English Coast. III. Devonshire: Dr. A. W. Rowe.

SATURDAY, MARCH 8.

ROYAL INSTITUTION, at 3.—Some Electrical Developments: Lord Rayleigh, F.R.S.

THURSDAY, MARCH 6, 1902.

THE VOYAGE OF THE "VALDIVIA."

Aus den Tiefen des Weltmeeres, Schilderungen von der deutschen Tiefsee-expedition. Von Carl Chun. (Jena: Gustav Fischer, 1900.) Lief. i.–xii. Price 18 mk.

ON the return of the German deep-sea expedition, it was decided to issue a popular account of the voyage and its results. Naturally this task fell to the leader, and in the volume before us Prof. Chun acquits himself of it.

The work opens with a short review of the history of deep-sea exploration, from the discovery by Sir John Ross in the year 1818 of living brittle-stars in 1000 fathoms of water to the outfitting of the German expedition in 1898—pages which will be read in this country with a justifiable pride indeed, but also with the conviction that exertion is needed if we are still to hold our own in scientific exploration. In enumerating the problems which yet remain to be solved, and for the discussion of which his expedition was to furnish material, Prof. Chun mentions the bionomics and embryology of deep-sea animals, the distribution equatorwards of polar organisms, and bipolarity, but he does not here refer to a question of considerable interest which has been greatly enlightened by the *Valdivia's* researches, the vertical distribution of the mesoplankton, which has been found, by the German expedition and by Dr. G. H. Fowler independently at almost the same time, practically to cease at about 1000 fathoms—a result which agrees neither with the view previously held in some quarters that pelagic life extended throughout the depth of the ocean, nor with the opposite opinion that it did not exist below two or three hundred fathoms.

The route of the cruise was determined by the decision to explore, as far as possible, portions of the ocean the deep-water fauna of which was as yet imperfectly known. Two of the most important of these being the South Atlantic and a great part of the Indian Ocean, the course decided upon was one which, passing through the Faroe Channel and thence southwards to the Canaries, followed roughly the western coast of Africa to the Cape, then struck south-west to Bouvet Island and south-east from Bouvet Island to the neighbourhood of Enderby Land, traversed the length of the Indian Ocean to the Nicobars, passing Kerguelen, New Amsterdam and Sumatra on the way, crossed from the Nicobars by Ceylon, the Maldives, the Chagos and the Seychelles to Dar-es-Salaam, and finally led back along the east coast of Africa, through the Red Sea and Suez Canal, to the Mediterranean and so home. Besides Prof. Chun, the expedition comprised ten scientific members, a photographer and a conservator. The vessel chosen was the *Valdivia*, a Hamburg to West Indies liner of 2176 tons register, and considerable alterations were made to fit her for the voyage, among others the fitting up of a large ice-room, which was found very useful in enabling deep-sea animals to be examined alive by being kept at a low temperature. The scientific equipment was very elaborate, and certain practical details are worth noting. Indiarubber accumulators, used to take the weight of the nets and their wire, were perished by the heat of the tropics, though fortunately others of steel spring were at hand. The "Blake" dredge proved less serviceable than a trawl, its iron frame cutting too deep into the ooze. The bucket of the vertical net was of glass and without filtering surfaces, whereby a smaller quantity of plankton was gotten, but in better condition. No doubt the quantitative net, built on Hensen's pattern, which was carried was provided with a porous bucket. Both Negretti and Zambra's upsetting thermometer and one of the Siemens electrical type proved useful, but the latter is said to need further improvements.

The history of the voyage is sketched in a series of chapters. These are written in a light and popular vein, and are beautifully illustrated by photographs of places and natives, but only a few points in them call for notice here. The important observations began when the Canaries had been passed. In the Guinea Stream, the low specific gravity of the water was found to be connected with a peculiarity of the plankton, the spines and other processes of which are longer than those of the forms found in the north and south equatorial streams. Dredging here gave poor results, but the deep-sea plankton is very rich. In lat. 25° 26′ S. was discovered, in 936 fathoms, a new bank, believed to form part of a ridge (the "Walfish ridge"), which parts the colder southern waters from the tropics, much as the Iceland ridge fends off the Arctic waters. The fauna of this bank is very rich. Careful dredgings were also made on the Agulhas bank, from which valuable results may be expected. There appears to be here an intermingling of Atlantic and Indian forms with typical Antarctic species, and Prof. Chun suggests that the latter are relics of a time when these waters were colder than at present.

One of the most important results of the expedition was the rediscovery of Bouvet Island in lat. 54° 26′ S. and long. 3° 24′ E. The *Valdivia* was only able to establish the existence of a single volcanic island some five miles by four, covered with an immense glacier, but the possibility is not excluded that a second may exist, corresponding to Norris's "Thompson Island." The search for this island in stormy weather amid mist and icebergs seems to have been a fine piece of work. Dredgings in the neighbourhood revealed a very rich fauna, intermediate between that of the Magellan region and that of Kerguelen, but with many new forms. Bouvet Island appears to be near the point of a tongue of cold water which extends northwards from the Antarctic region. On leaving it, the *Valdivia* coasted along the edge of the drift-ice which marks this tongue, in a south-easterly direction, till she was confronted with the edge of the pack-ice in the neighbourhood of Enderby Land. During the whole of this course, the water was of great depth, varying from 2000 to 3000 fathoms. The temperature curve was also very interesting. Owing to the presence of ice, the surface water is considerably cooler than that of intermediate depths, the actually coldest layer (about $-1^{\circ}{\cdot}5$ C.) being at 30–40 fathoms. Below this the temperature rises, till at 300–400 fathoms it is $1^{\circ}{\cdot}7$ C. Then it falls gradually and, at the bottom, is $-{\cdot}5^{\circ}$ C. Naturally, a number of icebergs were met with in this region, mostly of table form well known in the Antarctic and often of immense size. After a number of pages

devoted to an account of the origin and destruction of these bergs, Prof. Chun passes to a consideration of the Antarctic plankton. The *Valdivia's* researches were made at the height of the summer, when the surface fauna and flora were at their richest. In many respects they resemble those of the Arctic region, the most striking difference being the complete absence of Ceratium and the rarity of other dinoflagellates, the place of which was taken by immense numbers of diatoms, especially those of the genus Chætoceras. The greatest richness of the plankton was reached at 20–40 fathoms, the poverty of the surface waters being probably due to their lower specific gravity owing to the presence of melting ice. A twilight flora (Schattenflora), such as is found in the lower layers of the surface waters in tropical seas, is wanting in the Antarctic. On December 17, the ship was brought to a stand by the pack-ice some hundred miles north of Enderby Land in 2300 fathoms, and bore away north-west to Kerguelen. A dredging taken shortly after this showed a rather rich fauna and brought up a glacier-borne boulder of red sandstone, proving that Enderby Land is not of purely volcanic origin.

The voyage northwards across the Indian Ocean, which was saddened by the death of Dr. Bachmann, the physician and bacteriologist of the expedition, does not appear to have produced any very startling results. After leaving Padang in Sumatra, researches were made on the deep basin (some 1000 fathoms) between Sumatra and the Mentawi Islands. This basin is separated from the open ocean by a ridge of only 400 fathoms, on which the group is situated, and the bottom temperature is therefore higher (5°·9 C.) than that outside the islands. At the same time there is a very rich surface flora. Consequently the bottom fauna is extraordinarily rich. In this neighbourhood a specimen of Spirula was taken in perfect condition. A short visit to Suvadiva Atoll in the Maldives gives the author an opportunity for some remarks on that group. Since this visit, however, our formerly scanty knowledge of the Maldive Islands has been so vastly increased by Mr. Stanley Gardiner's expedition that the observations of the *Valdivia* are deprived of any value they might otherwise have had. Prof. Chun's ethnological conclusions are not very different from Mr. Gardiner's, but we very much doubt whether the latter author would accept the suggestion that the Maldives are built on a submarine mountain range. On the voyage to Diego Garcia, the very important discovery was made that the Chagos group and the Maldives are connected by a bank in 1100 to 1500 fathoms, this bank being sundered from that on which the Seychelles lie by a narrow channel only. The last section of the voyage in the Indian Ocean, that along the East African coast from Dar-es-Salaam northwards, in 500-700 fathoms, yielded the richest dredgings in the whole cruise.

At the end of the volume are some chapters on the deep-sea animals captured by the expedition and on general considerations concerning the oceanic fauna and flora. The "catch" was, on the whole, very much what might have been expected, and seems to contain many interesting forms, but few startling novelties. Hexactinellid sponges, actinozoa and echinoderms are naturally numerous, and giant forms of ostracoda, cirripedia and larvacea were taken. Deep-sea ctenophores were discovered, and some of the fish are perhaps even more bizarre than those that were already known from the deep sea. Naturally, the collections have not yet been sufficiently examined to enable general conclusions to be drawn from them with certainty, but Prof. Chun seems to incline to the view that the bottom faunas of the Arctic, Antarctic, Atlantic and Indian areas entitle them to be considered as distinct regions, in spite of the marked convergence between the members of the first pair and the identity of many species in the second. The surface fauna, and especially the surface flora, is much more peculiar in each region than the fauna of the bottom, but that of intermediate depths has a very uniform character in all, and, since many animals pass from the surface to lower layers of the water at fixed times of the year, it is possible to account for the cosmopolitan distribution of certain forms. On the subject of bipolarity, Prof. Chun is at present disinclined to pass an opinion.

To sum up in a few words the results of such an undertaking as the German deep-sea expedition is difficult. But it may, we think, be fairly said that not only have two or three discoveries of the first importance been made—such as the soundings in the neighbourhood of the Chagos group and off Walfish Bay, the "tailing off" of the pelagic fauna below 1000 fathoms, and the observations regarding Bouvet Island, but a mass of valuable information has been gathered which, when digested and discussed in the light of the facts accumulated by other expeditions, will set forward very notably our knowledge of the biology and physiography of the sea.

It is impossible to end a notice of this work without referring to the beautiful way in which it is brought out. The print, the margins, the numerous and artistic photographs, and the headpieces quaintly contrived out of representations of sea animals are all beyond praise and can only be made possible in a work issued at the price of the present one by a wide popular appreciation in Germany of the results of the expedition. What sort of public would such a work find in English?

L. A. B.

CHEMICAL ANALYSIS.

Practical Chemistry. By Abegg and Herz. Translated by H. T. Calvert, B.Sc. Pp. xiii+118. (London: Macmillan and Co., Ltd.) Price 6*s*.

THIS little work, which deals mainly with qualitative analysis, is based upon the principles of modern physical chemistry. The equations representing "reactions in solution" are written in the ionic form, thus :—

$$Mn^{\cdot\cdot} + 2OH' = Mn(OH)_2$$
$$Fe^{\cdot\cdot\cdot} + PO_4''' = FePO_4.$$

This method of representing reactions in solution as being entirely dependent upon the "ions" has its advantages, but it also has certain disadvantages. In most text-books the above equations would be represented by the action of definite salts, as, *e.g.*,

$$MnSO_4 + 2KOH = Mn(OH)_2 + K_2SO_4$$
$$FeCl_3 + Na_2HPO_4 = FePO_4 + HCl + 2NaCl.$$

When expressed in the latter form, students are apt to

suppose that the reaction only takes place when the special salt mentioned in the book is used, and if any other salt of the metal is offered to them to say, "but the book says such and such a salt is to be used." On the other hand, when the equations are expressed in the ionic form, as above, the student is perhaps inclined to forget that the anion of the metal and the cation of the reagent also interact.

There are those who look upon the "ionisation theory" as absolutely false and will have none of it. Others, mistaking theory for fact, ridicule all other theories and dogmatically state that *all* difficulties are surmounted when approached by means of the ionic theory. There are many, however, who, without subscribing to the opinions of the extremists, recognise in the ionic theory an extremely useful working hypothesis. Chemical analysis, which is apt to be dry and dull when viewed in —dare we say—the old-fashioned manner, becomes not only interesting, but many of the reactions which were obscure become clear in the light of the ionic theory. Thus, is the action of caustic alkalis upon ferric ferrocyanide (Prussian blue) always clear to students of the old regime? They are told that caustic alkalis decompose the compound according to the following equation :—

$$Fe_7(CN)_{18} + 12KOH = 4Fe(OH)_3 + 3K_4Fe(CN)_6 ;$$

but this does not explain why the whole of the iron is not precipitated as ferric hydrate. Now according to the ionic theory, this would be explained by saying that Prussian blue is dissociated into the cations $4Fe^{\cdots}$ and the complex anions $3Fe(CN)_6''''$ and that only the iron present as the cation is acted upon by the OH' of the potassium hydrate.

The arrangement of the book before us is in some respects peculiar. The student is first instructed how to construct a wash-bottle. This is followed on p. 3 by the preparation of hydrogen. The preparation of oxygen comes after that of hydrochloric acid and sulphuretted hydrogen, and is followed in succession by the methods of preparation of chlorine, sulphur dioxide, carbon dioxide and ammonia.

The analytical portion covers the usual ground and contains the usual reactions. Some portions of the chapter on "theoretical foundations" are far from clear, and we very much question whether the average reader will readily understand the two and a half pages on hydrolysis.

In a pocket at the end of the book there is a rather ingenious blank draught-board with the cations arranged along the top and the anions down the side. The compounds formed by the various ions are to be indicated in their proper squares, and if they are precipitates they may be indicated by shading or by filling in with coloured chalks.

The book has a table of contents, but no index. Even if the German edition was not indexed, surely the translator might have supplied one.

By the way, would it not be well if English writers of chemistry books would arrange always to write the positively charged ion in the same way? As it is, we find it sometimes spelt cation and sometimes kation.

F. M. P.

THE MOVEMENTS OF THE FOOT AND WRIST.

Der Gang des Menschen. iv. Thiel. *Ueber die Bewegung des Fusses und die auf denselben einwirkenden Kräfte.* Von Otto Fischer. Pp. 86 ; 3 plates. (Leipzig: Teubner, 1901.) Price Mk. 5·50.

Ueber die Bewegungen in den Handgelenken. Von Rudolf Fick. Pp. 54 ; with 8 figures in text and 10 plates. (Leipzig: Teubner, 1901.) Price Mk. 6·50.

IT is strange that two men, working side by side within the same university, publishing results of investigations on similar subjects in consecutive pages of the *Proceedings* of the same learned society, should produce two treatises so diverse in nature as those of Dr. Otto Fischer and Prof. Fick. Each employs a peculiar and comparatively new method for the solution of problems which have been thumbmarked by ten generations of anatomists. Dr. Fischer is a mathematician as well as an anatomist, a combination so rare that, in applying the later methods of mathematical physics to the elucidation of the movements of the human body in walking, he has left his colleagues far behind and is almost without audience or critic. Prof. Fick's paper is the result of the application of Röntgen rays to the study of the complex movements of the wrist-joint, a method only comparatively new.

If these authors differ in the methods they have employed they are alike in this, that they are minute, painstaking and accurate, investigating fully every fact for its own sake, with no thought whatsoever as to its utility. Prof. Fick has determined in millimetres the extent and direction of the movements undergone by each of the nine carpal bones during flexion, extension, abduction and adduction of the wrist. In the last paragraph of his paper he sums up his main result as follows :—

"In conclusion I would once more emphasise, what this research has again demonstrated, that the mid-carpal joint is indeed no paltry minor articulation (Kein unwichtiges Nebengelenk) deserving the stepmotherly consideration (stiefmütterliche Berucksichtung) extended to it by most practitioners, but that, for many movements of the hand, it is emphatically the chief joint."

In this conclusion the author, as he himself explicitly states, only verifies the observation made many years ago by Henke. The elaborate and expensive plates, the type and style in which Prof. Fick's work has been published, make an English anatomist envy the wealth of a German society that is able to devote so much of its funds to the elucidation of so small a part of the human body.

In his last contribution to the Kinematics of the human gait, Dr. Fischer dealt with the movements of the lower extremity during the cycle of a double stride; in this, his fourth contribution, he considers the movements of the foot during a corresponding period. The foot is dealt with as if it were detached from and independent of the rest of the body. The forces which act on it during the cycle of a double stride are traced to four sources, viz the muscles (extensor and flexors of the foot), weight of the body, weight of the foot and reaction of the ground. The points at which these forces are applied and the centre of gravity of the foot are determined and diagrammatically represented. The velocity and acceleration of the

centre of gravity of the foot, in the forward, lateral and vertical directions, during the period of a double stride, are determined and diagrammatically represented in three very carefully prepared plates. A. K.

OUR BOOK SHELF.

Ueber angewandte Mathematik und Physik in ihrer Bedeutung für den Unterricht an den höheren Schulen. Nebst Erlauterung der bezüglichen Göttinger Universitätseinrichtungen. Vorträge . . . gesammelt von F. Klein und E. Riecke. Pp. viii + 252. (Leipzig: Teubner, 1900.)

THIS miscellaneous collection falls into two parts. The first consists of eight lectures delivered to teachers in higher schools during a vacation course at Göttingen; of these the first is a sketch of the history of the Physical Institute at Göttingen and the instruction given there; the others deal with various technical branches of applied science in which mathematics plays an important part. The second and probably, to the English reader, the more interesting part of the volume is a reprint of various essays and addresses by Prof. F. Klein, in which he discusses the relation of universities to technical high schools (technische Hochschule). Prof. Klein is clearly of opinion that in Germany these two classes of institutions have become unduly isolated from each other, and should aim at greater solidarity, working loyally for their common welfare.

As one who is interested in the work of both, as well as in the good of the State, he deprecates the tendency in the universities, on the one hand, to divorce the study of mathematics from its practical applications, and in the technical schools, on the other, to take too narrow a view of mathematical science and regard it *merely* as subsidiary and subordinate to the requirements of practical engineering and the like. These tendencies are not wholly unknown in England, and Prof. Klein's arguments and suggestions deserve the attention of our mathematicians and teachers of applied science both in the universities and elsewhere. M.

The Ethical Philosophy of Sidgwick. By F. H. Hayward. Pp. xxiv + 275. (London: Swan Sonnenschein and Co., Ltd., 1901.) Price 4*s*. 6*d*.

A MOST useful though modest and unpretentious little work. In the nine essays of which it is composed the author summarises the main features of the doctrine of the "Methods of Ethics," and discusses from the point of view of an admiring but candid and discriminating reader the principal difficulties of Sidgwick's position. On the vexed question whether Sidgwick is in his ethics fundamentally an egoist or not, Mr. Hayward decides, after a careful examination, in the affirmative, with good reason as the writer of this notice thinks. A good feature of the book is the very full and impartial statement of the controversial arguments against Sidgwick urged by evolutionists on the one side, and neo-Kantians on the other. The care with which the changes in the successive editions of the "Methods" have been noted and allowed for and the thoughtful provision in the opening pages of a summary of Sidgwick's often prolix argument add to the value of a book which all students of ethics will find useful and suggestive. If the book should reach a second edition perhaps the author will tell us more definitely how far he regards the presence of apparently conflicting points of view in the "Methods" as due to excessive care in formulating a delicately balanced and consistent theory, and how far to the attempt to unite together elements which are really irreconcilable. At present he seems to hesitate in his verdict. As a scholar it is to be trusted he will purge future editions of such misspellings as "Königsb*u*rg" and ἐνεργεῖα, and such ugly formations as "perfectionistic" and "introspectionist." A. E. T.

On Traces of an Indefinite Article in Assyrian. By R. Campbell Thompson, M.A. Pp. 31. (London: David Nutt, 1902.) Price 2*s*. 6*d*.

IN this interesting pamphlet the author has attempted to throw some light upon an obscure point of Assyrian grammar, which for some years past has engaged the attention of Semitic scholars, although no completely satisfactory explanation has hitherto been given of it. The point to be explained, and to which attention was first called by Dr. Flemming, is the occasional occurrence of Assyrian and Babylonian words in which the case-endings have been dropped, although the words in question are not in the construct state. The explanation which is now generally accepted, and which was first put forward by Prof. Jensen, assumes that the dropping of the case-endings was a result of the degeneration of the language, a process which finds a parallel in modern Arabic. Mr. Thompson, however, suggests that we may see in the omission of the case-endings traces of an absolute state in Assyrian, similar to that in use in Aramaic; and, assuming this to be the case, it follows that the noun with the case-endings possesses the force of the emphatic state in Aramaic, although it appears to have no equivalent for the post-positive article. Mr. Thompson has arranged his examples to illustrate the rules which hold good for the absolute in Syriac; but he does not run his theory to death, and is fully conscious that the occurrence of variants with the case-endings shows that "the noun need not of necessity adhere to any fixed law."

We cannot here go into detailed criticism of the examples cited, but will only refer to one fact which appears to us to favour the received explanation rather than that here put forward. According to Mr. Thompson, the omission of the case-endings is due to *survival*, and not to degeneration. We should expect, therefore, to find the examples of its occurrence commoner in the early texts than in those of the later periods; as a matter of fact, the reverse appears to be the case. In the Old-Babylonian inscriptions, the case-endings (apart from the use of the construct) are rarely omitted, while the most striking examples of their omission occur in Assyrian and Neo-Babylonian texts. We must congratulate Mr. Thompson on the clearness and brevity with which he has stated his case, and Assyriologists will find the collection of extracts he gives most useful for a study of the question.

Sir Thomas Browne's Notes and Letters on the Natural History of Norfolk. Edited by T. Southwell. Pp. xxvi + 102. (London: Jarrold and Sons, 1902.)

NORFOLK sportsmen and naturalists—and they are many—will be sure to find much to interest them in a work dealing with the fauna of their county as it was in the middle of the seventeenth century, when, as the author tells us, cranes were often seen in hard winters, while bustards were comparatively abundant, although never, perhaps, so common as is often supposed. Sir Thomas Browne, it appears, was a Norwich physician who in early life travelled much. Although not to be compared in point of interest with those of Gilbert White, his letters and notes indicate a keen and shrewd observer of natural history. A large part of the value of the work is, however, due to the editor, who is well known for the keen interest he takes in all that concerns the natural history of the county. Not only has he deciphered with rare skill and patience a vast amount of crabbed MS., but he has contributed a series of foot-notes containing much valuable and interesting information. R. L.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Botany by Indian Foresters.

A GLANCE at the *Indian Forester* for February affords a complete refutation of recent charges brought against the Indian Forest Department for neglect of botany.

This number commences with a most able and interesting account of the forests of the Sudan, written by Mr. Muriel, of the Indian Forest Department, who was sent last year to examine the forests along the Blue and White Niles and the Bahr-el-Ghazel. After travelling for 4600 miles, Mr. Muriel wrote a description of the chief components of the Sudanese woodlands and savannahs, and especially of the cultivation of *Acacia verek*, the Sudanese gum tree, from which last year 80,000 cwt. of gum, valued at 80,000*l*., was delivered at Khartum.

Ordinary timber is valued at 2*s*. a cubic foot at Khartum, while large quantities of wood fuel are required for steamers on the Nile and for locomotives, as well as for culinary purposes, so that the importance of the protection of the forests against incendiary fires and unrestricted grazing and felling is evident. Mr. Muriel has given a very interesting account of the fauna of these regions as well as of their flora, and it is satisfactory to learn that the very able forester and botanist, Mr. A. F. Broun, who has recently assisted Sir D. Brandis at Kew in his new book on the Indian forest flora, has been appointed Conservator of Forests in the Sudan.

In the same number of the *Indian Forester* is a paper by Mr. A. W. Lushington, of the Indian Forest Service, on the identification of seventy-four Indian species of Loranthaceæ by means of their ramification and leaves. He states that it is not uncommon in southern India to find forests completely ruined by these parasites. "The vegetation, weakened by forest fires, is incapable of battling with these pests, and as the better species of timber trees are less well supplied with sap than the inferior species, the former are the first to be killed." As the Loranthaceæ are classified by their flowers and the latter exist only for a short period, while the forest officer has a very large district to supervise and may not meet with some of the species in flower, the utility of Mr. Lushington's work is apparent.

Babu Upendranath Kanjilal, of the Indian Forest Department, has just published a most excellent and handy volume on the local forest flora of the School Circle, North-West Provinces of India, where the forests range in altitude from 1000 to 10,000 feet above sea-level. This work is also referred to in the February number of the *Indian Forester*, in which is also found a list, systematically arranged, of trees and shrubs in the Jerruck division of Sind, by Mr. G. K. Betham, of the Indian Forest Department.

Any habitual reader of the *Indian Forester* will see that Indian forest officers pay considerable attention to biology, chiefly as regards plants and insects; but, after all, their chief duty is the economic management of the Indian forests, and the great amount of work this involves and its value to the Indian Empire can be appreciated only by those who have given a fair attention to forestry in all its bearings.

Besides British India and the included and adjoining native States, such as Cashmere, Indian foresters are now employed in Siam, the Philippine Islands, Cape Colony and the Sudan. Owing to the great devastation of woodlands in the Transvaal and Orange River Colonies, which is graphically described in a recent number of the *Revue des Eaux et Forêts* (the *French Forestry Magazine*), it is to be hoped that a sound administration of forestry may soon be established in these territories.

Coopers Hill, February 24. W. R. FISHER.

Cherry Disease.

MY attention has just been called to a letter in your issue of January 30 from Sir W. T. Thiselton-Dyer, which gives the strongest possible confirmation to my contention that a fully equipped State Agricultural Laboratory is a national desideratum, and that in this respect Britain is behind other countries.

Your correspondent implies in his letter that with Kew and the British Museum in existence there is no pressing need for any other institution. The Director's letter proceeds to relate what Kew has done "promptly and in ordinary routine" for the protection of the British farmer against the cherry disease; and the sum of it is that in November, 1900, Kew answered an inquiry from Mr. A. O. Walker by telling him that the fungus on the cherry leaves sent by him was *Gnomonia erythrostoma*. The next step taken by Kew—and the only public one—is the director's ungenerous criticism of what has been done meanwhile by the Royal Agricultural Society. (Mr. Walker's letter to the *Gardeners' Chronicle* in May, 1900, was apparently his own private action, in no way initiated by Kew, and was certainly not an official step.)

A pathogenic fungus can be named at any time in ordinary routine for an individual inquirer either at Kew or at the British Museum; but this is the smallest part of the work of a State Agricultural Laboratory.

The Royal Agricultural Society of England, which—public-spirited though it be—is not a State-supported institution, took some practical steps. It was not until December 1900 that a specimen of the cherry disease was received at the laboratory of that Society, and at the next council meeting on February 5, 1901, I reported on the disease. This report was published in the agricultural papers of that and the following weeks, and was widely distributed in leaflet form by the Society among the Kent cherry-growers, to its own members and to non-members indiscriminately. A conference with the cherry-growers at Maidstone followed, and the result has been that the disease was carefully observed, and sufficient information reached the Society's laboratory to enable the publication in its *Journal* of a detailed account of the disease as it has appeared in England. I regret to add that I have received specimens of wild cherry from Somerset attacked by the Gnomonia.

Any benefit which may conceivably have come to the British farmer from Kew in this matter accrued indirectly in May through the action of a private individual. The Royal Agricultural Society had already in February taken the valuable practical steps which in most other countries would have been the duty of a State Agricultural Laboratory.

I need not trouble you in regard to your correspondent's kind correction of an intentionally indefinite description in my report, which has been put right in its final form, issued ten days before his letter was published; nor with his other criticisms upon your report of the meeting of the Royal Microscopical Society, criticisms which to an intelligent and careful reader answer themselves. WILLIAM CARRUTHERS.

44 Central Hill, Norwood, February 22.

MR. CARRUTHERS' letter is open to some criticism. Taking it, however, as it stands, it proves conclusively that in the case of the cherry-leaf disease everything has been done by existing agencies that was practically possible. This particular instance therefore affords no basis for the demand for a State Agricultural Laboratory.

As I have already stated, the disease does not appear to have been brought under the notice of the Board of Agriculture. Had it been so, that department, if it had seemed desirable, could have relieved the Royal Agricultural Society of the task of preparing and distributing a leaflet. Mr. Walker, however, points out in NATURE for February 6 (p. 318) that "the disease has almost disappeared, though no preventive measures such as stripping the leaves were taken."

The object of my letter was to make a protest against the present tendency to demand fresh State machinery instead of endeavouring to increase the usefulness of that which already exists. W. T. THISELTON-DYER.

Kew, February 26.

Identity of Negative Ions Produced in Various Ways.

FROM the results of some experiments which I have recently made, it can be shown that the negative ions produced in various gases by Röntgen rays, or by collision, are all identically the same and are smaller than the molecules of hydrogen.

The following results have been established by the researches on this subject which have been already published (J. S. Townsend, *Phil. Mag.*, February 1901; J. S. Townsend and P. J. Kirkby, *Phil. Mag.*, June 1901; P. J. Kirkby, *Phil. Mag.*, February 1902):—

(*a*) The negative ions produced in a gas by Röntgen rays

generate other ions by collisions with the molecules of the gas when they move sufficiently rapidly.

(*b*) For any gas the negative ions which are generated by collisions are the same (having the same properties over wide ranges of force and pressure) as those which were generated by the rays.

(*c*) If α is the number of negative ions generated in a gas by one of these negative ions moving through one centimetre, then $\alpha = pf\left(\frac{X}{p}\right)$, where p is the pressure of the gas and X the electric force acting on the ion.

(*d*) The free paths of the negative ions are long, compared with the free paths of the molecules, so that their linear dimensions must be smaller than those of the molecules.

From a comparison of the properties of positive and negative ions, it can be seen that the mass of the negative ion must be small compared with that of the positive ion.

The values of α were determined for large ranges of pressure and electric force for air, carbonic acid and hydrogen, and the functions f have been represented graphically by three curves. Let f_1, f_2 and f_3 denote the functions f found for air, carbonic acid and hydrogen respectively as determined by the experiments with Röntgen rays.

The results which I have to add to these were obtained by finding the conductivities of gases between parallel plates when one of the plates is illuminated by ultra-violet light.

The experiments have led to the following conclusions:—

(*a'*) The negative ions set free from a zinc plate when ultra-violet light falls on it generate other ions by collisions with molecules of air, carbonic acid or hydrogen.

(*b'*) The negative ions thus generated by collision in the gases have the same properties (over large ranges of pressure and electric force) as the ions generated by the light from the zinc.

[Hence these four kinds of ions are identical, viz., the ions given off from the zinc plate and the negative ions which they produce in air, carbonic acid or hydrogen. These negative ions may be denoted by the letter Z.]

(*c'*) If α' is the number of ions which one of the Z ions produces per centimetre by collisions with molecules, then α' is connected with the electric force and the pressure by an equation of the form $\alpha' = pf'\left(\frac{X}{p}\right)$. The three functions f_1', f_2', f_3' as determined in this manner for air, carbonic acid and hydrogen are equal respectively to the corresponding functions f_1, f_2, f_3 as determined by the experiments with Röntgen rays. The equality extends over the whole ranges of pressures and force which have been examined.

Consequently the negative ions generated by Röntgen rays in a gas are precisely the same as the ions set free from a zinc plate by ultra-violet light.

If it be questioned that the identities $f_1 \equiv f_1'$; $f_2 \equiv f_2'$; $f_3 \equiv f_3'$ are sufficient to justify this conclusion we may proceed to establish the proposition in the following manner:—

The charges on negative ions produced by Röntgen rays in any of the gases under consideration have been shown to be equal to the charge on a negative ion given off from a zinc plate by ultra-violet light (J. S. Townsend, *Phil. Trans.* 1899 and 1900).

For simplicity, one of the gases may be considered, air, for example. Let m be the mass and e the charge on a negative ion R produced in air by Röntgen rays, and let m' and e' be similar quantities for an ion Z produced by the aid of ultra-violet light.

Since the maximum values of f_1 and f_1' as determined by the larger values of $\frac{X}{p}$ are equal the two kinds of ions R and Z must produce the same number of collisions per centimetre so that they have the same free paths. For any force X, the kinetic energy that the R and Z ions acquire along their free paths must be equal since their charges are equal. At the end of a path of length x the value of $\frac{mv^2}{2}$ or $\frac{mv'^2}{2}$ is equal to Xex.

Hence we have the equation $mv^2 = m'v'^2$, v and v' being the velocities of the ions R and Z before collision.

A second independent equation is obtained when we consider the identity $f_1 \equiv f_1'$.

The chance of producing new ions by collision is not determined by the energy of the colliding ion. If this were the case, the positive ions would produce others by collision under an electric force X if their mean paths became equal to the mean paths of the negative ions when they generate others under the action of the force X. It is easy to show that the positive ions do not acquire the property of producing others by collision even when their free paths are much longer than those of the negative ions when they are giving others by collisions. The negative ions therefore possess this ionising property in virtue of the large velocities they acquire along their free paths. It is therefore evident that the function f involves the mass and velocity of the colliding ion in some form which is not reducible to the product $m \times v^2$. The equality of f_1 and f_1' for the same values of e, X and p supplies us with an equation between m, v, m', v', of the form $\phi(m, v) = \phi(m', v')$. Combining this equation with the equation $mv^2 = m'v'^2$, we see that $m = m'$ and $v = v'$.

Hence the masses of the two ions R and Z are the same as well as their free paths and charges. We thus see that it is possible, by various methods, to detach negatively charged particles from the molecules of gases which are small compared with the molecules, and that the particles which are detached are the same from whatever gas they are removed.

The Recent Fall of Red Dust.

SOME observations made last autumn in Cornwall may throw light on the fall of dust in South Wales. On September 2, during gusty weather with squalls from the E.N.E., I watched from my window at Carbis Bay (270 feet above the sea) puffs and swirls of dust rising from the desert-like flat at the mouth of the Red River. The dust-cloud rose above the top of Godrevy Towans (230 feet), nearly blotted out Godrevy Lighthouse and then spread in a well-defined belt across St. Ives Bay for more than three miles to near St. Ives Head, which it must have passed, though this part of the track was invisible from my point of view. A fortnight earlier a similar observation had been made under identical conditions by Mrs. Reid. On neither occasion did the wind reach the force of a gale, it was merely a strong, dry east wind.

The red mud which gives its name to the Red River is mainly slime produced by the crushing of the tin-ore in the stream-tin works. This mud spreads far and wide over the alluvial flats and along the sandy shore; when it dries it forms an almost impalpable dust. Much of this dust is mixed with the Cornish sand-dunes, and drifts to and fro with the shelly sand, which forms the main part of those dunes. If the dust-falls in South Wales are of Cornish origin, the material will probably contain a good deal of finely powdered schorl, which mineral occurs abundantly in the tin-ore.

CLEMENT REID.

The Validity of the Ionisation Theory.

THE number of NATURE which appeared on January 30 contains an abstract of a paper by L. Kahlenberg entitled "The Theory of Electrolytic Dissociation as viewed in the Light of Facts recently Ascertained." In the paper referred to is a kind of summary of observations which have been made on non-aqueous solutions, from the consideration of which the author draws the conclusion that the electrolytic dissociation theory is untenable in the case of non-aqueous solutions.

In view, however, of the generally accepted opinion that this theory is in good accordance with experimental observations on aqueous solutions, Kahlenberg has been led to investigate such solutions more closely. As the result of a large number of boiling-point, freezing-point and conductivity determinations, the conclusion is drawn that "the difficulties which the theory of electrolytic dissociation encounters in explaining the phenomena in aqueous solutions are really insurmountable."

One of the chief reasons for this inference appears to be that the series of molecular weight values calculated from the cryoscopic and ebullioscopic measurements at different concentrations of the solutions are irregular. As an example, it is found that in the case of solutions of magnesium sulphate, the calculated molecular weight, which even in the most dilute solution is greater than the theoretical value, increases at first with the concentration, passes through a maximum and then decreases, attaining a value which would correspond to electrolytic dissociation only in the most concentrated solutions. The author does not state in what manner these "molecular

weights" have been calculated, but presumably the ordinary formula has been employed. It is important to note that in seven out of the nine boiling-point measurements carried out with magnesium sulphate, the concentration of the solution varies from about 15 per cent. to over 40 per cent. In other experiments with solutions of cane sugar, concentrations varying from 20 grams to 290 grams of sugar per 100 grams of water have been employed, the calculated "molecular weight" (theory = 342) decreasing from 360 to 212 at the highest concentration.

To attribute to the numbers calculated by means of the simple boiling-point formula for solutions of such concentrations the significance of molecular weight values can scarcely be regarded as justifiable. In so far as the ordinary freezing-point and boiling-point formulæ rest on a thermodynamical basis, they only hold good for ideal solutions; for such solutions the formulæ in question will give molecular weight values, but it has yet to be shown that the numbers calculated by Kahlenberg from his experiments can be taken as representing molecular weights.

For moderately concentrated solutions which no longer satisfy the requisites of an ideal solution, distinguished by the properties that no heat is evolved or absorbed and no change of volume takes place when it is diluted, Ewan, amongst others, has deduced an expression connecting the osmotic pressure with the lowering of the freezing point, the formula resting on a thermodynamical basis. This formula, when used for the calculation of molecular weights, gives, even with solutions containing as much as 40 per cent. of cane sugar, values scarcely differing from theory (342), whereas the simple freezing-point formula for a solution of the concentration mentioned gives 275.

Another reason advanced by Kahlenberg to prove the inadmissibility of the ionic theory is the lack of agreement between the numbers representing the degree of dissociation as calculated from the conductivity on the one hand and the freezing- or boiling point on the other. If for the reasons previously stated the calculations based on the boiling-point and freezing-point measurements have little significance so far as the ionic theory is concerned, it is obviously impossible to effect the required comparison. Furthermore, it seems questionable whether the numbers calculated by the formula $\alpha = \frac{\mu_v}{\mu_\infty}$ really represent degrees of dissociation. The formula involves the as yet unproved and scarcely probable assumption that the ionic velocities are the same in solutions of all possible concentrations. The development of the ionic theory is by no means conditioned by the validity of such a formula. So far as Kahlenberg's measurements are concerned, the comparison between the results of the boiling-point and conductivity measurements is moreover, impossible, except in the case of the binary salts, since the range of concentrations employed is quite different.

Although, therefore, the publication contains a large number of valuable empirical data, yet it cannot be allowed for one moment that the ionic theory has been shown to be untenable. It is far from the wish of the writer to minimise the difficulties which do admittedly confront the theory of electrolytic dissociation. It must not, however, be supposed that the theory has received its final and complete form; the possibilities of its rational expansion and development to explain existing irregularities are far from being exhausted. A warning note may be sounded against a too ready assumption that new experimental data prove the untenability of the theory without very careful consideration of what exactly is, and is not, stipulated by the theory. H. M. DAWSON.

Birds attacking Butterflies and Moths.

I WAS much interested in the letter in NATURE of January 16 on the frequent capture of butterflies in India by the King Crow, as some years ago I experimented with a captive bird of this species, and found that it avoided "warningly-coloured" butterflies when possible, and was deceived by mimicry (*J. A. S. B.*, ii. 1897, p. 651).

With regard to the capture of butterflies by bush-haunting birds which do not take them on the wing, I pointed out as long ago as 1895 (*J. A. S. B.*, ii. 344) that the common Babbler *Crateropus canorus* was likely to meet with butterflies in repose, and proved experimentally that it dislikes the "warningly-coloured" species. But I could then give no positive evidence that it does, as a matter of fact, attack butterflies on its own account, though it will take them if thrown in its way.

I therefore give here the results of a few experiments which, in my opinion, show that this bird also naturally preys on butterflies.

In March last year I gave to a wild-caught bird of this species a *Danais limniace* together with a Junonia. The bird took and ate the latter; I then removed the Danais.

I have just now been offering three specimens of *Danais genutia*, together with three plain brown butterflies, to three wild-caught adult Babblers placed in separate cages.

Two of the birds disregarded the Danaids until they had eaten the other butterflies, and then did not attack them eagerly or eat them (except the abdomen in one case), although they had no food in their cages at the time.

I conclude, therefore, that they were last year's birds, which knew and disliked *D. limniace*, and the present two *D. genutia*, from previous experience in catching and tasting butterflies when wild.

The third bird experimented with to-day attacked its specimen of *D. genutia* first, but soon left it to eat the other butterfly given; nor did it tear the Danais to pieces as did the others, although, like them, it had no other food in its cage.

Either, then, this bird had forgotten its wild experience, or, what is more likely, it had never happened to catch *D. genutia*, and so knew nothing about this species, which it evidently disliked, from what has been said above, although it was not impressed by the "warning colours."

In my previous experiments with this Babbler I did not observe the same precautions, when *first* offering the butterflies to the birds, as I did in these later experiments, so that the results I obtained, although sufficiently demonstrative of the preferences of the species, threw no light on the individual experience of the specimens experimented with. On Prof. Arrhenius' Theory of Cometary Tails and Auroræ.

IN the more or less popular accounts which have recently been given of Prof. Arrhenius' theory of cometary tails and the auroræ, it is generally stated that the smaller the diameter of the corpuscle upon which the light is falling the greater the excess of light-pressure over gravitational force. This explanation, however, holds only so long as the diameter is greater than the wave-length of light. If the diameter becomes of the same order as the wave-length, the ratio between light-pressure and gravitation follows an entirely different law. This has recently been demonstrated by Prof. Schwarzschild by an exhaustive mathematical treatment of the question in a paper entitled "Der Druck des Lichtes auf kleine Kugeln und die Arrhenius'sche Theorie der Cometenschweife" (*Sitzungsberichte* der k. b. Academie der Wissenschaften zu München, 1901, Heft iii.). The conclusions arrived at in this paper are of considerable importance in so far as they show that the effect of gravitation is exceeded by that of the pressure of light only so long as the diameter of the corpuscle is greater than about $0 \cdot 07 \mu$. For this limiting value the two forces are exactly balanced; but for smaller values of the diameter the light-pressure becomes rapidly less, so that it is then always exceeded by gravitation. It would appear from Prof. Schwarzschild's computations that the globular corpuscles thrown off in the tails of comets should have diameters not smaller than $0 \cdot 07 \mu$ and not exceeding $1 \cdot 5 \mu$, supposing the specific gravity of the corpuscle to be that of water. Now these values far exceed the limits assigned to the dimensions of the molecules. According to our present knowledge, based on

theory as well as on experiment, we are forced to conclude that the diameter of a molecule cannot be larger than $0{\cdot}003\mu$. On the other hand, the specific gravity of a molecule of air, for instance, appears to be very great, viz. five times that of water (see Meyer, "Die kinetische Theorie der Gase"). This maximum value of the diameter of a molecule is so enormously smaller than the values demanded by Prof. Arrhenius' theory that the latter appears to be incompatible with any assumption which regards the cometary matter as being of a gaseous constituency. In order to explain the repulsion of matter in the tails of comets by the pressure of the sunlight, this matter must be assumed to consist of small drops, each of a bulk sufficiently large to harbour at least one million molecules within its bounding surface. Whether such an assumption can be justified appears to me very doubtful. At any rate, Prof. Schwarzschild's profound mathematical investigation makes it absolutely clear that the idea of minute electrically-charged corpuscles—of about one-thousandth the size of a hydrogen atom (see *Observatory*, February 1902, p. 103)—being propelled by the sun's light towards the earth and causing the various phenomena of auroræ, Gegenschein, &c., receives no support from the mathematical point of view. But, even apart from these difficulties, it can hardly be said that the ingenious theory of Arrhenius settles the question as to the nature of the force acting on the cometary matter. So far it offers no explanation of the remarkable phenomenon of the contraction of the coma with the approach towards the sun. Doubtless this *contractile* force is also of solar origin. But can it be identified with the force which repels the cometary matter in the direction of the radius vector? It appears to me that the theory in its present form only removes one difficulty by introducing several others. J. HALM.

Experimental Geometry in Secondary Schools.

IN the report, in your issue of February 27 (p. 404), of a meeting of the Mathematical Association, it is stated to have been the opinion of most speakers that the study of demonstrative geometry should be preceded by a course of work with ruler, compasses and protractor, in which simple measurements and constructions form the chief part. The note continues with the statement that such a course has been adopted in Scottish schools, and in English elementary schools and kindergartens.

May I venture to point out that there are a considerable number of secondary schools where this kind of work forms a regular part of the curriculum in the lower mathematical classes (this has, for instance, been the case here for the past three years), and that it has been recognised as a valuable medium by which a boy's interest may be aroused in geometry before he is introduced to the very irksome and difficult task of assimilating Euclid's phraseology? C. A. RUMSEY.

Dulwich College, March 5.

The Zodiacal Light.

THE zodiacal light was visible here last night at 7h. 30m. p.m. The base at the horizon was about 16° wide; the axis of the cone pointed towards the Pleiades, but the apex did not reach much beyond α Arietis. At 7h. 45m. it was brightest; at 8h. it had faded out, possibly on account of mist in the air, as a fog set in about an hour afterwards. J. P. MACLEAR.

Contributions to Anatomical Journals.

PROF. HUNTINGTON, of Columbia University, has called my attention to a paragraph in an article on "A New Journal of Anatomy" in your issue of January 9 to which he, naturally, takes exception.

In justice to Prof. Huntington, I beg leave to state that he had no part whatever in the recommendation, acceptance or production of either of the papers on which your critic animadverts.

The first of these was accepted by one of my British co-editors and sent to me for publication, the author supplying the plates. For the second I, solely, am responsible.

The method of the higher criticism is not always trustworthy when its results can be checked by contemporary history.

ALEX. MACALISTER.

New Museums, Cambridge, February 14.

I REGRET to say that my statement concerning Prof. Huntington and the origin of the paper which I described was based on hearsay, and in face of Prof. Macalister's letter I can but tender Prof. Huntington my sincere apologies.

I am relieved to find that the author provided the plates.

February 26. THE WRITER OF THE REVIEW.

FURTHER DEVELOPMENTS IN WIRELESS TELEGRAPHY.

SINCE the article which appeared in NATURE last week was written, some further details concerning Mr. Marconi's Transatlantic signalling have been published, and also another success attained by the inventor has been announced. The information with reference to the latter point is contained in a telegram from the New York correspondent of the *Daily Telegraph*, which appeared in that paper on Monday last. Messages, it seems, were transmitted from Poldhu to the *Philadelphia*, whilst that ship, on board of which was Mr. Marconi, was on her way from this country to New York. Five messages in all were received, the first when the *Philadelphia* was at a distance of 250 miles from the Lizard, and the last on February 25, when the distance had been increased to 1551 miles. In addition, a signal of the much-talked-of letter "S" was received at a distance of 2099 miles. The news is confirmed by the following telegram from Mr. Marconi, which is contained in a letter from the Wireless Telegraph Co. to Wednesday's *Times*:—

"Health good. Received messages 1551 miles. Test letter at 2099. All on tape receiver. Records duly attested by ship's officers.—MARCONI."

The chief interest of these results lies in the fact that the received messages, including the signal "S," were recorded on the tape of the receiving apparatus, and not merely heard in the telephone, as was the case with the Transatlantic signal. Mr. Marconi must feel greatly gratified at thus having visible record of the success of his experiments in this instance, as it removes the possibility of the suggestion that he was deceived by the wish to hear being father to the thought that he heard. Messages were naturally only transmitted in the one direction, as the transmitting apparatus on board the *Philadelphia* was not so powerful as that at the Cornwall station.

The further details as to the Transatlantic signalling to which we referred above are published in an article on Mr. Marconi in this month's *Century Magazine*. This article, the proofs of which have been read by Mr. Marconi, contains an account of the development of wireless telegraphy, and is illustrated by a number of interesting pictures. We reproduce here a photograph of the transmitting station at Poldhu from which all the long-distance signals have been transmitted, which shows very clearly the group of twenty masts, each of which is 210 feet high. The power is obtained from an alternate-current generator of 38 horse-power. There is thus more than two hundred times as much power used as in the signalling apparatus installed on board ships using the Marconi system. It will be noticed that in the later work development has taken place rather along the lines of increasing the output of power than of using higher masts. Mr. Marconi, it is said, considers that a mast about 200 feet high is the most suitable from all points of view, and in some remarks, which we quote at the end of this article, states that he thinks that any desired distance could be bridged given sufficient power.

A good deal of objection is still raised on the question of syntony, and it is pointed out that although tuning has been obtained with sufficient accuracy to prevent interference, this does not prevent the picking up of messages by an outsider who should experiment with a

special view to finding the correct tune, or of the interference with signalling in a similar way. This fear is, however, somewhat imaginary, as it is doubtful whether such an enterprise would be commercially successful, and it is inconceivable that anyone should devote his energies to its realisation purely out of malicious rivalry. Even in war time, we think, it would hardly repay the labour, and, moreover, Marconi's system now promises to be of more use in peace than in war. It may be remarked, too, that syntony—especially syntony so thorough as that described by Prof. Fleming eighteen months ago, when two distinct messages were sent and received by the same transmitting and receiving wires—opens up the possibility of multiplex wireless telegraphy, which would be equivalent to a great increase in the speed of signalling.

We may finally quote some remarks made by Mr. Marconi on his arrival in America after his success with the experiments on the *Philadelphia.*

"I believe," he said, "that the distance at which a wireless message may be sent depends only on the power of the sending station. I think it possible to send a message entirely around the world, to start the message eastward around the globe, and to receive it at the same station from the westward.

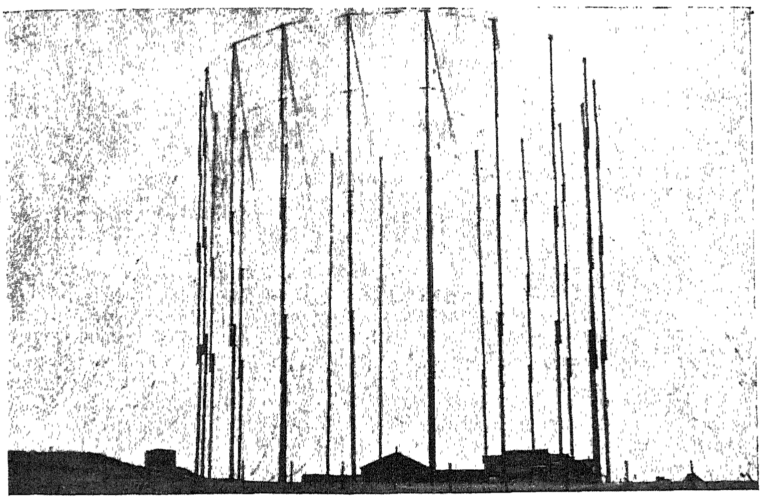

FIG. 1.—View of Poldhu Station, Cornwall, whence the signals came to Marconi at St. John's.

"I now know that the curvature of the earth does not in the least affect the waves. Many people who have reasons for hoping so have said that this would prove a fatal defect to the system, but it is not so. During the voyage I carried out a number of experiments which I had long wanted to make, but which I had never attempted before. You must pardon me for not disclosing their nature. All I can say is that they were eminently satisfactory to me." M. S.

THE METROPOLITAN HOSPITALS AND VIVISECTION.

WE have recently received the new edition of a pamphlet entitled "The Metropolitan Hospitals and Vivisection, a Guide for the Charitable in the Disposition of their Gifts and Bequests," by the Hon. Stephen Coleridge. The pamphlet begins with a prologue which consists of a short phrase snatched without any context from a speech delivered by the Home Secretary. Owing to the shorn character of this phrase, which stands out grotesquely framed with interpolations, we are unable to say what the Home Secretary really meant. The author, however, draws an inference which certainly is not justifiable, viz. that serious operations without anæsthetics necessarily involve the torture of animals. Whether this is so or not depends entirely upon what is meant by a serious operation and what is meant by torture, concerning neither of which is a word said. By torture we certainly do not mean mere momentary pain.

The main object of the essay is, however, threefold. In the first instance Mr. Coleridge, presumably satisfied, from his prologue, that the legalised torture of animals by so-called vivisectors actually takes place, and that no matter what its object may be is unjustifiable, classifies all metropolitan hospitals according to their supposed connection with vivisection. He further appeals to all those who have money to give, to enrich only those hospitals printed in plain type in his list, being the ones which at the present time are entirely free from vivisection and vivisectors. The second object of the monograph seems to be to denounce as diversion of charitable funds from their legitimate object any payment from the hospitals to the medical schools attached to them. There is also in addition to this an assumption that such payments are practically for the subsidy of vivisection so-called, and a further appeal to the charitable on this count. The third object is apparently to impugn the integrity of the committee for the distribution of King Edward's Hospital Fund.

First, then, according to Mr. Coleridge, the charitable should give only to those hospitals which at the time of their bequest are entirely free from all vivisection connections. It must be at once pointed out that this is a somewhat complicated affair, and will require very careful study upon the part of the donors, in that the staffs of hospitals change, and, further, a man of science once a vivisector is not always a vivisector. Since he does not vivisect for amusement, he does so only when he has a definite problem in his mind, and accordingly arranges a series of experiments capable of giving him a definite solution. From this it follows, as indeed the list in this pamphlet shows, that a hospital intimately connected with vivisectors one year may be entirely emancipated from them the next, and therefore that the terms of an anti-vivisection bequest will require alteration from year to year.

The hospitals at present free from all vivisection taint, according to the pamphlet before us, contain 4516 beds; of these 4500 beds, ethically, according to Mr. Coleridge, eligible for the gifts of the charitable, 1109, or practically one quarter, are devoted to lunatics or idiots. Now this fact surely should have been clearly stated, and also its corollary, viz., that should the charitable decide to support only those hospitals satisfying Mr. Coleridge's requirements for eligibility, one quarter of their subscription will be devoted to the maintenance of lunatics or imbeciles, extensive provision for which is already supplied out of the rates. Further, another fact of which the charitable, in Mr. Coleridge's sense, should be cognisant is, that of the remaining 3000 or so beds no less than 500, or approximately one-eighth of the original total, are devoted to the maintenance of incurables. Two-eighths of the subscriptions of the charitable should, according to Mr. Coleridge, go to lunatics, one-eighth to incurables. Of the remaining 2900 beds, 300 either belong to local cottage hospitals or are devoted to small-pox or other infectious diseases. The former hospitals

will receive a large measure of support, at least in many cases, from those locally interested in them, and accommodation for infectious diseases other than small local isolation hospitals is dealt with out of the rates. From this it follows that of any subscription given according to Mr. Coleridge's lines, little more than one-half will be devoted to what the average charitable man regards as the essential function of a hospital, viz. the treatment of acute medical and surgical disease and the rendering of the unfortunate subject of it capable of returning to earn his, and very often his family's, daily bread. We think it would have been fairer and of more real help to the charitable layman whom this pamphlet pretends to guide had these considerations been clearly set forth. Let him, then, now clearly understand that had he followed Mr. Coleridge's advice during, for instance, the year 1900, to which the figures in their entirety apply, and specifically stated that his money should go to no hospital connected with vivisection, practically half of it would have been "diverted" from the legitimate object of his charity.

To pass to a question which certainly does not possess the merit of novelty, viz. the so-called diversion of hospital funds to the medical schools attached to them, we would simply repeat what we have said before, that this is no diversion at all, no more diversion than the salary paid to a hospital gate-porter. The "managers" of the large hospitals are shrewd business men, we think more shrewd even than Mr. Coleridge, and they know full well that the efficacy of a large general hospital depends *inter alia* upon there being a medical school attached to it? The clinical teachers, demonstrators and students tend the sick and teach the nurses, thus securing efficient ones; the more purely scientific departments of the school help, each using the methods in which they are individually expert, in the elucidation of those obscure cases often demanding the technique of all. By these means the physician or surgeon becomes possessed of a knowledge of facts enabling him to adopt lines of treatment which mitigate pain, minimise the havoc of disease, and not seldom actually save life. Under the present regime these services are rendered by the medical schools gratuitously: sums granted towards the maintenance of these schools cannot be said to be diverted from the use of the sick; the sick get the full benefit of them.

If we now turn to Mr. Coleridge's impugnment of King Edward's Hospital Fund Committee, we shall arrive at some interesting deductions from the figures provided for our enlightenment which were not pointed out by the author. Mr. Coleridge has noted the fact that the allocation of the hospital fund grants per bed was greatest in the case of the hospitals possessing medical schools, and thus laboratories. In the case of the other hospitals, those which had upon their staff vivisectors received larger grants than those entirely unconnected with vivisection. *Post hoc propter hoc*, in other words, Lord Lister especially, and his colleagues to a less degree, have wilfully used King Edward's Hospital Fund for the purpose of endowing vivisection.

It is certainly to be assumed that King Edward's Hospital Fund was not intended for the endowment either of lunatic asylums or homes for the incurable, or local cottage hospitals, or local isolation or small-pox hospitals, which certainly ought to be provided for out of the rates. To no hospitals of this kind did the Committee, and we venture to think quite rightly, make any grant. We do not mean for one moment to infer that such institutions are not worthy of support, but the ordinary subscriber to a hospital fund does not include under that category either lunatic asylums or homes for incurable or dying patients. If, however, we exclude the above institutions from our calculations, how are Mr. Coleridge's figures affected? The facts are these: that (taking Mr. Coleridge's remaining figures as correct) hospitals with medical schools and laboratories attached received 5*l*. 8*s*. 9*d*.; hospitals with no medical schools, but connected in the special sense of the pamphlet with vivisectors, 4*l*. 14*s*. 2*d*.; and hospitals entirely unconnected with vivisection, 5*l*. per bed. In other words, while hospitals connected with medical schools received by a small amount the most per bed, those hospitals which were entirely unconnected with vivisection received more than those to the staffs of which so-called vivisectors were attached. There is, therefore, so far as the grant per bed is concerned, no ground for Mr. Coleridge's charges.

If we look into the matter more minutely we shall see that in the details of each hospital grant there is even less reason to suspect that vivisection had anything whatever to do with it. If we compare the maximum grants per bed in the hospitals as classified by Mr. Coleridge, we shall find the largest grant of all hospitals connected with vivisection laboratories was 8*l*., or approximately 8*l*., per bed, given to Guy's, a hospital in need of funds, and one, of course, doing magnificent work. If we take two hospitals entirely unconnected with vivisection, we find in the case of the N.W. London Hospital a grant of 10*l*. per bed, and in the case of the Royal Free Hospital a grant of 9*l*. per bed. How can it be argued, in the face of these figures, that preference was given to hospitals connected with vivisection *qua* vivisection? We do not wish to impugn Mr. Coleridge's motives, but the ingenious way in which he has attempted to mislead the charitable layman by the pamphlet before us is, in our opinion, in the highest degree reprehensible.

The end of this document in which truth is so distorted is devoted to a personal defamatory attack upon Lord Lister. This attack, we are pleased to see, is somewhat modified for the better since we last reviewed it; concerning it we must refer the reader to our former article. The monograph concludes with an epilogue consisting of a repetition of an invective, couched in Mr. Coleridge's most offensive terms, against science, and sounds like some papal bull of the middle ages anathematising that knowledge which was eventually to liberate mankind from filth, superstition, suppression and ignorance. Medical science, which perhaps has done more than any agency under Heaven to alleviate the sufferings of mankind, is ruthlessly termed "malignant." Invective is not argument, neither is calumnious opprobrium logic.

The charitable subscriber to London hospitals will see to what "diversion" his subscriptions will be subject if he follows the advice of Mr. Coleridge. It is to be hoped, and indeed to be expected, that he will give as he has done before, leaving the disbursement of his bequests to representatively elected committees of experts who, neither prompted by political motives nor influenced by misplaced and maudlin sentimentality, will assuredly allocate them to the most urgent wants of the sick.

THE PROPOSED BRITISH ACADEMY.

THE following text of the petition presented to the Privy Council by the council of the Royal Society in favour of the establishment of a British Academy appeared in the *Times* of February 27:—

TO THE KING'S MOST EXCELLENT MAJESTY IN COUNCIL.

The humble petition of the President and Council of the Royal Society.

Showeth—

That your petitioners pray that the petition which has been presented to His Majesty in Council praying for the grant of a charter of incorporation to "The British Academy for the Promotion of Historical, Philosophical and Philological Studies" be granted.

Your petitioners are led to take this step both for the general reason that the granting of such a charter will, in their opinion,

be for the great good of learning, and also for the special reason set forth in the following statement:—

In 1899 an International Association of Academies, composed of the leading learned bodies of many countries, was formed, the Royal Society taking an active part in its formation. Since the various studies cultivated by the constituent academies could be readily divided into two categories—(1) those of mathematical, experimental and natural science, and (2) those of philology, history and philosophy—the association established within itself two sections, one for the former the other for the latter studies, and drew up statutes in accordance with this division.

The Royal Society is, at the present time, concerned with studies of the former category only; and since no other learned body of the United Kingdom dealing with the studies of the other category belongs to the association, it has come about that while most other countries are represented in both sections, either by two academies or by an academy taking charge of studies of both categories, this country is represented in one section only.

In other words, in this country there does not exist, as in most other countries, an academy or other organisation of the rank of the several academies constituting the association in question, charged with the duty of fostering studies of the second category. The Royal Society, therefore, thought it to be its duty to bring this fact, regrettable on general grounds, quite apart from representation in the International Association of Academies, to the notice of certain persons in this country eminent in those studies.

A correspondence with these eminent persons resulted in the Royal Society being invited to consider how this regrettable state of things could be remedied, and in particular whether the Royal Society was able and willing to include the studies in question within its sphere of action.

The president and council of the Royal Society appointed a special committee to consider and report upon the matter, instructing the committee not to advise the president and council as to what action the society should take, but simply to state the reasons for and against the several suggestions put forward in the correspondence above mentioned.

The committee after prolonged investigation and consideration made a report of the desired character, stating incidentally its opinion that under the charters of the society the studies in question could, if it were deemed desirable, be taken charge of by the society itself.

The report of the committee was discussed at a special meeting of the Fellows, and the president and council, after carefully considering the report and the discussion at the above meeting of Fellows, adopted a resolution to the effect that they were of opinion that the studies in question ought to be taken care of by some academic organisation, and that this should be effected, not by the Royal Society taking charge of these studies, but by the establishment of some other body.

The president and council believe that the proposed academy, for which a petition has been presented, may with confidence be expected to take care of and promote the studies in question efficiently and successfully. They have reason to think that the establishment of an academy taking charge of such studies will be welcomed by all the constituent academies of the association, and they are prepared to offer it if established the cordial and friendly support of the Royal Society.

They therefore respectfully urge that the petition be granted.

And your petitioners will ever pray.

NOTES.

THE Croonian lecture of the Royal Society will be delivered on Thursday, March 13, by Prof. A. Gamgee, F.R.S., on the physico-chemical properties of hæmoglobin, its compounds and derivatives.

THE seventy-second annual meeting of the British Association will be held at Belfast on September 10–17, under the presidency of Prof. James Dewar, F.R.S. The presidents of the sections will be as follows:—A (mathematical and physical science), Prof. J. Purser; chairman of department for astronomy and cosmical physics, Prof. A. Schuster, F.R.S.; B (chemistry), Prof. E. Divers, F.R.S.; C (geology), Lieut.-General C. A. McMahon, F.R.S.; D (zoology), Prof. G. B. Howes, F.R.S.; E (geography), Colonel Sir T. H. Holdich, K.C.B.; F (economic science and statistics), Dr. E. Cannan; G (engineering), Prof. J. Perry, F.R.S.; H (anthropology), Prof. A. C. Haddon, F.R.S.; I (physiology), Prof. W. D. Halliburton, F.R.S.; K (botany), Prof. J. Reynolds Green, F.R.S.; L (educational science), Prof. Henry E. Armstrong, F.R.S. The evening discourse on September 12 will be delivered by Prof. J. J. Thomson, F.R.S., on "Becquerel Rays and Radio-activity"; and the discourse on September 15 will be on "Inheritance," by Prof. W. F. R. Weldon, F.R.S. The lecture to the operative classes, on September 13, will be by Prof. L. C. Miall, F.R.S, on "Gnats and Mosquitoes."

M. BAILLAUD has been elected a correspondant of the section of astronomy of the Paris Academy of Sciences in succession to the late M. Souillart.

ONE of Prof. J. C. Ewart's zebra-pony hybrids will be exhibited next week, March 13 and 14, in the Agricultural Hall, Islington.

THE Right Hon. R. W. Hanbury, M.P., President of the Board of Agriculture, has appointed a departmental committee to inquire into and report as to the present position and future prospects of forestry and the planting and management of woodlands in Great Britain, and to consider whether any measures might with advantage be taken, either by the provision of further educational facilities or otherwise, for their promotion and encouragement. The committee consists of Mr. R. C. Munro-Ferguson, M.P. (chairman), Sir John F. L. Rolleston, M.P., Mr. E. S. Howard, C.B., Prof. W. Schlich, C.I.E., Colonel F. Bailey, R.E., Prof. J. R. Campbell, Mr. J. H. Lewis, M.P., Mr. George Marshall and Dr. W. Somerville.

MR. R. H. TIDDEMAN, M.A., F.G.S., who joined the staff of the Geological Survey, under Murchison, in 1864, has just retired from the public service.

A MEETING of the Engineering Standards Committee was held at the Institution of Civil Engineers on March 4, to hear evidence on the question of the standardisation of locomotives and the specifications for the materials used in their construction. The questions down for consideration were:—(1) Is it desirable to proceed with the standardisation of locomotives? (2) If so, should this be a question of general design or only of component parts? (3) How far would it be of practical value to have standard specifications defining the quality of the materials used in locomotive construction?

ON Tuesday next, March 11, Prof. E. B. Poulton, F.R.S., will deliver the first of a course of two lectures at the Royal Institution, on "Recent Researches on Protective Resemblance, Warning Colours and Mimicry in Insects." The Friday evening discourse on March 14 will be delivered by Prof. Silvanus P. Thompson, his subject being "Magnetism in Transitu"; the succeeding discourse on March 21 will be given (in English) by Geheimrath Prof. Otto N. Witt, of Berlin, on "Recent Developments in Colouring Matters."

THE annual dinner of the Royal School of Mines was held at the Hotel Cecil on Friday last, Mr. Bedford McNeill being in the chair. In proposing "The Mining and Metallurgical Industries," the chairman alluded to the magnitude of the two industries connected with their profession, and said that mining in the past had been largely carried on by men who did not have the advantage of educational facilities, who had to learn largely, if not solely, in the school of experience. In spite of the improvement which had been effected in Cornwall, it had to be admitted that the conditions of practical mining in Cornwall were not fully representative of those higher developments which had been achieved in our colonies and in foreign countries. Mr.

W. Whitwell, in responding, spoke of the severe competition which the iron trade was experiencing in America, and attributed the success of the American iron trade in a great degree to the opportunities afforded in that country for education.

A FEW of the items in the Civil Service Estimates for the year ending March 31, 1903, are of interest in their connection with science and education. In the class of Salaries and Expenses of Civil Departments, the estimate for the Board of Agriculture, England, is 5378*l.* less than last year, but the Department of Agriculture, Ireland, has an estimate increased by 17,439*l.*, of which 4110*l.* is required for salaries and wages in connection with institutions of science and art, 300*l.* for the Royal College of Science for the purchase of books, specimens, &c., 1000*l.* for annual grants for science instruction, and 5800*l.* for grants in aid of day secondary schools. In the class of Education, Science and Art, there is a net increase of 235,446*l.*, of which extra amount the Board of Education will receive 170,884*l.*, while scientific investigation, &c., will obtain a net increase of 15,242*l.* The latter estimate includes an additional grant of 3000*l.* towards the cost of adapting and equipping Bushy House for the purpose of the National Physical Laboratory, this amount completing a total grant of 19,000*l.* There is also a grant of 16,000*l.* as the first instalment on account of a total sum of 42,000*l.* estimated to be required in a period of three years in connection with the international scheme for investigating problems connected with the fisheries of the North Sea and adjacent waters.

To celebrate the election of M. Bouquet de la Grye to the presidency of the Paris Academy of Sciences, the Artistic Union of Auvergne has had a medal designed and struck, and it was presented to him with an album containing expressions of esteem at a banquet held on February 13. The face and back of the medal are illustrated in *La Nature*, and the views are here reproduced. Colonel Laussedat presided at the banquet and referred in appropriate terms to the numerous scientific investigations of his colleague, from his first work in hydrography and on the transit of Venus expedition to his researches on the influence of the moon and his great scheme for making Paris a seaport. In reply, M. Bouquet de la Grye expressed himself conscious of the honour done him by the Academy of Sciences, and gratified at the celebration of it by his friends.

Medal presented to M. Bouquet de la Grye.

THE three very interesting papers on electric shocks which were read before the Institution of Electrical Engineers last Thursday direct attention to a subject of which very little seems to be known from either the electrical or the physiological side. Mr. Aspinall quoted a number of cases in which death might have been expected, but did not occur, and formulated a list of pertinent questions to which definite and certain answers would be of the highest value. Mr. Trotter gave a practical demonstration that the liability to shock at 500 volts is very much less than is generally believed. With dry boots and clothes he showed that one could quite safely stand or lie on an earthed rail whilst handling a live conductor at 500 volts. In other words, it is quite safe to fall across the rails of, say, the Central London Railway provided bare skin does not touch *both* the earthed and the live rail. Unfortunately, in a case of accident one cannot arrange the conditions for safety, and, moreover, a sudden unexpected shock may have much worse effects than one taken carefully and deliberately. The discussion of the papers on March 13 is likely to be of great interest. What is, perhaps, most desirable is that some definite information should be forthcoming on how best to restore life in a case of apparent death from electric shock.

AN interesting account of the electrical manufacture of carbon bisulphide is given in a recent number of the New York *Electrical Review*. The furnaces consist of tall stacks which are filled with charcoal; sulphur is fed in at the bottom of the furnace and allowed to rise, when molten, as high up the electrodes as is considered advisable. The molten sulphur acting as an insulator, the height to which it rises serves to regulate the current. Carbon bisulphide vapour is led off at the top of the furnace. The plant consists of two furnaces, each having a capacity of 20,000 pounds per day. One furnace lies idle, for cleaning, &c., whilst the other is running; it is said that a furnace can be run continuously for several months. The power is derived from alternators direct-coupled to water wheels, and at present only half the available water-head is being utilised. The larger output obtainable when the full water-head is used is likely to be considerably in excess of the demand.

WE have received an attractive pamphlet from the Acheson Graphite Company (Niagara Falls), which contains some useful information and data relating to the electrodes which they manu-

facture. The electrodes are first made up in amorphous carbon, which is then converted to graphite by baking at a very high temperature in the electric furnace. It is claimed that the conversion to graphite is complete. These electrodes are especially suitable for electrolytic purposes on account of their high conductivity and low porosity, and also, a recommendation which will appeal to experimentalists, on account of the ease with which they can be machined and worked. It is also not unlikely that the use of graphite electrodes in metallurgical processes will extend. Both in metallurgical and electrochemical work the quality of the electrodes is of the first importance, making in many instances all the difference between success and failure.

DR. C. JENSEN, of Hamburg, has contributed to the *Meteorologische Zeitschrift* for December last an interesting paper on the subject of atmospheric polarisation. The author reviews all the principal theories and discoveries from those of Arago in 1809 to the recent important works of Dr. Pernter relating to the analogy of various turbid media with the blue light of the sky. The author considers that the observation of atmospheric polarisation should be of use in weather prediction, as showing approaching cloudiness some hours before it is visible by other means, and also as showing whether the sky is clear or otherwise above a stratum of fog.

THE "campylograph" invented by Père Marc Dechevrens for mechanically describing certain ornamental curves is the subject of a paper by its inventor in *Cosmos* for February 22, and of a pamphlet, published in Brussels, by Père Potron, who deals with the equations of the curves it describes. The machine, to which the name campylograph is given, is an arrangement for compounding the projections, in two mutually perpendicular directions, of two circular motions, and as such it can be made to trace Lissajou's curves exactly, the amplitude of the component vibrations remaining constant instead of decaying as is the case with compound pendulums. Moreover, the table carrying the paper can be rotated and a variety of figures thus obtained, including the epicycloids and hypocycloids, and also curves similar to those given by a harmonograph with clockwork table, but without the gradual decrease in amplitude. It should, however, be remembered that numerous machines have at different times been designed for drawing various classes of ornamental curves, and it seems as likely as not that something practically identical with the "campylograph" may have been previously constructed.

SEVERAL papers tending to raise doubts regarding the well-known laws of electromagnetism for bodies in motion have already been noticed in these columns. M. R. Blondlot writes on this matter in the *Journal de Physique* for January. If a current of air is moving parallel to the axis of z in a magnetic field the lines of force of which are parallel to the axis of x, then, according to Hertz and Lorentz, an electromotive force ought to be set up in the negative direction of the axis of y, and if the two plates of a condenser are placed perpendicularly to this direction and connected by a wire so as to bring them to the same potential, they ought to become charged and to remain charged when they are separated. According to M. Blondlot, however, the only observable effects are such as can be accounted for by accidental causes, and are small in comparison with those required by theory. The author further remarks that by an application of the principle of action and reaction it would appear to follow that a displacement current in air exerts no magnetic action, and according to this view the discharge of a condenser is magnetically an open current. Or if this contradiction of Maxwell's theory be not admitted, we should have to abandon the principle of reaction.

THE spark spectra of those elements which are gaseous at ordinary temperatures have been extensively investigated, but little research has been hitherto done on the arc spectra of gases. Mr. O. H. Basquin has recently published, in the *Proceedings* of the American Academy of Arts and Sciences (vol. xxxvii pp. 161–174), an account of his research on "The Arc Spectrum of Hydrogen." In his apparatus, one electrode was made to rotate quickly, this preventing the welding together of the electrodes and also throwing the hot gases to one side. That part of the flame of the arc thus separated from the poles was very free from continuous spectrum, and he was thus better able to study the spectrum lines than if a stationary arc were used. The arc was enclosed in a comparatively air-tight brass "hood," through which a stream of electrolytically-prepared hydrogen was continually passing. The light from the arc passes through a lens fixed at the end of a brass tube fitting into the wall of the hood. The arc spectra in hydrogen of aluminium, copper, magnesium, coin-silver, sodium, tin and zinc were examined both visually and photographically. Of the well-known series of hydrogen lines seen in its low-pressure spark spectrum and in the spectra of the hotter stars, $H\alpha$ and $H\beta$ are well shown visually in the case of all metals except Na; the majority also show $H\gamma$, but $H\delta$ is rarely seen. $H\alpha$ is sharp and well defined, the others broad and hazy. In the photographic spectra, $H\beta$ and $H\gamma$ are seen in the case of all metals except Na, while $H\delta$ shows in the spectra of tin, silver and copper. A small dispersion spectrum of tin shows $H\epsilon$ also. The weaker hydrogen lines more refrangible than $H\epsilon$ have not been traced, this being probably due to the inordinate width of the lines, those detected averaging about twenty-five tenth metres. All the metals except tin give a characteristic set of lines which do not occur in the arc spectrum in air of the corresponding metal. These new lines do not seem to bear any particular relation to the spark lines of the respective metals, and the author supposes them to be due to compounds of hydrogen with the metals formed in the arc. No new lines have been found which can with certainty be attributed to hydrogen. At the end of the paper an interesting discussion is given of the general effects of the hydrogen atmosphere on the arc and its spectrum.

THE first of the international balloon ascents for the current year took place on January 9. At Chalais-Meudon the ascent was at 8h. a.m.; temperature at starting 1°.C., maximum height reached 11,405 m., minimum temperature −63°·1. At Trappes two ascents were made; the heights reached were 15,000 m., temperature −61°·4, and 15,670 m., −62°·2. At Strassburg a height of 8100 m. was reached; temperature at starting −4°.4, minimum −42°·8. One of the manned balloons at Berlin remained up for nearly twenty-nine hours, and the following readings were taken:—at starting, 3°·9; at 3490 m., −4°·3; at 4850 m., −15°·1. While travelling eastward the same stratum of cloud was always observed, the upper edge of which continually increased in height. Above the cloud an inversion of temperature occurred and a sudden change of wind from west to about north-west. Three balloons ascended from Vienna; in one of the manned balloons a temperature of −10° was recorded at 4100 m. Ascents were also made from Pavlovsk (St. Petersburg) and Mr. Rotch's observatory, Blue Hill, in the United States. Except at St. Petersburg, the balloons ascended in an extensive area of high barometric pressure, the centre of which lay over the Alps.

IN *Symons's Meteorological Magazine* for February, a map is given showing the places, so far as at present ascertained, at which deposits of yellowish-pink dust were observed on January 22 and 23. It attracted attention over practically the whole of Cornwall, near the western border of Devon, and at a few points in Somerset, the south of Gloucester and Glamorgan.

Specimens of the dust have been microscopically examined by competent authorities, and it appears to be of the same nature as that which is often carried over from Africa to Europe. Further particulars are needed for the purpose of a more detailed account. Dr. H. R. Mill gives some particulars respecting the high barometer readings of January last. The highest pressure before recorded in the British Isles was 31·108 inches, at Ochtertyre, on January 9, 1896, but the reading at Aberdeen on January 31, namely 31·11 inches, as given in the *Daily Weather Report*, was apparently a trifle higher than the previous record. Dr. Mill directs attention to the fact that the popular belief that a high barometer involves calm weather was somewhat rudely shaken by the easterly gale which raged in the Channel from January 31 to February 2—under the influence of the low-pressure area in southern Europe.

THE September issue (vol. vi. art. 1) of the *Bulletin* of the Illinois State Laboratory contains the first part of a history of the dragon-flies of that State by Messrs. Needham and Hart. The authors state that these insects, together with their near relatives the May-flies, are the isolated remains of an extremely primitive group, the members of which have become specialised along certain lines.

WE have received from the author, Mr. F. Finn, a copy of an interesting paper on the cage-birds of Calcutta, which appeared in the *Ibis* for July last. The taste for keeping birds in confinement has been prevalent for centuries among the natives of India, although now somewhat on the decline, the author citing evidence to show than an Australian cockatoo was imported in the time of Jehangir. It is satisfactory to learn that, on the whole, the treatment of these cage-birds is good. The natives display especial capacity for keeping soft-billed insectivorous species in confinement; and as an instance of the interest taken in birds, the author mentions that when a living bird-of-paradise was for the first time received in Calcutta, the then Amir sent a special messenger all the way from Cabul to ascertain whether it was really the bird he knew so well by report.

IN the course of a description of a new "agricultural ant" of the genus Pogonomyrmex, published in the *American Naturalist* for February, Prof. W. M. Wheeler takes occasion to dispose, once and for all, of the myth that certain ants of this group sow and reap the so-called "ant-rice." If the nests of the species in question be observed at the proper season, it will be seen that the workers often carry out from the store-chamber grains of ant-rice which have sprouted to deposit them in a heap some distance off. These seeds frequently, of course, take root and grow, and since the ants feed mainly upon such grass-seed, it is no matter for surprise that "ant-rice" should predominate in the ring of vegetation surrounding the nest. To state, however, that the ant, "like a provident farmer, sows this cereal and guards and weeds it for the sake of garnering its grain is as absurd as to say that the cook is planting and maintaining an orchard when some of the peach-stones she has thrown into the yard chance to grow into peach-trees." The myth will, however, probably be hard to kill, since it is supported, not only by the authority of Darwin, but is repeated in Lord Avebury's well-known work on ants.

THE oviparous species of peripatus form the subject of a long article (illustrated with a coloured plate) by Dr. A. Dendy in the February number of the *Quarterly Journal of Microscopical Science*. The fact that an Australian species of peripatus (using this term in a general sense) lays eggs was announced by Dr. Dendy in NATURE of February 14, 1889; and although, largely owing to some confusion in the identification of species, the statement was received with considerable scepticism, the author has now been enabled, not only to fully demonstrate its truth, but to show that the phenomenon occurs in a second Australian species. It is certainly a very remarkable circumstance that while the other known species of these primitive arthropods are viviparous, these two forms (now designated Oöperipatus) should lay eggs; and it would be of the greatest interest could the reason for the departure from the general rule be accounted for. Dr. Dendy, after describing the anatomy of the egg-laying species in considerable detail, discusses the phylogeny of the whole group.

TO the same journal Messrs. Bradford and Plimmer communicate an important paper on the organism infesting the blood of animals suffering from tsetse-disease. This parasite, for which the authors have proposed the name *Trypanosoma brucei*, is fully described and its life-history sketched. Many experiments have been made with the view of discovering whether any animals are immune against this parasite, but so far without success. The authors add, however, that there is probably in all animals some attempt at resistance to its attacks, and that this is effected by means of phagocytes. The parasite is closely allied to one affecting sewer-rats, which belongs to the same genus. The rat Trypanosoma does not, however, in the least protect the animal containing it against the tsetse parasite. It may be added that a beautiful series of greatly enlarged models illustrating the life-history of the latter is now exhibited in the Natural History Museum.

IN the last *Bollettino* of the Italian Seismological Society (vol. vii. No. 5), Dr. Cancani describes an interesting series of earthquakes felt during April and May, 1901, in the district round Palombara Sabina, near Rome, the strongest of which (on April 24) caused some damage to buildings. The focus of this earthquake being evidently at a very slight depth, Dr. Cancani ascribes the shocks to readjustments of the superficial strata due to the erosion of the underlying rock. From records obtained at Rome, Padua and Casamicciola, the mean velocity of the earth-waves was found to be 4·85 km. per second.

THE *Journal of Geography*, a new American monthly, succeeds the *Journal of School Geography* and the *Bulletin* of the American Bureau of Geography. The January number contains a paper on useful products of the century plants, by W. B. Marshall, and the first instalments of papers on field work in physical geography, by Prof. W. M. Davis, and on the trade and industries of western South America, by Emory R. Johnson. A special feature is "Geography Current," a series of notes and reviews on subjects bearing on various branches of geography.

THE *Journal* of the Society of Arts for February 14 contains a valuable paper by Commander R. Whitehouse, R.N., on the Uganda Railway and the survey of Lake Victoria Nyanza. On the opening of the whole line, the journey from Mombasa to Port Florence will take two and a half days, and the steamer journey from Port Florence to Mengo another day, as against seventy days by caravan. The railway has already opened up a large amount of country, and until other railways are constructed it must command the trade of the whole of that part of Central Africa.

THE Berlin Gesellschaft für Erdkunde begins the year with a change in the form of its publications. The *Zeitschrift* and the *Verhandlungen* are now combined in a single journal, which retains the name of the former, and is to appear ten times a year. The January number contains, among other things, papers by Herr O. Neumann, on a journey from the Somali coast through southern Ethiopia to the Soudan, by Herr K. Sapper, on the physical geography of Honduras, by MM. E. Reclus and Valère Maes, on the "disque globulaire" (the

admirable maps on natural curvature produced recently under M. Reclus' direction), and a report by Dr. E. von Drygalski, dated Cape Town, on the progress of the German South Polar Expedition.

THE Queensland Geological Survey, under the direction of Mr. William H. Rands, has forwarded *Bulletins* Nos. 13 to 17 (1901). In these we have additional notes on the Cretaceous fossils of Queensland by Mr. Robert Etheridge, jun., and reports on mining districts by Mr. Rands and Mr. B. Dunstan. Referring to the Mount Morgan mine, Mr. Dunstan remarks that it is impossible to tell by appearances whether the stone is rich or poor, as of two samples which might be absolutely the same in texture, colour, structure, specific gravity and visible mineral constituents, one would perhaps yield as many ounces of gold to the ton as the other would pennyweights. In an account of Diglum Creek, in the Gladstone district, Mr. Dunstan describes the production of garnet, wollastonite, epidote and chert where granite has come in contact with limestone. We have also received folio reports on the Gympie gold field by Mr. Rands, and on the Hamilton, Coen and Jordan Creek gold fields by Mr. Lionel C. Ball. Permo-Carboniferous coal-bearing beds occur in the valleys of the Dawson and Mackenzie rivers, and outcrops of anthracitic coal have been traced by Mr. Dunstan. The Dawson coal, which is a ten-foot seam, is reported to be suitable for general purposes and as absolutely smokeless. In central Queensland there is an area of upwards of 5000 square miles which may be coal-bearing; hence a closer and more detailed examination of this region is desirable.

MESSRS. CASSELL AND CO. have commenced the publication, in fortnightly parts, of "Familiar Wild Flowers," by Mr. F. E. Hulme The complete work contains 280 coloured pictures, including 40 which have been specially prepared for the new edition, and will be completed in twenty-four parts at sixpence each.

MR. W. WESLEY, of Essex Street, Strand, sends us a "Catalogue of Zoological Literature" (No. 140, in two parts). As it includes the late Mr. S. P. Hanley's conchological library, as well as the entomological library of Mr. H. Christoph and the works on Cœlentera collected by the late Prof. G. J. Allmann, it is worth careful attention on the part of those interested in such subjects.

MORE than forty years after his first determinations of the transport numbers of the ions in the passage of electricity through solutions of electrolytes, W. Hittorf describes, in the *Zeitschrift für physikalische Chemie*, some interesting experiments relating to the influence, exercised by the diaphragms separating the anode and kathode solutions, on the measured values of these transport numbers. When a porous clay diaphragm is used, the volume of the solution at the anode decreases in all cases investigated. When, however, an animal membrane separates the anode and kathode solutions, it is found that with solutions of the chlorides of potassium, ammonium and sodium, cataphoresis takes place in the direction of the current, whilst with dissolved chlorides of the alkaline earth metals and of cadmium, the cataphoric effect is in the opposite direction. In the latter case, the volume of the solution at the anode increases. At the animal membrane, apparently a separation of the original solution into a solution more concentrated and one more dilute takes place. This behaviour of animal membranes results in considerable errors in the determination of transport numbers, and Hittorf is able to account for the deviations between the results obtained by himself in the late fifties and those more recently obtained by other investigators who have not made use of animal membranes in their experiments.

THE additions to the Zoological Society's Gardens during the past week include a Pluto Monkey (*Cercopithecus leucampyx*, ♂) from Uganda, a Leopard Tortoise (*Testudo pardalis*) from British East Africa, presented by Major C. Delmé Radcliffe a Vulpine Phalanger (*Trichosurus vulpecula*) from Australia, presented by Mr. T. W. Dye; three Bengal Red-vented Bulbuls (*Pycnonotus bengalensis*) from India, presented by Mr. Frank Finn; a Ludio Monkey (*Cercopithecus ludio*) from West Africa, two young Lions (*Felis leo*, ♂ ♀) from British East Africa, four Prjevalsky's Horses (*Equus prjevalski*, ♂ ♂, ♀ ♀) from Mongolia, a Red Lory (*Eos rubra*) from Moluccas, a Green Conure (*Conurus leucopthalmus*) from Trinidad, an Angulated Tortoise (*Testudo angulata*) from South Africa, deposited; an English Wild Cow (*Bos taurus*) born in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE SPECTRUM OF THE CHROMOSPHERE.—At the recent meeting of the Astronomical and Astrophysical Society of America, held at Washington, Mr. S. A. Mitchell read a paper on the observations made during the total solar eclipse in Sumatra on May 18, 1901. The spectrum photographs were obtained with an objective grating spectrograph; the grating had a ruled surface $3\frac{1}{2} \times 5$ inches, with 15,000 lines to the inch, the objective being a quartz lens of a little more than $3\frac{1}{4}$ inches aperture and about 72 inches focal length. Light from the eclipsed sun was reflected into this instrument by a cœlostat. The adjustments were such as to ensure a "normal" spectrum, this being the case when grating and photographic plate were each perpendicular to the diffracted beam. The first order was employed, from λ 3000 to λ 6000. Although the sky was never clear during the period of totality of 5 min. 41 secs., eight exposures were made—one before and one just after totality for the cusp spectra, one at first and one at second flash, and four with varying exposures during the total phase. The second flash appeared fully exposed, and the plate has been carefully measured. The dispersion is such that from $H\beta$ to $H\epsilon$ occupies a length of 95·4 mm., *i.e.* 1 tenth-metre corresponds to about 0·1 mm. In the region mentioned, $H\beta$ to $H\epsilon$, 363 lines have been determined. Of these, 269 have been identified with lines on Rowland's map.

Tables have been made of the ratios between the intensities of lines in this flash spectrum and in the ordinary Fraunhofer spectrum, and also of the ratios of the number of lines of each element identified to the whole number of solar lines for that metal. Both these sets of ratios appear to show systematic variation, and they are grouped into three classes, their behaviour being considered in conjunction with the atomic weights of the elements.

The variations in intensity are considered as chiefly due to the various heights to which the different metals ascend in the chromosphere. It is thought that the metals of group II. extend very high and are nowhere very condensed, and their flash lines will be true reversals of the corresponding solar lines. The metals of groups I. and III. are denser near the sun's surface and do not extend so high, and hence their flash lines are to be regarded as only partial reversals of the Fraunhofer lines. These facts lead the author to conclude with a renewal of faith in the existence of the "reversing layer."

PHOTOGRAPHIC DETERMINATION OF LONGITUDE.—In the *Comptes rendus*, vol. cxxxiv. pp. 387–389, M. G. Lippmann describes a new method for the photographic determination of longitude, using an apparatus originally designed by M. Fabry (*Bulletin Astronomique*, p. 148, 1895) for visual observation only. The arrangement was extended by M. Lippmann so as to permit of photographic registration, and described in *Comptes rendus*, cxxxiv. pp. 205–208. The principle of the method consists of making simultaneous records of the zenith at each station, the required longitude being the difference in right ascension observed. The apparatus is similar to that employed for nadir observations. Light from an adjustable horizontal collimator falls on a half-silvered mirror inclined at 45° to the vertical, and is reflected to the surface of a bath of mercury. After its reflection from the mercury, the light is again reflected from the mirror into the collimator, giving an image of the slit or cross-wires which may be adjusted to coincide with the source.

When this is done, a telescope is employed to photograph the region about the zenith as reflected from the upper surface of the silvered mirror. In this position the photographic telescope will lie in the same direction as the fixed collimator, and thus it can be arranged to have a suitable exposing screen, by which, at any instant, a short exposure is given to a strong light placed near the collimator slit, which will give an image of the slit superposed on the region near the zenith, the centre of this image indicating the instrumental zenith. All that remains to be done is to provide a duplicate apparatus at a second station, and by operating the exposing shutters of their respective collimators by electric means, the zenith of each place will be automatically recorded. The difference of longitude between the two stations will be equal to the difference of the right ascensions of the two collimator images. The chief corrections will be owing to the possible prismatic form of the reflecting mirror and the catalogue errors introduced in computing the right ascensions.

INDIAN SURVEYS.[1]

THE Report on Indian Surveys for the year 1899–1900 is now before the public, and the resolution of the Government of India which concludes this report pronounces it to be one which reflects great credit on the "able and effective administration" of Colonel St. G. Gore, R.E., the present Surveyor-General. Field operations were carried on by one double and fifteen ordinary parties and four detachments. Eight of these parties were employed on topographical (including geographical) surveys, only one on trigonometrical work, and the remainder included cadastral and traverse surveys and special geodetic investigations. A large area of forest survey was also completed. The total outturn amounted to nearly 150,000 square miles, of which more than 120,000 square miles were "reconnaissance" or geographical surveys, on the ¼-inch or smaller scales, in Burma and on the north-west frontier. The total area of rigorous surveys on all scales was 29,418 square miles. The normal scale for topographical surveys in India is 1 inch = 1 mile, and the cost of these surveys (which are based on rigid triangulation) is from 25 to 30 rupees per square mile—a cost which compares favourably with that of American surveys conducted under similar physical conditions, but with a very different staff of employés. The cheapness of Indian surveys is doubtless due to the general employment of skilled native labour. In this connection it is satisfactory to note that natives are now being instructed to triangulate and that the magnetic party which has been lately inaugurated will be placed under a native observer.

The general increase in the outturn on that of the previous year is due to the accession of an unusually large area of geographical mapping, full details of which are not published. Topography, conducted on rigorous methods, was chiefly confined to Burma and Sind, two countries which, whilst they balance each other geographically on the east and west, afford a useful contrast for comparison of cost rates and methods of survey. Of the special work undertaken by the Department, that which resulted in a comparison of the values of level deflection by means of observed latitudes on Great Arc stations receding gradually from the Himalaya is most instructive, and special attention is called by the Government of India to Captain Lenox Conyngham's discussion of the results obtained. Experiments were made with the Bridges-Lee photo-theodolite, and with the Jaderin base measuring apparatus which promises, if not to supersede the complicated adjustment of compensation bars altogether, at least to simplify the process of measuring bases for all but the most rigidly accurate geodetic purposes. The former is pronounced to be a very promising auxiliary to the plane table (especially in mountainous countries), "but it will never supersede it." This, it may be remarked, is nearly coincident with the opinion of Canadian surveyors who have tested photo-topography far more exhaustively than has been done in India. As regards the Jaderin apparatus, an unfortunate uncertainty about the value of the coefficients of expansion in the metals forming the tape has deferred an expression of opinion on its success or otherwise.

Record is made of a most useful invention in the printing office by a R.E. foreman which enables the process of photography to be eliminated from the cumbersome method of map reproduction by photo-zincography. There can be little doubt of the value of the invention, which is fully described, and which has been patented in India. It has already enabled the printing office to deal with a vast number of maps in excess of the normal outturn. We are glad to observe that the invention has met with prompt recognition by the Government of India. The report contains three or four excellent photogravure illustrations, one of which is a suggestive view of a railway bridge on the Mandalay-Kunlon line, which is now under construction.

The map illustration is perhaps the most unsatisfactory feature in the report. One map at the commencement of the volume purports to show the "progress of the Imperial surveys," and exhibits a special colour to denote "geographical reconnaissance on various scales." According to this map a large area of the Madras province has never even been "geographically reconnoitred"—which is a very astounding fact if it is true—for it is blank white paper. And the fact that no surveys are shown in Baluchistan must be due either to an affectation that British Baluchistan and Quetta have nothing to do with India, or else it is a deficiency in the illustration, for it leaves an enormous area of the outturn of the Department which is included in the body of the report absolutely unaccounted for. The triangulation chart adjoining shows a very satisfactory-looking series extending to Kandahar from the Indus, and another series reaching half way through Makrán. Triangulation usually carries topography on its back, and doubtless it does so in the present instance. Why the extent of transfrontier "geographical reconnaissance" (to say nothing of exact detailed topography) should not be shown in the chart it is difficult to imagine.

[1] General Report of the Operations of the Survey of India Department, 1899–1900.

MILROY LECTURES ON TYPHOID FEVER.

IN his second and third (final) lectures at the Royal College of Physicians, Prof. Corfield gave detailed descriptions of a number of outbreaks of typhoid fever which had been traced to specific contamination of drinking water, and exhibited a table which he had prepared demonstrating the fact that during the ten years 1891 to 1900 (with the exception of 1897) typhoid fever has been more prevalent in St. George's, Hanover Square, in November and December than in August, September and October, the months when it is normally prevalent, the average number of cases per month for November and December having been 7·2, and for August, September and October only 4·2. This excess of typhoid fever in November and December was coincident, he said, with the increase in organic matter in the water supplied by the Thames companies when the river was in flood. He pointed out that Mr. Shirley Murphy, the Medical Officer of Health of the London County Council, had drawn attention to the fact that in 1894 there was an excess of typhoid fever in November and December in the London districts supplied by all the water companies, except the East London and the Kent companies, and that this followed exceptional floods in the rivers Thames and Lea. Dr. Corfield stated that he was satisfied from these facts that the distribution of inefficiently filtered river water during November and December was the cause of the increase in the number of typhoid fever cases which occurred among persons especially liable to the disease.

Among the cases of polluted well water described by him, perhaps the most interesting and remarkable was one which he had recently investigated at a country house where there had been a case of typhoid fever, and where, by a peculiar arrangement of the suction pipes of a pump, water was, in certain circumstances, siphoned automatically from a pond polluted with the house sewage into the well supplying drinking water.

Dr. Corfield then described a number of outbreaks in which the poison of typhoid fever had been distributed by means of milk, oysters, cockles and mussels, ice-creams, ginger-beer, and even oranges and grapes, these fruits having been thrown, because they were decaying, into an ash-pit where typhoid excreta had been previously put, and having been picked up and eaten by a number of children.

Among the reports quoted were some from Belgium, France and Germany, kindly sent him by Dr. Kuborn, of Seraing-Liége, Dr. Brouardel, of Paris, and Dr. Pistor, of Berlin, respectively, and also some from different parts of the United States, and others by Dr. J. Ashburton Thompson, the President of the Board of Health of New South Wales.

In concluding his account of the communication of the disease

by foods, Dr. Corfield stated that in 1871 he was called on to inspect the house at which His Majesty (then Prince of Wales) was supposed to have contracted typhoid fever, and reported the results of his investigations in a letter which appeared in the *Times* of January 22, 1872, in which he showed that, although there were certain sanitary defects in the house in question, there were no such defects as had been previously described. For instance, it had been said that the water-closet in their Royal Highnesses suite of apartments was directly connected with a cesspool beneath them, and that its soil-pipe was not ventilated. Neither of these statements was true; there was no cesspool under the water-closet at all, nor, indeed, anywhere on the premises, and the soil-pipe was fully ventilated. There was, in fact, nothing the matter with that water-closet, and it is certain that His Royal Highness did not get his attack of fever from any foul air in it. There was, however, a defect in a water-closet in the middle of the house, and he was unable to say positively that the outbreak of the disease was not due to defective sanitary arrangements. On looking through his notes, made some thirty years ago, he had come to the conclusion that, although it was proved that the outbreak was not caused by water or milk, it was in all probability caused by some other food (such as oysters or salad) which was partaken of by His Royal Highness, the other gentlemen of the party and some of the menservants (among whom all the cases occurred), perhaps at a shooting luncheon, but not by the Princess of Wales, or by any of the other ladies or female servants. Had the outbreak been caused by the insanitary condition of the premises, it would certainly have attacked some of those who were most in the house, whereas it attacked those who were most out of doors and some of those who did not sleep in the house at all.

He then described cases in which the disease had been distributed by means of sewer air and by the washing and mangling of clothes. The questions of ground water and of direct infection were also considered. An account was given of the behaviour of the typhoid bacillus in various circumstances, and the lecture concluded with a reference to the prevalence of typhoid fever in South Africa and its probable dissemination by means of dust and flies, as well as by water, and with some tables of statistics showing the great diminution of the death-rate from the disease in England and Wales, and also in Paris, during recent years. The increase of the disease in Paris during the years 1899-1900 was not peculiar to that city, as it was shared by London and England generally, and it was only heard of because the Paris Exhibition was held in 1900.

EVOLUTION AND ITS TEACHING.[1]

EVER since the dawn of the human intellect, man has tried to increase his knowledge in two ways, by observation and by speculation. Observation came first, for that is common to man and animals. Speculation is a distinctly human attribute, and we find that it soon out-distanced observation, and formed the basis of the earlier philosophies. But during the last few centuries, the observational method has once more come to the front under the name of science, and its conclusions have not always been in accord with those of the speculative philosophies which preceded it.

The difference between the two methods is that whereas speculation starts a chain of reasoning from one or two propositions which are taken as absolutely true, science reasons from the basis of as large a number of observations as possible, and tries to find a hypothesis which connects them all together; or explains them, as it is usually called.

An Outline of Evolution.

The idea of evolution originated with the Greeks, but only as a speculation, which led to nothing; and its scientific history may be said to commence in the early part of the last century, when the practically new theory of the origin of species by gradual development was proposed by Lamarck. This theory was at first discredited for lack of evidence; but it was developed and demonstrated by Darwin in the middle of last century. About the same time it was pointed out by Lord Kelvin that not only was the sun cooling, but that all kinds of energy, when converted into heat, lost a portion by radiation into space, and that this process must go on until the whole universe was of a uniform temperature. So that, although the amount of energy in the universe remains unalterable, it will, by redistribution, be brought into the potential state, and thus, when every possible action is counterbalanced by other actions, energy will practically disappear.

From this theory of "dissipation of energy" it follows that as the earth is cooling, life cannot go on for ever; and also that at some former time the earth must have been too hot for the existence of protoplasm. Consequently, life can only have a limited existence on the earth. It must have had a beginning, and must come to an end.

But the inference extended further. Not only living beings, but even the whole solar system must have had a beginning, not indefinitely remote; because most of its members still contain a large amount of their original heat. And if the solar system had a beginning, so also must each star in the heavens have had a beginning; for the very fact that we can see them is a proof that they are radiating out energy. And, it was asked, why should not the whole universe, visible and invisible, have had a common origin and a common beginning in time? This had been the opinion of Immanuel Kant in the middle of the eighteenth century, and although modern astronomy has not altogether confirmed his speculations, it has proposed a hypothesis which is not very dissimilar. This is the "meteoritic hypothesis," and is chiefly the work of Sir Norman Lockyer and Prof. G. H. Darwin. I will give you a short sketch of the views held by the former.[1]

Inorganic Evolution.

The close connection between the orbits of comets and those of meteoritic streams has led to the universally admitted conclusion that comets are neither more nor less than swarms of meteorites. Again, the resemblance between the spectra of comets and those of nebulæ suggests that these also are swarms, or aggregations, of meteorites. And we naturally infer that the stars with similar bright-line spectra must be collections of meteorites. From bright-line stars we pass to those of which the meteoritic origin is no longer to be recognised, all having blended together. Further, it is claimed that by supposing variable and temporary stars to be due to the meeting and entanglement of two meteoritic swarms we get a better explanation of the observed phenomena than any other hypothesis can give.

This meteoritic hypothesis supposes that the present material universe was at one time in a state of "cosmic dust," spread irregularly through space, and moving slowly in many directions. It is the original irregular distribution of the cosmic dust and its irregular movements which are the source of all the energy in the universe. We have specimens of this cosmic dust in the chondroi, or spherules, of which many of the stony meteorites are built up. They are small round bodies of crystallised minerals, varying from microscopic dimensions to the size of a marble. Of course, these chondroi are not the first form in which matter existed. They are evidently due to chemical reactions, and we could frame several different hypotheses as to their origin and history. But these would be speculations which could not, at present, be verified, and so we must content ourselves with the chondroi as the earliest form of matter known to us.

Through the action of gravitation, much of the cosmic dust is supposed to have aggregated into meteorites, the irregular movements of which were, in certain places, reduced to order; and so arose a number of meteoritic streams, or swarms, moving through space. Still, under the force of gravitation, each of these swarms got more and more dense, until, at last, collisions took place between the meteorites; light and heat were given out, and the swarm became a nebula. The heat produced by the collisions would, at first, be slight, but would gradually increase, until the whole of the solid material was resolved into vapour and a star was formed. Concentration, however, would still go on, and the temperature of the star would rise until, in time, the loss by radiation more than counterbalanced the gain by concentration, when the star would begin to cool. At last light would no longer be given off, and the star would end by becoming a dark cold body moving in space. Of course, some stars would attain a higher maximum temperature than others, and either a single or a double star might be the result of the condensation; but all would follow a somewhat similar development.

[1] Abridged from an inaugural address, delivered before the Australasian Association for the Advancement of Science, by Captain F. W. Hutton, F.R.S., president, on January 8.

[1] See "The Meteoritic Hypothesis" (Macmillan, 1890); and "Inorganic Evolution" (Macmillan, 1900).

Now, as a matter of fact, the spectroscope shows us that stars in all these stages actually exist at the present day in the heavens. In some the temperature is increasing, in others it is decreasing, and, although small stars must run through their development quicker than large ones, this is quite insufficient to account for all the present differences. From which it follows that some of the stars are much older than others. The sun was amongst the earliest of formed stars. When it was born, the sky must have presented an almost uniform blackness. There was no Milky-Way; no Orion or Southern Cross; no Pleiades or Dog Star. All these, and many others, have been added since; not altogether, but one after the other, through the long ages during which the sun was undergoing development. Judging by the relative ages of the stars, it seems probable that the process of concentration of the original cosmic dust commenced near the solar system and spread outwards to the Milky-Way. But, however this may be, the process is not yet over. Many nebulæ have not yet condensed into stars. Swarms of meteorites still traverse space, and, even in the neighbourhood of the solar system, they are so abundant that the earth alone is estimated to collect more than twenty millions each day.

However, slow as the process of condensation is, it is not endless. In time all the meteoritic dust will be collected into stars or planets, and in time the law of dissipation of energy will bring all these bodies to a uniform temperature. So at last the movements due to the original unequal distribution of matter will cease and the life of the universe will come to an end. We know of no process of rejuvenescence by means of which dissipation of energy, and the force of gravitation, might be counteracted. Several attempts have been made to refute the theory of dissipation of energy, but all have failed. The ether which pervades space is the only part of the universe which shows no sign of evolution. It alone remains unchanged.

A casual glance at the stars gives us the impression of immutability. We still speak of the fixed stars in much the same way as our forefathers used to speak of the everlasting hills. But we know that they are not fixed. We know that the nearer stars, including the sun itself, are in swift movement; and we infer that all are so. But we can see no connection between their movements. Single stars, or small groups of stars, are rushing through space in various directions, and we cannot detect any common centre of gravity which holds them in control. The stars have not yet attained the regularity of movement that gravitation must bring about in a very ancient system, and this idea of the comparative youth of the universe is strengthened when we remember that large numbers of the primitive meteorites are still wandering in space uncondensed into stars. If it be true that the sun is one of the oldest stars in the universe, and if, as geologists think, the earth is not more than a hundred millions of years old, then it may very well be that the creation of the cosmic dust out of which the stellar universe has been formed took place less than two hundred millions of years ago. But although it may be possible to place a limit to the age of the universe, we can fix no time for its duration. It is impossible to form an estimate of the hundreds of millions of years that will pass before the end approaches. Still, a time must come when all energy will be equilibrated, and when, possibly, the visible universe may resolve itself into invisible, motionless ether.

In the solar system we can study the development of a meteoritic swarm in greater detail. Here we find that the whole of the meteorites did not collect into a single mass, but that several planets, as well as the sun, were formed simultaneously. It has been shown by Prof. G. H. Darwin that the effect of many collisions among a swarm of meteorites would be gradually to eliminate orbits of great eccentricity until, in time, a regular system would be developed, when the whole of the meteorites would travel nearly in the mean plane of their aggregate motions. The larger of the meteorites would tend to settle towards the centre, while other aggregations might easily occur at different distances from the centre. And of these the outer planets would be larger than the inner ones, because in the more distant regions, where the attraction of the central sun was less, the movements of the meteorites would be slower, and there would be a greater tendency to agglomeration than where the movements were more rapid. As meteorites contain but little oxygen, hydrogen, carbon, silicon and alkalis—substances which are all abundant on the surface of the earth—large numbers must have been fused together to form the earth, and the lighter substances must have collected near the surface. Consequently, the collisions between these meteorites must have occurred with sufficient rapidity to melt the whole mass. For after a solid crust had been formed, all the meteorites which fell on the earth would remain on the surface as they do now.

As with the solar system, so, also, in the earth itself we can trace distinctly a physical evolution. The discovery of tidal friction gave an independent proof that the earth had had a beginning not infinitely remote, for if that had been the case, the tidal friction would have reduced the time of the earth's rotation on its axis to that of the moon. Also we have sufficient geological evidence to show that not more than one hundred millions of years ago the earth was in a molten condition, and, probably, shone with its own light. As cooling went on, the silicates crystallised out, forming a solid crust over the still molten, metallic interior, the earth then becoming a dark body. At that time all the water above the crust was in a state of vapour which, subsequently, fell as hot rain, forming a boiling ocean. With this rain the denudation of the primitive crystalline rocks commenced, and their débris was deposited on the bed of the ocean as sedimentary rocks. Gradually the continents were formed, the new ranges of mountains following each other in orderly succession, the great oceans becoming narrower and deeper as well as more and more salt. These processes are still going on, but, as the earth is cooling, the internal energy which uplifts the mountains must be diminishing, and in time it will be insufficient to counteract the denudation. Then the whole of the land will be swept into the sea, and the waves of the ocean will roll over the surface of the earth unopposed; unless, indeed, before that time arrives the ocean should have been frozen into a mass of ice, or should have sunk slowly into the ground. All these things are approaching, but which of them will come first it is impossible to say.

Organic Evolution.

When, during the course of physical evolution, the ocean had become sufficiently cool for the existence of protoplasm, minute living organisms appeared on its surface. These increased in size, varied in many directions, and, in time, discovered the bottom of the sea, on which they established themselves, changing from swimming to crawling creatures. Gradually these organisms managed to live in safety among the rough waters of the sea coast, and then they spread over the land, first the plants and then the animals, which came to feed on the plants.

Once established on land and breathing air, improvements in the circulatory system of the higher animals became possible. The purified blood was kept separate from the impure blood, and increased rapidity of physiological processes heated the body, so that, in the birds and mammals, a stream of pure, warm blood was poured upon the brain. Thus stimulated, the brain developed rapidly, and the psychological evolution, thus inaugurated, has reached such a height in man as to place him mentally apart from the rest of the animal kingdom.

Biological evolution differs from physical evolution in being brought about by the transmission of bodily variations from one generation to another. And in psychological evolution, mind is transmitted from parent to offspring, as well as the organ in which it is to be manifested. Intelligence, however, depends, not only on the structure of this organ, but on early associations and education, by which means the wisdom of one generation is handed down to the next.

Psychological evolution consists of two parts. The first is intellectual, and is found in all the higher animals as well as in man. The second is ethical, and is exclusively human.

Intellectual evolution, like biological evolution, is due to competition between different individuals and the action of selection. We probably see the first germs of ethical evolution in parental affection, which, among gregarious animals of sufficient intelligence, widened into social sympathy, and this, in man, gave rise to the social or civic virtues.

This advance also appears to have been, or, at any rate, may have been, due to selection, and the result was the emergence of what is called utilitarian morality. Morality, in the strict sense of the term—that is, formal morality—also appears to have arisen from sympathy, but not by means of selection. The long and constant use by man of formal morality has made it instinctive, and has thus given rise to the conscience.

Secondary Causes.

When we think of the whole work that has been accomplished by evolution we are overwhelmed by its vastness. The results of organic evolution, particularly, are so marvellous that, to our

limited intelligence, the forces to which they are due seem to have been constantly directed in their course. The human mind is more disposed to accept the idea of guidance than that of predetermination, as it seems to us to be the less impossible of the two, and the more easy to understand. We ourselves wait upon circumstances; we see how things are going to shape before we move, and we fancy that the world must have been made, and must be carried on, on the same principle. But the study of nature gradually causes this belief to fade away. The more we learn the more we see that secondary law extends much further than we had expected, and we begin to think that all may be due to secondary laws.

We cannot doubt but that the most complicated cases of inheritance—such as the growth of the train feathers of a peacock, or the gorgeous wings of a butterfly—are due to secondary laws, although the processes are quite incomprehensible to us. We believe these to be due to secondary laws, because we see them taking place in exactly the same order over and over again; and in the case of the peacock we know that if we pull out the feathers, new ones, similar to the old, will replace them. So that we can bring these laws into play whenever we choose. It is not sufficient, therefore, to say that an action is not due to secondary law, because it is so wonderfully intricate, or because it is incomprehensible to us. We must be able to show, either that the action is antagonistic to known natural laws, or that the result could not be due to a combination of any natural laws that we have already discovered. That is, we must show a discontinuity in the phenomena. Can any such breaks be discovered?

The origin of the material universe, which was the starting point of the present evolutionary process, appears to us to have been a new departure in natural law. But we cannot feel certain about it, for we do not know, and never can know, what went before. But with the origin of life on the earth it is different. The intimate structure of organic beings, as well as their order of development on the earth, point to the conclusion that they are all derived from a common ancestor, and that living protoplasm was formed once, and once only, on the surface of the sea. Now, in the origin of living substance on this planet we have a case which is generally recognised as a break in continuity. It is generally allowed that it was an action which is not only incomprehensible by us, but one which conflicts with our knowledge of natural laws. That an unstable chemical compound, endowed with the power of directing energy independently of any outside agent, should have been brought into existence by the action of known physical laws is an impossibility. The processes of assimilation and fission, on which all progress depends, are quite distinct from anything which had gone before. And as every living cell is imbued with what we call instinct, which directs its energies, it follows that in physiology action and reaction are not equal and opposite. Indeed, every organism inherits from its parents a store of energy which directs growth and which appears to be inexhaustible. It is drawn upon during the whole period of growth, which, in some plants, lasts all through life, and yet abundance is left for transmission to its offspring, no matter how numerous they may be. The store increases instead of diminishes, and we cannot tell why. Until some explanation can be given, it is not only permissible, but reasonable, to view the origin of life as due to some guiding action of natural law, especially when we remember what that break in continuity has led to.

Again, it has been often pointed out that the genesis of consciousness is as great a mystery as the genesis of life, and that it seems to be equally opposed to the law of conservation of energy. In the lower animals, and in some of the lowest plants, we see physiological processes producing movements which appear to be intelligent, but which, in reality, are no more so than the movements of the leaves of a sensitive plant. And it is generally allowed that for the exhibition of consciousness a brain-cortex is required; but how matter in the brain-cortex becomes self-conscious we cannot understand. However, it is possible to suppose that mind is a necessary concomitant of life, so that the origin of the two may be one and the same problem. Also, as consciousness may be lost—as in habit—and regained by attention, it is possible that consciousness may be a constant function of mind, but one that cannot become efficient until a large number of specially formed cells are accumulated in a brain-cortex. I cannot, therefore, see that the genesis of consciousness in animals necessarily marks a break in continuity, notwithstanding that its origin is quite incomprehensible to us.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Proposals have been laid before the Senate for modifying the principles of classification in the natural sciences tripos, though the proposals are not unanimously acquiesced in by the boards concerned. In part i., in which at present the aggregate mark in three or four sciences governs the class, it is suggested that weight should also be given to the candidate's particular performances in each subject. In part ii., a candidate is required, for a first class, to take at least one primary and one subsidiary subject; it is proposed to abolish the requirement of a subsidiary subject. It is further proposed that human anatomy and vertebrate comparative anatomy should in future be reckoned as a single subject in this part of the tripos. These changes, if approved, are to come into effect in 1904.

Earl Spencer, K.G., has been appointed an elector to the professorship of agriculture in the place of the late Sir J. H. Gilbert, F.R.S.

UNDER the will of the late Dr. Nathaniel Rogers, the Senate of the University of London offer a prize of 100*l*., open for competition to all the members of the medical profession in the United Kingdom, for an essay on "The Production of Immunity in Specific Infective Diseases—generally, and with particular Reference to any one Disease on which the Writer of the Essay may have made Original Investigations." Essays must be sent in not later than February 28, 1903, addressed to Mr. Percy Wallace, secretary to the Senate.

THE report of the executive committee of the Carnegie Trust for the Universities of Scotland on the administration of the trust for the period from June 7, 1901, to December 31, 1901, was read and passed at a meeting of the trustees last week. For the winter session 1901–2, the sum of 22,941*l*. 16*s*. 6*d*. was paid by the trust up till December 31, 1901, on behalf of 2441 students, representing the fees of 7610 classes. The committee, in accordance with the expressed desire of Mr. Carnegie, did not make question respecting the circumstances of applicants; but from information voluntarily offered by applicants themselves, they have ample assurance that in a large number of cases the payment of class fees has proved a boon of the greatest value to deserving students, and many acknowledgments of the letter sent to the parents and guardians of applicants express gratitude for the timely assistance rendered by the Trust. The class fees paid and the number of students were as follows:—St. Andrews, 268 students, class fees, 2452*l*. 16*s*.; Glasgow, 828 students, class fees, 7672*l*. 13*s*. 6*d*.; Aberdeen, 473 students, class fees, 3806*l*. 1*s*. 6*d*.; Edinburgh, 872 students, class fees, 9010*l*. 5*s*. 6*d*.

MR. J. H. GARTSIDE has given to the Owens College, Manchester, the sum of 10,000*l*., which has been applied in the purchase of an annuity of 1163*l*. a year for ten years, payable to the college, to be used for the provision of scholarships, which are to be known as "The Gartside Scholarships of Commerce and Industries." The scholarships are intended to induce young men who have already received a good education to devote a year at least in Owens College to the special study of subjects bearing on commerce and industry, and then to go abroad for the study of some particular subject, either in Germany or the United States, or some other country approved by the electors to the scholarships. The emoluments of the scholar while in England will be about 80*l*. a year, but when travelling abroad a larger sum will be given, which in the case of scholars travelling in the United States will probably be about 250*l*. per annum. The scholars are to furnish reports of their investigations in the foreign countries which they visit. These scholarships are intended by Mr. Gartside to be an incentive and assistance to those who contemplate a careful study of commercial and industrial methods, and should enable useful information to be obtained with regard to these subjects, both in America and on the Continent.

AT the annual general meeting of the members of University College, London, held last week, Lord Reay moved the following resolution on behalf of the council:—"That this meeting has heard with great satisfaction of the generous offer of the Drapers' Company to make themselves responsible for the debt upon the college to the extent of 30,000*l*., and of another friend

of the college to give an equal sum, conditionally upon the college being incorporated in the University of London, and concurs in the resolution of the council to enter into negotiation with the University with a view to the incorporation." He said the idea of incorporation was not a new one, because when the statutory commissioners were sitting for the purpose of framing the statutes for the reconstitution of the University of London, the council represented to them the intention of the founders and benefactors of University College would only be carried out by incorporation. The commissioners, however, felt that the terms of the Act did not make it possible for them to give effect to the proposal. The council had not abandoned the policy, and since the beginning of the present year events had taken place that brought it within the range of speedy realisation. With regard to the appeal for funds, it was quite obvious that if the work which was being carried out was to be continued, the funds would need a much larger increase. Lord Monkswell, who seconded the resolution, hoped there would be many rich men who would follow the example of their anonymous benefactor. He trusted that the negotiations which they were having with the University of London would be successful, and said that no conciliatory efforts on their part would be wanting. The resolution was adopted.

THE address delivered before the Association of Technical Institutions on January 31, by the president, Lord Avebury, is published in the official report of the proceedings of the meeting. The address was, in a large part, a plea for more liberal recognition of science and modern languages in the time-tables of our schools, supported by the opinions of commissions and other competent authorities. Classics has at present too large a portion of the available time, and science is only tolerated. "An education which excludes science is a one-sided education, and the most learned classical scholar, if he knows nothing of science, is but a half-educated person after all." But the question is not so much one of culture as of equipment for national progress. When, as Lord Avebury remarks, we find commission after commission (composed of men selected for their wisdom and experience), after careful and patient inquiry, one after the other, and with remarkable unanimity, pointing to the neglect of science and of modern languages in our educational system as a grave evil, it must surely be worth while to inquire whether these warnings have been taken to heart, or the recommendations have been carried into effect. Lord Avebury gives instances, most of which are known to readers of NATURE, of industrial progress in Germany due to technical training. "It is evident then," he concludes, "that the technical instruction of Germany has been a very remunerative investment; in the first instance, no doubt, a great national advantage, but a boon also to the world as a whole. These figures bring home to us clearly the importance of the subject. It is obvious how keen competition is going to be. If we are to hold our own, we must supplement the rule of thumb in our workshops—very important in itself—by the rule of brain. Emerson once said that this country 'is prosperous because steam is half an Englishman.' We all hope that Britannia may long rule the waves, but it is most important that she should rule the steam engine and the dynamo as well."

SCIENTIFIC SERIAL.

American Journal of Mathematics, vol. xxiv. No. 1, January.—Cyclic subgroups of the simple ternary linear fractional group in a Galois field, by L. E. Dickson. This paper is an addition to the author's previous one in vol. xxii. pp. 231-252. It gives proofs of results therein stated and adds some new theorems allied to them. The question discussed concerns the substitutions

$$x^1 = \alpha^r x,\ y^1 = \alpha^s y,\ z^1 = \alpha^{-r-s} z,$$

where α is a primitive root of the Galois field of order p^n. Two cases arise according to the value of the greatest common divisor d of 3 and $p^n - 1$.—Curves of triple curvature, by J. G. Hardy. The object of the paper is to add to the results which have been obtained concerning curves L of triple curvature. Equations of motion for systems in a four-dimensional space have been deduced and used to introduce the notion of an instantaneous plane of rotation. The derivation is not new, but it is retained for the sake of clearness. By constructing the principal tetrahedroid at a point of a curve of triple curvature and studying its motion by means of the kinematical equations obtained, geometrical interpretations of the six rotations and also a set of formulæ corresponding to the Serret-Frenet formulæ for curves of double curvature have been arrived at. These formulæ have been applied to the study of curves L and, in particular, of the osculating hypersphere and the locus of its centres. Many of the results were contained in a paper read before the mathematical seminary of the Johns Hopkins University in 1898, and so were antecedent to the articles by Prof. Lovett and Mr. Hatzidakis in vol. xxii. The subject may be studied in Brunel, *Math. Ann.* xix. p. 48; Pirondini, *Giom. di Mat.* xxviii. p. 237; and Piccioli, *Giom. di Mat.* xxxvi. p. 273.—Primary prime functions in several variables, and a generalisation of an important theorem of Dedekind, by H. Hancock. Reference is made to Kronecker, "Grundzüge," &c., § 4, p. 11; Runge, *Crelle*, Bd. xcix. p. 89; Mandl, *Crelle*, cxiii. p. 252; Meyer, *Math. Ann.* Bd. xxx. p. 30, and to other memoirs.—On certain properties of the plane cubic curve in relation to the circular points at infinity, by R. A. Roberts. In this second part, which is on certain plane cubic curves and their angles of intersection, with some account of conics cutting orthogonally, the author investigates some methods of generating certain plane cubic curves in such a way that their angles of intersection assume a simple form.—Estimate of Peirce's linear associative algebra, by H. E. Hawkes. In the fourth volume of the *Journal* there appeared a memoir by Peirce in which he attempted to classify and enumerate hyper-complex number-systems. This does not seem to have received on the Continent the credit it deserves. In order that it should receive due recognition, Mr. Hawkes claims that three questions must be discussed, viz., what problem did Peirce attack, and to what extent did he solve it? what relation does this problem bear to that treated by Study and Scheffers? and to what extent do Peirce's methods assist in the solution of that problem? In the present article, Mr. Hawkes discusses the first two questions, and discusses the last in the *Transactions* of the American Mathematical Society, vol. iii. A historical review accompanies the article. It may be remembered that Mr. Spottiswoode drew attention to Peirce's work in his presidential address before the London Mathematical Society (vol. iv. p. 152); see also Cayley, "Collected Works," xi. p. 465; xii. p. 465.—Dr. G. A. Miller furnishes a short note on groups defined by the orders of two generators and the order of their product.—A fine portrait of Prof. Benjamin Peirce is given with the number.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 12, 1901.—"The Effective Temperature of the Sun." By W. E. Wilson, D.Sc., F.R.S.

In a memoir by the author and Mr. P. L. Gray, entitled "Experimental Investigations on the Effective Temperature of the Sun," published in the *Phil. Trans.* Roy. Soc. A. vol. clxxxv. (1894), the method described was as follows:—A beam of sunlight reflected from a Stoney single-mirror heliostat was directed into one aperture of a Boys' differential radio-micrometer. The other aperture received the radiation from a small circular area of a strip of platinum raised to any desired temperature by an electric current, this temperature being measured by the linear expansion of the platinum as in Joly's meldometer. Knowing then the ratio of angular diameter of radiating area of platinum to that of sun, the temperature of the platinum strip, the emissivity of bright platinum and the amount of the sun's radiation lost by absorption in the earth's atmosphere and by reflection from the heliostat mirror, it is possible in any assumption of a law connecting radiation with temperature to determine the effective solar temperature. The mean of a series of very accordant observations gave 6200° C. (absolute).

To protect the incandescent strip from draughts of air it was covered with a water-jacket of gilded brass. Possibly some of the radiation from distant parts of the strip may have been reflected between the polished walls and the strip itself and, ultimately escaping through the circular aperture fronting the radio-micrometer, reached it and so vitiated the result. Smoking the interior of the water-jacket sensibly reduced the amount of radiation and so proved this surmise correct.

It is also possible that changes in the surface condition of the platinum may effect its emissivity, which in the original memoir was taken at 0·35 that of lamp-black (Rosetti's estimate), so that it is a distinct advantage to abolish the platinum strip as a source of radiation and to substitute a uniformly heated enclosure which would radiate as an absolutely black body.

In 1895 Mr. Lanchester pointed out to the author that such an enclosure would be a theoretically perfect radiator; while Lummer, Paschen and others using radiation from such a source have confirmed in a remarkable manner Stefan's law of radiation, viz. $R = aT^4$.

The radiator employed was a porcelain[1] tube 2 feet long and 1 inch internal diameter fitted into a Fletcher gas-tube furnace. A plug of asbestos was inserted in the tube about 10 inches from the end remote from the radio-micrometer, and resting against this plug was the end of a Callendar platinum resistance thermometer. In front of the open end of the tube was a rectangular aperture 5 mm. wide in a large brass water-screen; a slide closing this aperture was moved by a micrometer screw reading to 0·01 mm. This aperture was 66·3 mm. from the surface of the thermocouple (Fig. 1).

To make an observation, the tube was heated to as high a temperature as the furnace was capable of, and the radiation from the interior of the tube passing into the aperture (B) of the radio-micrometer was adjusted by the micrometer screw until a balance was obtained with the radiation of the sun through the aperture (A).

After a series of observations had been made, the arrangement was altered so that the radiation from the tube should enter aperture (A) and from the sun aperture (B) of the radio-micrometer, and in this position a second series of observations was taken. The geometric mean of the results of the two groups gives the effective temperature of the sun.

The mean of the observations thus made gave 5773° C. (absolute) as the sun's effective temperature.

In calculating this result, Rosetti's coefficient of atmospheric absorption, viz. 0·29, has been used. Taking Langley's value, viz. 0·41, the result will be 6085° C. (absolute).

It is interesting to allow for the effect of absorption in the sun's atmosphere. Assuming the results of Wilson and Rambaut's experiments (*Proceedings* Royal Irish Academy, 1892, vol. ii. No. 2), the value 6863° C. (absolute) is deduced as the effective temperature of the sun's photosphere.

Physical Society, February 28.—Prof. S. P. Thompson, president, in the chair.—A paper on focal lines and anchor-ring wave-fronts was read by Prof. J. D. Everett. When a small cone of rays is obliquely incident on a spherical reflecting or refracting surface, the rays after reflection or refraction no longer compose a true cone. Instead of meeting in a point they form a narrow neck, and this neck is flattened in two places called the *two focal points*, the planes of flattening being at right angles to each other. Optical writers give the name *focal lines* to the sections of the pencil made at the focal points by planes perpendicular to the axis of the pencil; but it would be more appropriate to give the name to the sections which most nearly resemble lines, whatever angle they make with the axis of the pencil. Attention is drawn in the present paper to the case in which the wave-front in one of its positions is a tore (or anchor-ring). Even when dealing with wide-angled pencils there are then two well-defined focal lines, the primary focal line being what may be called the circular axis of the tore, and the secondary a portion of the line about which the generating circle turns to form the anchor-ring. Toric wave-fronts can be produced by reflection from a mirror made by allowing an ellipse or portion of an ellipse to revolve completely round an ordinate erected at one focus, and employing it to reflect rays diverging from a small source at the other focus. The primary line is always real; the secondary is real or virtual according to the position of the area of incidence of the pencil.—A paper entitled "Contributions to the Theory of the Resolving Power of Objectives" was read by Prof. Everett. The practical limit to the resolving power of objectives depends upon the blurring due to diffraction. Observations on double stars for the purpose of investigating the separating power of telescopes have been made by Dawes, who arrived at the conclusion that the angular distance between the two components, when they are nearly equal in magnitude and are just separated, is given by the formula, 4·56 seconds divided by the diameter of the objective in inches. Foucault also investigated the matter experimentally, and in 1830 Airy calculated the brightness at various points of the spot and rings which constitute the image of a point source formed by an objective. If the extreme difference of optical path for disturbances coming from different points of a concave wave-front to a point at lateral distance b from the geometric focus is made equal to the wave-length of light, a value for b is obtained which represents with fair accuracy the limit of separation as determined by experiment. The formula agrees with that of Dawes if λ = ·56 micron., whereas the wave-length of the brightest ray is usually taken as ·55 micron. In the case of microscopes the author has supposed that the formula for the minimum distance b still holds good, and combining this equation with the sine condition applicable to optical systems giving sharp flat images, he has deduced the expression which has been extensively used

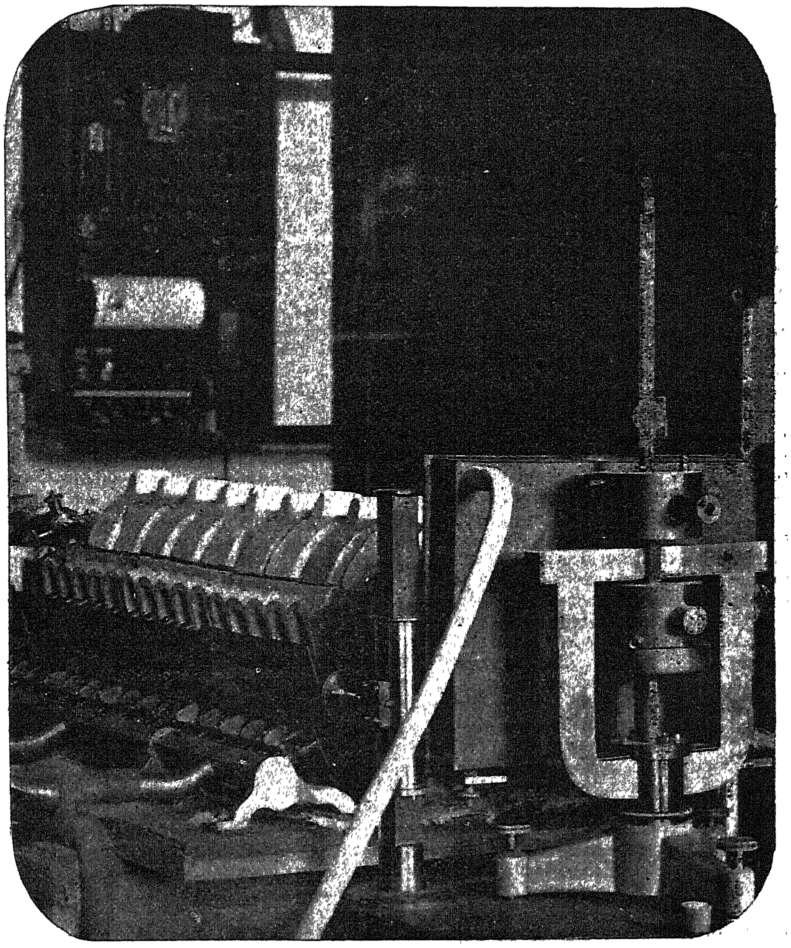

FIG. 1.—Differential radio-micrometer with tube furnace.

[1] In later experiments an iron tube was substituted.

for the distance between lines or points which can be barely separated. Microscopic test objects are not self-luminous, like double stars, but are viewed by transmitted light. If no condensing arrangement is employed, the pencil of light sent by a point of the object to the objective consists, in effect, of rays from different sources. The result of this is that the image of the point is larger and more blurred. The cure for this evil is furnished by employing a condenser of high quality, to throw upon the part of the object under examination a very sharp image of the source of illumination. Each point of the object thus gets its light from its own special point of the source; the object, therefore, acts as if it were self-luminous, and the power of the instrument is increased. The benefit derived from sharp focussing on the object explains the advantage of using an achromatic condenser and not, as formerly recommended by Abbe, one which is not achromatic. Another advantage of sharp focussing by the condenser is that there can be no interference of the light from different parts of the object. The author then gives an explanation of the advantage of oblique illumination, and arrives at the view of microscopists that the obliquity of illumination should be rather less than the obliquity of the extreme rays of the incident pencil. The paper concludes with Hockin's proof of the sine condition.—A paper on the absorption, dispersion and surface colour of selenium, by Prof. R. W. Wood, was read by the secretary. The dispersion of selenium has been investigated by means of prisms made in the same manner as the cyanine prisms already described by the author. The substance is much more transparent than cyanine, and prism angles of four or five degrees can be employed. Determinations were made with three selected prisms down to wave-length 61; below this the interferometer method was employed. Uniform films of selenium were obtained on plates of plane parallel glass by means of a flat selenium kathode in a high vacuum, and the displacements of the interference fringes by the introduction of the films were measured for lights of different known wave-lengths. Wedge-shaped films were then employed, which allowed the displacement for any wave-length to be measured for the maximum thickness capable of transmitting the light. An advantage of the wedge-shaped films is that the fringes are curved and the displaced fringe can be easily identified with the undisplaced. The refractive indices obtained in the red by prisms were used as a basis for the calculation of the indices in the rest of the spectrum from the interferometer measurements. Determinations were made in this way down to wave-length 40, beyond which it was impossible to go owing to the powerful absorption. A curve has been plotted showing the relation between refractive index and wave-length. It has a maximum at wave-length 50 (·00005 cm.), where the refractive index is 3·13. An examination of the light transmitted by a thin film showed that there was no return of transparency in the ultra-violet at least down to wave-length 28. Photometric measurements were made of the transmitted light, both visible and ultra-violet, and a curve has been drawn with wave-lengths as abscissæ and extinction coefficients as ordinates. It is proved that the extinction coefficient increases continuously with decrease in wave-length as far as wave-length 22, where the coefficient has as high a value as in the case of metals. The author concludes that the absorption is due, not to a single band, but to a series of overlapping bands. The object of this work was to determine whether there was a return to partial transparency in the ultra-violet region. This question appears to be answered in the negative, although a possible turning-point in the curve might be masked by the reflection coefficient of selenium. The high value of the extinction coefficient in the ultra-violet led the author to look for traces of selective reflection in this region. The light of an arc lamp was reflected successively from six surfaces of selenium, and the image of the crater after the sixth reflection, although faint, was without colour or excess of ultra-violet light. If the data obtained in the paper for refractive index and extinction are used in the formula for reflection from an absorbing medium, a result is arrived at which indicates that the reflection increases rapidly with decreasing wave-length. As multiple reflections from selenium surfaces give no trace of colour, errors must exist in either the refraction or the extinction curve. The author suggests that in the case of films of thickness less than the wave-length of light, the displacement of the interference fringes does not give a measure of the refractive index.—The chairman exhibited some tellurium mirrors made in the same way as the selenium ones used by Prof. Wood.

Chemical Society, February 19.—Prof. Emerson Reynolds, V.P.R.S., president, in the chair.—The union of hydrogen and oxygen, by Mr. H. B. Baker. The author has devoted, during the last few years, much attention to the inhibition of chemical action produced by thoroughly drying substances, but until quite recently had not succeeded in so completely desiccating a mixture of oxygen and hydrogen as to prevent the explosion of such a mixture when electric sparks were passed through it. He has now found that by electrolysing a solution of barium hydroxide it is possible to obtain a mixture of these gases which, when dried over phosphorus pentoxide, is no longer exploded by electric sparks or by the application of intense heat, the highly explosive character of the mixture, however, being regained by the introduction of a mere trace of moisture.—Enzyme action, by Prof. A. J. Brown. Some years ago the author showed that the fermentation of saccharine solutions by yeast does not proceed according to the ordinary mass law which governs chemical reactions. On the other hand, O'Sullivan and Tompson found that the inversion of cane sugar by the enzyme invertase follows this law. Since both of these reactions, in the light of Buchner's researches on zymase, are produced by enzymes, there appeared to be a remarkable difference in the operation of the latter. The inversion of sucrose by invertase has, therefore, been reinvestigated by the author, who finds that this reaction does not progress according to the mass law, but in precisely the same way as the fermentation of sugars by yeast. The explanation of this feature of enzyme action is, the author thinks, the formation of an intermediate unstable compound between the enzyme and the substance it is decomposing, thus introducing a time factor which obscures the mass influence.—On the velocity of hydrolysis of starch by diastase, with some remarks on enzyme action, by Mr. H. T. Brown, F.R.S., and Mr. T. A. Glendinning. The authors confirm the results obtained by Prof. Adrian Brown with regard to the progression of hydrolytic reactions caused by enzymes, but they explain the peculiarity exhibited in a different manner, an attempt being made to connect enzyme hydrolysis with acid hydrolysis, the unstable combination of starch or sugar with the enzyme being regarded as the hydrolyte and the active dissociated water molecules present as the hydrolysts.—Polymerisation products from diazoacetic ester, by Dr. O. Silberrad. Three series of polymerides are obtainable from diazoacetic ester, and the present paper gives an account of the results of experiments on the so-called "pseudo-diazoacetamide," whereby the author has been able to assign a constitution to this substance.—Condensation of phenols with esters of unsaturated acids, by Dr. S. Ruhemann. The author describes the products obtained by the action of ethyl chlorofumarate on guaiacol and α-naphthol, whereby a benzopyrone and a naphtharone are respectively formed.—The chemical change produced by the immersion of lead in distilled water, by Dr. F. Clowes. Distilled water, recently boiled, exerts very little action upon metallic lead immersed in it, but unboiled distilled water converts the metal into hydroxide of lead, which remains in solution, and into a hydrated carbonate, which is precipitated. The principal agent in effecting this change appears to be the oxygen dissolved in the water.—The bases contained in Scottish shale oil, part i., by Messrs. F. C. Garrett and J. A. Smythe. The fraction of Broxburn shale oil boiling below 164° contains pyridine and several of its homologues.—Note on liquid nitrogen peroxide as a solvent, by Prof. P. F. Frankland, F.R.S., and Dr. R. C. Farmer. The authors note that in their recent paper on this subject they inadvertently omitted any reference to the previous work by Bruni and Berti, who investigated the cryoscopy of nitrogen peroxide solutions of various substances and pointed out the associating power of this solvent.

Linnean Society, February 6.—Prof. S. H. Vines, F.R.S., president, in the chair.—Prof. Reynolds Green, F.R.S., exhibited some primroses which showed the rare phenomenon of sepalody. The corolla was green and the limbs of the petals were rugose and of a texture almost comparable with that of the foliage-leaves. He also showed another specimen in which the calyx as well as the corolla was petaloid. Both specimens were received from a garden in the north of England.—Messrs. H. and J. Groves exhibited a series of British hybrid batrachian Ranunculi, together with specimens of their supposed parents. They pointed out that the hybrids were usually characterised by (1) being intermediate in appearance between the two parents, having some of the distinctive characters of each, but with a

more vigorous vegetative growth, and (2) by the fruit being mostly abortive and the peduncles not becoming recurved.—Mr. Francis Darwin, F.R.S., read a paper on a method of investigating the gravitational sensitiveness of the root-tip, showing the apparatus used and lantern-slides of seedlings under experiment. Confining himself to the modern development of the question, the author remarked that the observations of Czapek and of Pfeffer having been contradicted by Wachtel, it had become desirable to confirm these observations by employing a different method. The apparatus used consisted of a counter-balanced lever 53 cm. long, able to turn in any direction by being mounted on knife-edges. Seedlings of the bean and the pea were employed, and glass tubes, straws and dandelion scape were in turn used to contain the root-tip, and, by the aid of certain mechanical appliances, to prevent the root slipping out of the tube. The tip being fixed, the remaining part of the root and the hypocotyl became curved in varying degrees, due to the continued stimulation of the root-tip. The result has been confirmation of the observations made both by Czapek and by Pfeffer.—Dr. D. H. Scott, F.R.S., gave an account (illustrated by lantern-slides) of an extinct family of ferns—the Botryopterideæ, our knowledge of which is primarily due to the researches of M. Renault.

Zoological Society, February 18.—Prof. G. B. Howes, F.R.S., vice-president, in the chair.—Mr. W. B. Tegetmeier exhibited and made remarks upon the skull of a supposed hybrid between the sheep and the pig, named "cuino" by the inhabitants of Mexico, where it is stated to be extensively reared as an agricultural animal. The skull was clearly that of a pig. —Dr. C. I. Forsyth Major exhibited and made remarks upon some remains of voles from the Upper Val d'Arno (Italy) and from the Norwich Crag, representing *Microtus pliocaenicus* (Maj.) and *Microtus intermedius* (Newt.). Dr. Forsyth Major considered that they belonged to a distinct genus, which he proposed to name Mimomys.—Mr. R. Lydekker exhibited, on behalf of Mr. Rowland Ward, two pairs of antlers and a skull of an elk from Siberia (beyond the Altai). Mr. Lydekker pointed out that, although belonging to adult animals (as the dentition of the skull indicated), the antlers had practically no palmation—a characteristic which induced him to propose the specific name *Alces bedfordiae* for the Siberian elk.—Dr. C. I. Forsyth Major gave a description of *Mustela palaeattica*, Weith., from the Upper Miocene of Pikermi and Samos, based chiefly on an almost perfect skull from Pikermi in the Turin Museum. —Mr. Oldfield Thomas, F.R.S., read a description of two new rodents discovered by Mr. P. O. Simons near Potosi, Bolivia. The one proposed to be called *Neoctodon simonsi* was allied to Octodon, but had simpler teeth, without enamel infoldings, and a bushy tail, the size and external appearance being much those of *Neotoma cinerea*. The second, called *Andinomys edax*, was allied to Phyllotis, but had much larger, more complicated and highly hypsodont teeth; in general appearance it was like a large Phyllotis, such as *Ph. darwini*. Its head and body measured 160 mm. and its tail 145 mm.—Mr. Oldfield Thomas also read a paper on some new mammals from northern Nyasaland, which had been contributed to the National Museum by Commissioner Alfred Sharpe, C.B., and Colonel Manning. —Mr. Boulenger, F.R.S., made remarks on the characters of the very young form of Polypterus, connecting the early stage recently discovered by Mr. Budgett with the more advanced stages described by Dr. Steindachner and himself. Characters were pointed out by which the young of *Polypteri lapradii*, *congicus*, *endlicheri*, *weeksii*, *senegalus* and *palmas* could be distinguished. Special attention was drawn to young specimens of *P. lapradii* from Nigeria, in which the external gills measured up to one-third of the total length.—Mr. Boulenger also drew attention to a new snake of the genus Psammophis, from Cape Colony, of which a specimen had been presented to the British Museum by Dr. G. Leighton. The name *P. leightoni* was proposed for this new species.—Mr. F. E. Beddard, F.R.S., read a paper dealing with the tuft of vibrissæ commonly met with upon the wrist of mammals belonging to the orders Lemuroidea, Carnivora, Rodentia and Marsupialia. It was pointed out that this structure was found in both sexes and in a large proportion of the genera and species belonging to the mammalian groups mentioned. As to other orders of mammals, the only ungulate in which they had been discovered was stated to be Hyrax; of edentates, the armadillos alone possessed these vibrissæ upon the wrist.

CAMBRIDGE.

Philosophical Society, February 17.—Prof. Macalister, president, in the chair.—The histology of the endosperm during germination in *Tamus communis* and *Galium tricorne*, by Mr. Walter Gardiner, F.R.S., and Mr. Arthur W. Hill. After briefly describing the stages in the germination of *Tamus communis*, the authors gave an account of the histology of the endosperm and of the changes which accompany the dissolution of the cell walls.—Demonstration on the dimorphism of the Foraminifera, by Mr. J. J. Lister.—On the differentiation and integration of divergent series, by Mr. G. H. Hardy. The paper contains some discussion of the general principles in accordance with which we may attribute conventional values to analytical expressions which do not represent any determinate quantity when interpreted in the ordinary way. In particular it is shown how they lead to Borel's definition of the sum of a divergent series. It also contains investigations as to the possibility of applying the ordinary operations of the calculus to divergent series whose sums are defined as by Borel. A series of general theorems is proved, and applications are made to the evaluation of definite integrals and the theory of trigonometrical series.

PARIS.

Academy of Sciences, February 24.—M. Bouquet de la Grye in the chair.—On transcendental meromorphs defined by differential equations of the second order, by M. Paul Painlevé.—On the origin of stolonial formations, by M. Edmond Perrier.—On the impossibility of certain permanent states in viscous liquids, by M. P. Duhem.—M. Baillaud was elected a correspondant for the section of astronomy in the place of the late M. Souillart.—On some transformations of Backland, by M. E. Goursat.—The application of Duddell's singing arc to the measurement of small coefficients of self-induction, by M. Paul Janet. It is known from the experiments of Duddell that there is a simple relation between the period of the note given out by a singing arc, the capacity and the self-induction of the circuit. By measuring the intensity of the current with a thermal ammeter, the difference of potential with a thermal voltmeter, and working with condenser of known capacity, it is shown that coefficients of self-induction smaller than 0·003 Henry can be measured.—On a capillary electrometer, by M. Pierre Boley. The Lippmann capillary electrometer will not work with saturated liquid amalgams which are not sufficiently mobile in the narrow tubes. It has therefore been modified to meet this special case. Its sensibility was found to be of the order of ·00003 volt.—On some properties of azobenzene and hydrazobenzene, by MM. P. Freundler and L. Béranger. The Friedel and Crafts reaction cannot be utilised for the preparation of ketones from azo-bodies.—On the constitution of dibutylic and diœnanthylic alcohols, by M. Marcel Guerbet. By a careful study of the oxidation products of these two alcohols, it was found that they are represented by the formulæ $CH_3.CH(C_4H_9).CH_2.CH_2OH$ and $CH_3.CH_2.CH_2.CH(C_7H_{15}).CH_2.CH_2.OH$.—On the polymerised state of ordinary indigo and the isomeric transformation of indigotin into indirubin, by M. L. Maillard.—On some reactions obtained with the aid of magnesium amalgam, by M. L. Meunier. Magnesium amalgam attacks ethyl alcohol even in the cold, magnesium ethylate being formed. The alkyl iodides are more readily attacked by this reagent than by the copper-zinc couple, the saturated hydrocarbon being formed. Ordinary aldehyde reacts violently with magnesium amalgam, the symmetrical dioxybutane, $CH_3.CHOH.CHOH.CH_3$, being produced.—On the constitution of tariric acid, by M. Arnaud.—A new method for characterising the pseudo-acids, and on its application to the oximidocyanacetic esters, by M. P. Th. Muller. Measurements are made of the molecular refraction and molecular dispersion.—On some derivatives of methyl-nonyl-ketone, by M. H. Carette. By the addition of hydrocyanic acid to this ketone and the subsequent hydrolysis of the nitrile produced, the corresponding amide and acid were obtained, the properties of which are described.—On an important source of error in the examination of diastases, by MM. Emm. Pozzi-Escot. The colour reaction with tincture of guaiacum, which has been relied upon in many researches, is now found to fail in certain cases. From this it follows that a certain number of published works on the diastases and their localisation in particular cells are of no value. —On the analysis of ceramic products, by M. V. de Luynes.

For the analysis of objects in relief on porcelain of a different composition, advantage is taken of the action of a layer of drying glycerine in removing the surface of porcelain or glass.—Search for fatty acids in contaminated waters, by M. H. Causse. The amounts of fatty acids present in a water are regarded by the author as measuring the contamination, and methods are given for separating and estimating the quantities of such acids present.—The resistance of the red globules of the blood determined by its electrical conductivity, by MM. Calugareanu and Victor Henri. In the determination of the resistance of the red globules of the blood, it is necessary to determine both the hæmoglobin and the salts. This determination can be made with great precision by measuring the electric conductivity of the solutions. The application of this method has shown that the red globules may lose a part of their salts without any corresponding change in their colouring-matter.—On the simultaneous production of indoxyl and urea in the organism, by M. Julius Gnezda.—On asphyxia by the gases of drains, by M. Hanriot. Accidental cases of asphyxia in drains are usually attributed in the text-books to the presence of sulphuretted hydrogen. Analyses of the air in ventilated drains showed that this gas was either absent or present in such small proportion as to have no appreciable effect. In unventilated drains the amounts were larger, ·03 to ·05 per cent., but still too small to exert a poisonous action. The air in the unventilated drains was irrespirable on account of the large amount of carbonic acid present and the deficiency in oxygen, and hence no disinfectant that might be proposed would meet the case. The only practicable means of rendering the air of a drain inoffensive is energetic ventilation at the time the workmen are descending.—On the germination of Onguekoa and Strombosia, by M. Edouard Heckel.—On the tectonic of the neighbourhood of Biarritz, Bidart and Villefranque, by M. Leon Bertrand.—On the existence of phenomena of overlapping in the subbetic zone, by M. René Nicklès.—A geological map of Bambouk, in the French Soudan, on the scale of 1/250,000, by M. Alex. J. Bourdariat.—On the constitution of the suboceanic soil, by M. J. Thoulet.

DIARY OF SOCIETIES.

THURSDAY, MARCH 6.

ROYAL SOCIETY, at 4.30.—On the Spark Discharge from Metallic Poles in Water: Sir Norman Lockyer, F.R.S.—Experimental Researches on Drawn Steel. Part I. The Influence of Changes of Temperature on Magnetism. Part II. Resistivity, Elasticity and Density, and the Temperature Coefficients of Resistivity and Elasticity: J. R. Ashworth.—On the Effects of Magnetisation on the Electric Conductivity of Iron and Nickel: G. Barlow.—The Differential Equations of Fresnel's Polarisation-Vector, with an Extension to the Case of Active Media: J. Walker.—On a convenient Terminology for the various Stages of the Malaria Parasite: Prof. E. Ray Lankester, F.R.S.

LINNEAN SOCIETY, at 8.—On some New Species of Lepadidæ in the British Museum (Nat. Hist.): Prof. A. Gruvel.—On the Morphology of the Brain in the Mammalia, with Special Reference to the Lemurs, Recent and Extinct: Dr. G. Elliot Smith.

RÖNTGEN SOCIETY, at 8.30.—Localisation; with Demonstration of a Simple Direct Reading Apparatus: Dr. Barry Blacker.

CHEMICAL SOCIETY, at 8.—The Slow Oxidation of Methane at Low Temperatures: W. A. Bone and R. V. Wheeler.—Isomeric Additive Compounds of Dibenzyl Ketone and Deoxybenzoin with Benzal-*p*-toluidine, *m*-Nitrobenzalaniline and Benzal-*m*-nitraniline, Part III.: F. E. A NEW MANUAL OF THE PROTOZOA.

The Protozoa. By Gary N. Calkins. Columbia University Biological Series, VI. Pp. xvi + 347; 153 text-figures. (New York: The Macmillan Co. London: Macmillan and Co., Ltd., 1901.) Price 12*s.* 6*d.* net.

BIOLOGISTS have understood for a long time past the importance of the study of the Protozoa as an indispensable aid to the solution of some of the most fundamental problems of biology. Of recent years, however, a lively interest in this class of organisms has been awakened in many others besides those whose field of investigation includes the Protozoa amongst its recognised subjects. Medical researchers, for instance, require now to know more about the simplest forms of animal life than they were taught, as students, in their elementary courses of biology, and even the general public has had its attention directed to "microbes" by the recent discoveries concerning the etiology of malaria and the wonderful life-history of its minute parasite. The time is opportune, therefore, for the publication of a general account of the Protozoa, and the latest addition to the well-known Columbia Series is a handy volume which will be welcomed by many classes of readers. The author has not aimed at putting forward an exhaustive, severely scientific treatise upon the group in question. His work may be described rather as a simple and intelligible introduction to the study of the Protozoa and of the many fascinating biological problems connected with, or illustrated by, this subdivision of the animal kingdom, in such a way as to awaken the interest of the beginner, no less than to strengthen the hands of the expert. The book is written in plain language, with avoidance of unnecessary technicalities, and is profusely illustrated by a great number of very excellent figures, in the preparation of which the author acknowledges the assistance of his wife, whose skilful draughtsmanship cannot be praised too highly.

The author treats his subject, as stated in the preface, from three points of view: (1) the historical, which occupies the first chapter; (2) the comparative, on which five chapters are spent; and (3) the general, to which the last three chapters are devoted. The historical and introductory chapter gives an extremely interesting account of the progress of our knowledge of the Protozoa, and traces the gradual elimination of the many erroneous notions prevalent even not so very long ago.

The comparative account is a useful review of the whole group and of the four principal subdivisions, the Sarcodina, Mastigophora, Sporozoa and Infusoria. The author is extremely up to date in his facts, and makes use of the most recent observations and discoveries. In the chapter on Sporozoa we find Siedlecki's recent account of the conjugation of the sporoblasts in *Monocystis* (*Lankesteria*) *ascidiae* taken as typical for the class (p. 151) and made the basis of six good diagrammatic figures representing the "scheme of sporulation in gregarinida" (Fig. 84, p. 152). The book must have been out of the author's hands before the publication of Cuénot's recent memoir describing a perfectly similar type of conjugation in the common Monocystis of the earthworm, but it is nevertheless unfortunate that the now exploded account put forward by Wolters for this type should be quoted so frequently (pp. 157, 235 and elsewhere), especially as Wolters' statements are directly at variance with the "scheme of sporulation" to which reference has been made.

The three general chapters deal with sexual phenomena in the Protozoa, with the special morphology of the Protozoan nucleus, and with some problems in the physiology of the Protozoa respectively. The sexual phenomena are divided into four categories—union of similar adult individuals, of similar but different-sized individuals, of swarm spores or reduced individuals, and, lastly, of "eggs and spermatozoa," *i.e.* of highly differentiated gametes. A great deal of very interesting matter is brought forward under each heading, but the facts relating to the Coccidia, which form the bulk of the fourth subdivision, are set down in a very inaccurate manner, and require revision. It is not true, for instance, to say that "so far as the nucleus (of the macro gamete) is concerned, . . . no maturation process has been recorded," unless the term maturation be used in a very restricted sense. In *Adelea ovata* the entrance of a male element is not effected through a special opening or micropyle, as stated; but perhaps *Coccidium proprium* is meant, where this does occur. Again, it is incorrect to say that in *Adelea ovata* the microgamete divides twice while in contact with the macrogamete, and that three of the resulting nuclei are eliminated. It is the microgametocyte which divides in this way to furnish four microgametes, one of which fertilises the "egg." In a book which bears evidence of so much careful and well-considered work, it is strange to find so many misstatements so close together, but the whole paragraph (pp. 229-232), from which is taken the above statement concerning the microgamete, is confused and contradictory, since, beginning by referring to Adelea by name, and without introducing the name of any other species, it goes on to make statements which evidently refer to Coccidium, and then to institute comparisons between the facts stated and the processes occurring in other Coccidia, including Adelea itself.

In the chapter dealing with the nucleus, an attempt is made to trace the steps in the elaboration of the structure of Protozoan nuclei and of the mechanism of nuclear division. Four stages are recognised in the evolution of nuclear structure: (1) compact spheres of chromatin, multiple division of which is the prelude to the reproduction of the cell; (2) nuclei with membranes, enclosing each one or more chromatin masses or "karyosomes," which break up to form granules, and the granules unite secondarily in lines forming primitive chromosomes; (3) nuclei without karyosomes, with granules distributed widely over the nuclear framework; (4) nuclei with granules as in (3), or aggregated into "net knots" which break up into granules at the period of nuclear division, the granules then coming together in lines which segment into chromosomes of definite number and size. The fourth and highest of these stages is that found in Metazoa and Metaphyta. The author comes to the conclusion

that "the centre of activity in the division of the Protozoan cell, as in the Metazoa, resides in a special structure," which he terms the division centre, regarding it as "a specific substance different from the chromatin and from the cytoplasm." The origin of the division centre is doubtful, but "the widespread intranuclear condition favours the view that it originated there." It is not possible to deal here with the wealth of interesting facts which are marshalled in support of these conclusions, but it is strange that although Schaudinn's now well-known figure illustrating the life cycle of Coccidium is given twice over, no mention is made of his striking observations upon the origin of karyosome, and the *rôle* played by it in nuclear division, in the "endogenous" cycle of this type, nor is Schaudinn's memoir (1900) cited in the bibliography, which contains few references later than 1899.

In the chapters upon physiology, the facts and conclusions are arranged under the headings Intracellular Digestion, Respiration, Secretion and Excretion, Irritability and, finally, General Considerations.

In a work of this size there is, of course, much to criticise, and we may draw attention to a few errors or omissions, such as will always creep into the best regulated manuscripts. Spermatozoa are said, on p. 8, to have been withdrawn from the Protozoa during the present century! The Coccidian genus Minchinia is termed Myxinia on p. 20 (description of Fig. 6). In Fig. 31 B (p. 63) is depicted an associating couple or "syzygy" of polycystid gregarines, which look not unlike the common *Clepsydrina ovata* from the meal-worm; but the figure is labelled *Monocystis agilis*, Leuck. (*sic*). For Fig. 77, illustrating the development of a gregarine, Wasielewski is given as the authority, instead of the veteran investigator of the Sporozoa, Aimé Schneider. When the author states, on p. 146, that the Sporozoa are mononucleate (*sic*), "with the exception of the multinucleate Myxosporidiida," he should have added "and Sarcosporidiida," since a uninucleate Sarcosporidian has not yet been seen, leaving out of account the spores and reproductive bodies.

These are all trifles, but there is one feature of the book to which we wish to take exception; that is the author's practice of altering the form of well-known and familiar names of classes and orders. A similar tampering with names universally accepted and employed, in the vain effort to strive after uniformity—vain because in many cases it is very doubtful whether a given group of animals should be considered as a subclass, order or suborder—was a blemish upon the encyclopædic treatment of the Protozoa by Delage and Hérouard in the "Zoologie Concrète," where we find such monstrosities as "Ciliæ" and "Flagellia" for what everyone terms Ciliata and Flagellata. The desire of the author under review is to make all the subclasses end in "idia," the orders in "ida," and he adds this termination even to groups which in common usage already have it, *e.g.* "Myxosporidiida," "Hæmosporidiida." But the author has not the courage of his convictions to the same extent as Delage, for while writing "Flagellidia" he shrinks from "Ciliidia" or "Suctoriidia," retaining the usual appellations Ciliata and Suctoria. Endeavours to alter names in this way, however desirable, are absolutely useless unless proposed by some international convention, sufficiently representative and authoritative for all to be agreed to follow its ruling. When attempted by individuals it only leads to confusion. Are we to speak o "Flagellia" with Delage, or of "Flagellidia" with Calkins? The majority of us will continue to say and to write "Flagellata" to the end of our days. While on the subject of terminology and nomenclature, it may be noted that the author actually names two new species; one in the description of Fig. 13, on p. 41, and another in that of Fig. 134, p. 251. The professed systematist and bibliographer must surely consider this a most reprehensible act in a work of this kind.

The work is provided with short special bibliographies at the end of each chapter, as well as with a general bibliography at the end of the book. The excellence of the figures has been pointed out, but it should be further noted that many of them are original, and of the latter we would draw special attention to the figure of division in Gonium (p. 129), to that illustrating a phase in the conjugation in Arcella (p. 218), and to the figure of mitosis in *Tetramitus chilomonas* [n. sp.] (p. 270). In conclusion, we heartily congratulate the editors of the Columbia University Biological Series on their latest volume, which keeps up the high standard of excellence of its predecessors.

E. A. M.

GREEK TOPOGRAPHY IN RELATION TO HISTORY.

The Great Persian War and its Preliminaries. By G. B. Grundy. Pp. xiii + 590. (London: John Murray, 1901.) Price 21*s.* net.

MR. GRUNDY has laid students of Greek history under an obligation by this work, but the obligation would have been greater if the bulk and price of the book had been less. The author seems, indeed, to have fallen between two publics. The scholar, who knows the literature of the subject, ancient and modern, will complain that he here labours the obvious and there ignores the essential, that his acquaintance with Greek history is superficial and his estimate of authorities uncritical, that the pages which present anything at once new and valuable are few out of many. The general reader will require more literary skill and lucid order in the story, and cannot be blamed if he prefers Herodotus in his native simplicity.

But it is probably neither as literature nor as history that Mr. Grundy would have us judge the book, but as a contribution to the topography of Greece and an essay in military criticism. Here he has done excellent service. The large-scale surveys of Thermopylæ and the field of Platæa are good bits of work, and will put the detailed discussion of those battles on a new plane. Mr. Grundy's topographical sketches are a welcome supplement to the maps, and show him to be no mean draughtsman. Most of them are better than the photographs with which they are interpersed, some (for example, the views of Marathon at p. 163, of Artemisium at p. 264, of the sound of Salamis at p. 392, of the panorama from Platæa at p. 502) are admirable pieces of line drawing.

To come to details, we could wish that the map of Thermopylæ covered more ground, even at some sacrifice

of scale. In the pass itself the mound and the Phocian wall are the only debatable points, and they might have been relegated (if necessary) to a little inset plan. (It is ridiculous, by the way, to treat the pretty story of the Spartans combing their hair as serious evidence for topography or "autopsy"—the other Greeks had to be invisible and the wall was a good excuse for hiding them, that is all!) But the real problems are concerned with the valley of the Asopus, the road into Doris, the site of Trachis and the path Anopæa, about the identification of which we have sometimes felt doubts. There must be a railway survey of the valley somewhere, which would give a base to work from, but Mr. Grundy is here less helpful than M. Hauvette, and does not even elucidate his own text—where, for example, is the Great Gable (p. 302)? Why is not Trachis the same as Heraclea, or its acropolis? What is the point of the polemic against Leake, who seems to have accomplished the not unprecedented feat of riding at six miles an hour? There is a useful note on p. 262 to show that "it seems to have been a recognised principle in later times that an effective defence of Oeta included the occupation of Heraklea as well as of Thermopylæ." But why not in earlier times too? Surely, if topography is worth anything as a test of the narrative of Herodotus, it points here to a serious omission.

Mr. Grundy has perhaps scarcely sufficiently guarded himself against the natural tendency to fix sites and positions on the authority of Herodotus and then triumphantly claim that the evidence of the topography confirms the story. We believe that he is right in his theory as to the "Island" at Platæa, but where the identification of so many points is so uncertain we cannot avoid an uncomfortable notion that a turn of the spade may any day undermine his whole construction of the campaign, not to say the narrative of Herodotus itself.

On the other battles of the war Mr. Grundy has little that is new to contribute and scarcely anything of a geographical character. His theory of the campaign of Marathon is essentially Busolt's early view, recently revived by Mr. Munro, of the battle of Salamis a development of Prof. Goodwin's. He scarcely seems to appreciate the full significance of the position at Artemisium, which covers all the landing-places between Tempe and Attica. Aphetæ is a dubious point. It is hard to reconcile Mr. Grundy's situation with the remark of Herodotus, that the wreckage of the first sea-fight drifted *out* to Aphetæ, which is badly misrendered in the words "was thrust in upon the Persian fleet." Mr. Grundy is much put about to find a reason for the Greeks taking the offensive in 479. He concludes that they feared the establishment of a Persian frontier at Cithæron. Obviously the Persians would keep all they could conquer, but why should they stop at Cithæron? and is not the real difficulty the Greek *delay* in taking the offensive after the victory of Salamis had entirely changed the situation?

Where Mr. Grundy has seen with his own eyes he generally has something useful to say, but where he has not seen he cannot always be trusted. It is an absurd exaggeration to call the Taurus an "all but blank impassable wall"; and other references to it would certainly suggest that it runs north and south! The theory of the weak strategic situation of the Asiatic Greeks will not hold where any communication by sea is so much better than any by land as in western Asia Minor. Was it either land or sea that divided, *e.g.*, Samos and Miletus? For downright geographical nonsense it would be hard to beat the description of Pteria as "a town whose position renders it the chief strategic point in the Halys region, commanding, as it does, the middle portion of the cleft-like valley through which the river flows" (p. 15). Mr. Grundy does not appear conscious of all the difficulties which beset Xerxes' march through Thrace as conceived by Herodotus. They do not harmonise well with his doctrine that the historian had himself traversed the road.

In the early chapters, the author makes great play with the idea of the "Ethnic frontier." As applied to the Persian attacks on Greece this is no novelty; but will it explain the conquest of Thrace? Are Phrygians and Bithynians still to be called Thracians in the days of Darius?

The book is sumptuously got up. It is a pity that so many misprints have been overlooked. Some of these are very unfortunate, *e.g.* banaustic (p. 94), St. Demetrion (three times), Elataea (four times), Oeroe with initial diphthong (always). Xerxes on p. 69 ought to be Darius. On the map of Marathon, Kynossema ought to be Kynosoura. On p. 350, Mr. Grundy has interchanged *east* and *west*—did he "alter his point of view"? On p. 378, a whole paragraph is based on a childish mistranslation of Herodotus.

In conclusion, we must heartily thank Mr. Grundy for publishing the many exquisite sketches by Edward Lear. They are as accurate as they are beautiful, and even had this book no solid merits of its own to recommend it, they would suffice to make it valuable.

GEOMETRY ON THE SPHERE.

Spherical Trigonometry. By the late I. Todhunter, M.A., F.R.S. Revised by J. G. Leathem, M.A., D.Sc. Pp. xii + 275. (London: Macmillan and Co., Ltd., 1901.) Price 7*s.* 6*d.*

THIS volume gives a systematic treatment of the subject of spherical trigonometry, based on the sound foundation of Todhunter rearranged and amplified. While the merit of the original work is sufficiently indicated by its vitality, the preface bearing the date 1859, it is natural that a text-book designed for the use of students forty years ago should to some extent fail to satisfy the requirements of the present day.

The subject falls naturally under two heads, (1) Formulæ connected with the Spherical Triangle and the Solution of Triangles, (2) Spherical Geometry. In both departments the reviser has used skill and judgment in grafting fresh shoots on the old stock, and has produced a homogeneous and well-balanced volume, double the size of the original and worthy to take its place among the best of our modern text-books. In trigonometry proper, Todhunter's treatment has been rendered very full and thorough. The theory is illustrated by well-selected numerical exercises, fully worked out and presented in the most concise form with due attention to labour-saving devices. Critical and ambiguous cases are carefully considered, discussed and illustrated diagrammatically, while

the practical methods and terminology used in navigation receive some notice.

In the department of spherical geometry more extensive additions have been made. New chapters have been added on Properties of the Spherical Triangle, Properties of Circles on the Sphere, The Principle of Duality, Hart's Theorem, The Generalised Triangle, The Application of Determinants to Spherical Geometry, while some additions and modifications have been introduced elsewhere. The chapter on the principle of duality gives an excellent *résumé* of the subject, illustrated by the exhibition in parallel columns of corresponding properties of a co-axal system of circles on the sphere and its dual a co-lunar system. The principle is also utilised in what the reviser styles, in the preface, a new treatment of Sir Andrew Hart's very striking and fertile theorem that the inscribed and escribed circles of a spherical triangle touch a fourth circle besides the three sides of the triangle. The bearings of the principle of duality on Hart's theorem have, however, been already discussed, and Dr. Leathem's treatment does not seem to add much that is essentially novel. The proof of the theorem, as here presented, appears, indeed, to be open to objection; the proof in § 178 of the condition for the contact of a given circle with the circumcircle of a given triangle assumes that the circles have a *real* limiting point L, while in §§ 203 and 204 all that has been proved is that the cone joining the circle H to the centre of the sphere touches, internally or externally, the inscribed and escribed circles of the triangle—an appeal to the particular case of the equilateral triangle, without further discussion, in order to determine the nature of the contacts hardly carries conviction. The plane analogue of this mode of treatment of Hart's theorem may be found in Lachlan's "Modern Pure Geometry," pp. 206 and 250, where also an adaptation to plane geometry of the theory of duality on the sphere is given at p. 257. Needless to say, the subject admits of wide development.

Among the chapters devoted to spherical geometry, one dealing with inversion, stereographic projection, &c., would have been welcome, but it was possibly excluded by want of space.

In the new chapters admirable judgment is displayed in the selection and arrangement of materials from a wide range of original sources, numerous historical and bibliographical references forming an excellent feature of the work. The style throughout is clear and attractive, and most of the examples which have been added possess the merit of elegance and real scientific interest. A. L.

A CONSUL IN CHINA.

John Chinaman and a Few Others. By E. H. Parker. Pp. xx+380. (London: John Murray, 1901.) Price 8s. net.

THIS is an interesting book of personal reminiscences during a long official residence in China. Mr. Parker served in the consular service for many years at a time when our relations with the Flowery Land were even more precarious and uncertain than they are to-day, and it is interesting to observe how under these conditions, and with Sir Harry Parkes as our Minister at Peking, a spirit of self-reliance was engendered among all holding authority at the outlying ports. The riots directed against foreigners which are now occasional were chronic in the 'eighties, and Mr. Parker came into a fair share of them. Being ever ready to accept responsibility, he in most cases undertook the defence of his countrymen during the acute stages of the crises, and when the hurly-burly was over arranged with the local authorities for the necessary punishment of offenders and compensation for the destruction of property. As he remarks, after describing a serious outbreak at Wênchou,

"The moral of this story is that Chinese nerves are so constructed that every Mandarin seems to have in him the makings of a murderer or a saviour, accordingly as the tide in the affairs of men is taken at the flood or on the ebb; that rows are seldom so dangerous or so serious as their noise and appearance is (*sic*) appalling; and that a readiness to make allowances for foolish human nature is commonly appreciated at its full value on the Chinese side. The same missionaries had to take refuge on the island once more dur ng the Boxer riots of 1900, but I see that my sensible and accomplished successor has been able to abstract ample compensation in the same friendly spirit as that evinced sixteen years ago. I see no reason why the whole Chinese question should not be treated on analogous lines."

To the principle here involved we entirely agree, but, unfortunately, the whole Chinese question has to be settled, not by one plain-dealing man, but by a dozen plenipotentiaries whose interests are conflicting, and some of whom find in a disturbed China a prospect of the realisation of their best hopes.

Another source of diplomatic difficulty at the present time is the absence of sound statesmanship at Peking. In the 'sixties, as Mr. Parker points out, there were men like Prince Kung, Wên-Hsiang and Kui-Hsiang, who were giants in comparison with the Prince Chings of the present day. Sir Thomas Wade used to call Wên-Hsiang "the last of the Manchus," and it is difficult to point to another of the race who has risen to anything like the same level of wisdom and knowledge.

But Mr. Parker has much to say of the Chinese and their affairs outside the political arena. He mixed more with the natives and gained a better insight into their characteristics and peculiarities than most Chinese-speaking foreigners, with the result that he has much to say in their favour and many strange peculiarities to note. Among the latter he mentions the curious tendency there is among the people to commit suicide.

"Women are the chief delinquents, or heroines, as they often imagine; it only needs a harsh word or a fit of passion, when down goes an ounce of opium—a most comfortable death. It will be noticed that the recent Boxer troubles are responsible for the suicide of at least a score of prominent statesmen. In some cases whole families have dived head foremost into wells in order to share the master's disgrace or self-sacrifice. In others the Emperor has 'bestowed the cord'; which means that a man sits with his back to a panel and his friends strangle him through two holes. So far from being considered a crime, suicide is under many circumstances regarded as a noble act; rarely as a despicable one, unless done in pure spite, or out of revenge."

The position of women in China is well illustrated by the many stories the author has to tell of native life, and the conclusion at which he arrives is that on which all close

observers are agreed, viz. that they have much more power in their households than is generally supposed, and that their status is universally recognised by all heads of families who desire to lead quiet lives. Mr. Parker quotes the case of a Captain Ch'ên as an illustration of common official domestic affairs.

"He"(Captain Ch'ên) "had a wife—*passée* of course—who ruled the roast in that watchful and relentless way in which capable French women *d'un certain age* rule a busy café. Captain Ch'ên bought, sold, and exchanged concubines freely, this freedom evidently being the common basis upon which agreeable terms had been made between himself and his wife.... Like a sensible man, he always showed formal respect to his wife; and, although he never took her to the various forts, camps, and war junks in or on which he was from time to time employed for months at a stretch, he always consulted her; left the purse strings in her charge; and gave her feminine command over all the concubines and 'slaveys' not actually with him."

Mr. Parker evidently has the gift of tongues, and finds it equally easy to communicate with the natives of Peking, the Hakka people of Canton, and the speakers of half a dozen or more dialects throughout the Empire. In the present work we have the results of this polyglot ability, and in a succession of short chapters, or notes, he throws countless side-lights on the kaleidoscopic aspects of the Chinese question and the social life of the people.

OUR BOOK SHELF.

The Home-Life of Wild Birds. By F. H. Herrick. Pp. xix + 148. (New York and London: G. P. Putnam's Sons, 1901.) Price 10*s.* 6*d.* net.

IN this attractive and beautifully illustrated volume the author lays claim to having invented a new method of studying and photographing birds in their native haunts; and he is certainly to be congratulated on the success of his efforts. Although his method of working is somewhat different, Mr. Herrick may be said to have done for some of the commoner birds of North America what has been effected by the Messrs. Kearton for those of Britain; and higher praise than this it would be difficult to bestow. To the English reader the book will be especially welcome, as throwing a flood of light on the habits of species with which he is necessarily unfamiliar. Among the most successful of the author's efforts are his photographs of cedar-birds, or waxwings, with their nests and young, which illustrate in full detail the mode in which the nestlings are fed and tended by their parents, and the curious postures assumed by the latter in the course of their duties. The attention devoted by these birds to their offspring is well indicated in the following passage, where it is stated that, on one occasion, "with half-spread wings and with back to the sun the mother protected her little ones for a full hour from the broiling sun, while her mate came repeatedly and handed out the cherries."

Instead of photographing from a long distance, or with a camera placed near the nest and worked by the observer from a distance by means of a string, the plan adopted by the author is to bring the nest and its surroundings within a short distance of the observer, who is himself concealed. If the nest be situated on a branch at a considerable height from the ground, the bough is carefully cut off and fixed, with the nest, in its natural position near the ground in a good light. If, on the other hand, the nesting site be a tussock of grass in thick coppice, the whole mass is dug out and transplanted to the open. The photographer takes his station in a green tent, through a hole in the canvas of which the camera can be brought to bear on the nest and its surroundings. When the nest is in a situation to which the tent can be brought near, and where the light is good, its natural position is not interfered with, and only such boughs as obstruct the view are cut away.

It might be thought that the removal of a nest and its surroundings from a height of 40 feet to within a yard or so of the ground, or from the shade of a dense coppice to the glare of sunlight, would seriously disturb the parent birds. This, however, according to the author is not the case if proper precautions be taken. "No injury," writes Mr. Herrick, "is wrought upon old or young. The former nesting conditions are soon forgotten, while the new are quickly adopted and defended with all the boldness of which birds are capable."

The method is at present only in its infancy, but by its aid we may hope in time to have permanent records of the complete life-history of a large number of birds during their nesting-seasons.

Finishing the Negative. Edited by George E. Brown, F.I.C. Pp. 160. (London: Dawbarn and Ward, Ltd., 1901.)

ALTHOUGH there are many very excellent handbooks on photography in general, there are few which give so much useful and necessary information regarding the treatment of the photographic plate after the negative has been obtained. Many amateurs consider the negative ready for printing after a few spots have been obliterated and perhaps a small retouch here and there; but a glance at this book gives one the idea that the negative is by no means ready for printing, but may be improved (in the case of beginners probably not) by many of the numerous hints here brought together. The separate chapters of this book are devoted to the manipulations of drying, hardening, clearing and removing stains, different methods of intensification and reduction, softening and increasing contrasts, varnishing, stripping, retouching portrait negatives, handwork on back and front of negative, spotting and blocking out, and many other aids to producing a "perfect" picture, concluding with special hints for applying the above processes to the working of celluloid and stripping films.

The editor of the book tells us that in many of the chapters he has had the able help of several workers in these special lines of work, so that the reader will find the hints both practical and instructive.

The book will certainly fill a gap as regards the special branches to which it is devoted, and the many well-chosen illustrations considerably aid the text in showing the reader the "before" and "after" stages of many of the manipulations described.

Text-book of Elementary Botany. By Charlotte L. Laurie. Pp. ix + 142. (London: Allman and Son, Ltd., n.d.) Price 2*s.* 6*d.*

THIS little book supplies the information required for such examinations as the junior Oxford and Cambridge, and is specially adapted to a school curriculum. Despite some defects which are mentioned below, the author is to be congratulated on having written an elementary botany which shows some new features and by its character and conciseness avoids the dull level of most similar works. There is much that calls for favourable comment. The language is simple, and technical words are slipped in easily with derivation or other simple explanation; the illustrations are original, for the most part extremely good and well reproduced, and throughout the book an admirable balance is maintained—no easy matter when the compass is so small. There are three parts to the book, dealing with morphology, classification and physiology respectively. Very wisely, no attempt is made to treat of internal anatomy, so that all exercises can be worked out with the lens and scalpel. In the morphological part, useful summaries pick out at intervals the main data for description or comparison; also numerous ecological references are worked in. One must

regard the use of the terms "sporangium," "macrospore," "microspore" as unnecessary, seeing that the book deals only with the flowering plant; and why "oosphere" and not "ovum"?

In the second part short chapters explain the Linnæan and natural systems of classification, the distribution of plants, and give general directions for field work.

The physiology is the least satisfactory part of the book. The plan adopted of giving experiment, result and conclusions to be deduced therefrom is eminently good. But many of the experiments are open to serious criticism, as in some cases the apparatus is not practical, in others the deductions are unsatisfactory. For instance, apparatus is figured on p. 126 to show that plants take in oxygen. The apparatus shown would certainly allow leakage of air; the potash would not absorb much carbon dioxide, and in so far as it did, this would partly account for the change in the manometer; further, the seedlings shown in the figure would photosynthesise unless placed in the dark. The three subsequent figures also show apparatus which is not workable. Despite these faults and one or two erroneous statements, the book is so vigorous and well compounded that it may be strongly recommended to school teachers as one which is eminently suitable for beginners in botany.

Intuitive Suggestion. By J. W. Thomas. Pp. x + 160. (London: Longmans, Green and Co., 1901.) Price 3*s*. 6*d*. net.

IT is difficult to know how far Mr. Thomas takes himself seriously. His book is called a "New Theory of the Evolution of Mind," and certainly contains some very novel and curious statements both about the past and about the future of mankind. He has, however, no very clear notion of the difference between saying a thing and proving it, and many of his most remarkable assertions are made without any serious attempt of proof. His main thesis appears to be that the processes of the inorganic and organic worlds alike are the consequences of a series of quasi-hypnotic "suggestions" on the part of a "great first cause." He takes, that is, a few unfamiliar and very imperfectly understood facts of experience and makes them the basis of a theory of experience as a whole. Apparently he has never even asked himself whether there is any evidence to show that a creature without a nervous system would be amenable to "suggestion" at all. The argument from the miraculous narratives of the Bible, on which he lays great stress, is deplorable alike from the standpoint of logic and of piety. From the logician's point of view, the alleged facts are insufficient as a basis for a theory of nature, and from that of the believer they lose all their moral significance by being degraded to the level of mediumistic or hypnotic "phenomena." A. E. T

Jahrbuch der Chemie. Herausgegeben von Richard Meyer. Jahrgang, 1900. Pp. xii + 565. (Brunswick: F. Vieweg und Sohn.) Price 15 mk.

THOUGH somewhat later in the time of its appearance, this valuable publication is happily not much thicker than its precursors, and the volume before us gives in reasonable space an excellent summary of the chief advances in chemistry and applied chemistry recorded in the year 1900. The labour of writing is distributed among authorities of the highest competence, and the result is correspondingly satisfactory. It is true that the information is in a highly condensed form, but the present writer is able to say of the subjects on which he is at all qualified to speak that they are dealt with in summaries which bear the impress of informed writers rather than hack abstractors, and that they will continue to serve well the useful purpose of assisting all those who are engaged in the difficult task of keeping themselves moderately well informed of chemical progress.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Earthquake Observations in Strassburg.

DURING the last twelve months, on more than one occasion I have been asked why it is that at the Kaiserlichen Hauptstation für Erdbebenforschung in Strassburg one type of instrument records earthquakes so very much more frequently than other types of instruments give records, although they are all installed in the same building. An answer to this is apparently to be found in an analysis of the Strassburg registers.

For example, in January 1901, a von Rebeur-Ehlert apparatus, which consists of three horizontal pendulums oriented at 120° to each other, which reflect beams of light on to a photographic recording surface at a distance of about three metres, yielded twelve records, only five of which were noted by a single component horizontal pendulum of the type adopted by the British Association and now in use at very many stations round the world. This latter apparatus was therefore quiescent on seven occasions when we should have expected it to have been in action. On looking at the registers, we first observe that these seven disturbances were all exceedingly small, and two of them were only noted in Strassburg. Considering this latter fact, in conjunction with the facts that they are found in the traces from an instrument with a very high multiplication, subject to so-called "Mikroseismische Unruhe" (air tremors?), and that a blur may be formed in the photographic record by a slight flare in the illuminating apparatus, it seems a bold proceeding to enter such records (January 17 and 26) as being earthquakes. I doubt their seismic character and consider that their entry ought to have been accompanied by some qualification. So much for two out of the missing seven. Two others (January 8 and 30), although not recorded by the British Association type of instrument in Strassburg, were recorded by similar instruments in Britain and at stations in other parts of the world. That they were not recorded in Strassburg, but were recorded all round Strassburg, suggests the idea that the instrument as installed at the Hauptstation has not the desired amount of sensibility, and if this is the case it is not remarkable that this form of instrument as used in Strassburg should fail to record very small earthquakes.

As another illustration let us take the month of August, when the Rebeur-Ehlert pendulums gave twenty-four records, out of which the British Association seismograph is advertised as only having responded to four. A glance at the registers for stations in Britain and other countries shows that this number should be increased to seventeen, leaving a balance of seven, which, if they all are earthquakes, are for the most part peculiar to Strassburg, and as such have in my own mind a doubtful character.

Another point connected with the Strassburg registers relates to the determination of origins. To identify a seismogram obtained at Strassburg on September 17 at 4.30 a.m. as connected with an earthquake which shook a small portion of the north of Scotland at about 1.25 a.m. on that morning is asking us to believe more than our reason can accept. Even had the Hauptstation been situated in the south of Scotland itself, it is very doubtful whether its horizontal pendulums would have responded to a local shock originated in the northern part of the same country. JOHN MILNE.

March 3.

Proofs of Euclid I. 5.

SEVERAL writers have lately expressed their opinions in favour of replacing the present proof of this proposition by an alternative proof based on the supposition that the bisector of the vertical angle of the isosceles triangle is drawn, irrespective of the fact that no construction has been given for drawing this bisector. Now there may be some advantage in using a "hypothetical construction" to prove a proposition, where its avoidance necessitates a long and tedious alternative proof. In the present instance the artifice is absolutely unnecessary, as the proof can be simplified in any of the following ways, A being the vertical angle of the isosceles triangle ABC:—

(1) By adopting Euclid's construction of cutting off equal segments AD, AE from the sides and proving as he does that the triangles ABE, ACD are equal in all respects, and then making D, E coincide with A, B respectively. The method of passing to limiting cases is highly instructive, the only question being as to the advisability of trying to introduce it to beginners, except as an experiment.

(2) By drawing a duplicate DEF of the triangle ABC (this operation being only a slight extension of the method of superposition used by Euclid in I. 4), and proving first that $\angle A = \angle E$ and $\angle B = \angle F$, and second that $\angle A = \angle F$ and $\angle B = \angle E$.

(3) By *folding the triangle* so as to bring AB into coincidence with AC. This is *practically* equivalent to bisecting the vertical angle, but it replaces a "hypothetical construction" by an operation which the beginner can easily perform.

The method of folding has many obvious advantages, and much would be gained if beginners could be taught at once to recognise cases in which one half of a figure could be brought into coincidence with the other half by folding. For example, the property that the common chord of two circles is bisected at right angles by the line joining the centres is obvious when it is recognised that one half of the figure is the fold of the other half. The method is, moreover, hardly more artificial than the method of superposition which Euclid himself employs.

It should be noticed that Euclid's proof of I. 4 involves an assumption which I have never seen pointed out, namely, that *two straight lines cannot touch one another*. If this be not assumed, then when the sides DE and AB are brought into coincidence, the sides DF and AC do not necessarily coincide even though they make the same angle with the same straight line and on the same side of it. G. H. BRYAN.

The Zodiacal Light and Sun Pillars.

THE appearance on clear evenings of the zodiacal light *after* sunset at this season of the year in this latitude is usual, and it has been frequent and beautiful to observe in this district for many nights. It would be interesting if the readers of NATURE could detect any definite movement of the arm of light, for much yet remains to be discovered about this phenomenon, and any observer can make this point a study. From a short half-hour after sunset to from 8 to 9 p.m., a straight line drawn from the sun's position at sunset to the Pleiades will not remain the centre line of the zodiacal light. It appears to emanate from the sun and move as the luminous spoke of a wheel which has the sun for centre frequently, but not invariably. What makes the light apparently fade away? Is it that the motion of the earth has drawn with it the arc of volcanic or meteoric particles, which may be the medium of the light, away from the sun? or is it not possible that such a band of dust is lit with a degree of earth-shine? If so, may not this account for that other phenomenon of the Gergershein, which is usually brilliant in proportion to the brilliancy of the zodiacal light? Doubtless these phenomena are always present, but their visibility depends on the magnetic or electric condition of our atmosphere. Irritated by either of these conditions, the belts of dust would alter positions of all the bodies forming them, and so lie at a different angle and be clearer or dimmer accordingly.

The very remarkable sunset of March 6 has probably been observed by many readers of NATURE. The "fire-finger" left in a perfectly perpendicular position for upwards of fifty minutes after sunset was visibly withdrawn, without losing colour or size or changing from the perpendicular, and was a vivid and beautiful adjunct to a sunset afterglow strangely reminding one of the "Krakatoa sunsets" of years ago. This finger of fire the writer has only observed once before, after a similar-coloured sunset over the estuaries of the Medway and Thames last summer, but London smoke dimmed the effect. This rare appearance seemed on March 6 to resolve or be replaced by five vivid *white* rays with slight wheel motions from north to south, the largest of which eventually seemed the zodiacal light itself.

GUY J. BRIDGES.

Sutton Mandeville Rectory, Salisbury.

A PHENOMENON was visible here this evening which I think deserves to be recorded. We have an uninterrupted view of the western sky, and about a hundred pairs of sharp eyes are available, so that any unusual sunset is pretty certain to be noticed. Solar halos are comparatively common occurrences, and I have come to the conclusion that lunar rainbows are not so rare as is believed, but the "pillar of fire" which has been visible here for at least forty minutes is the most brilliant sight I or any of my oldest friends have ever witnessed. It was first observed at 6 p.m. just after the sun had disappeared, and was exactly *vertical* over the sun. The colour was at first silvery (resembling a searchlight) and later a golden yellow, the width equal to the sun's diameter, and the length 18° to 20°. A few light clouds seemed to pass *behind* it. Some observers noted a flickering and also a swaying motion, but this may have been an optical effect. At about 6.30 the colour had changed by gradations into a deep crimson-red, and for the next ten minutes it gradually became deeper in colour and shorter, disappearing at 6.40.

I may add that on February 20, 1901, I observed a very faint trace of a similar phenomenon.

Can any of your readers direct me to any literature bearing on the matter? WM. A. KNIGHT.

Sexey's Trade School, Bruton, Somerset, March 6.

The Quadrantid Meteors.

MR. JOHN R. HENRY, according to his letters in NATURE of January 2 and 23, unfortunately looked out too late for the Quadrantids, owing to having miscalculated the time of maximum, the approximate probable time of which might also have been obtained from the British Astronomical Association. He is right in saying that the date of the shower is advancing into the year, but the advance is slower than he thinks. Taking the data he gives, which, however, are only very rough, and also a consideration of the sun's longitude as given in the "Nautical Almanac," there is an advance of only five hours in the thirty-seven years 1825 to 1862. It would appear that in the forty years from then a further advance of probably about eight hours has taken place. It is unfortunate that Prof. A. S. Herschel has not published the exact number of meteors he saw from hour to hour on January 2, 1900, when he watched from 11h. to 16h. 30m. He, however, states that the frequency continued about the same during the whole period, and seeing the radiant point was rising all that period, this would mean that the maximum was near the beginning of his watch.

Mr. Henry may be right in saying that the period of maximum fluctuates somewhat from year to year, though the data he gives are not sufficiently accurate to prove this; but I fail to see what ground he had for expecting the maximum so late as he did this year. Taking all the data into consideration, we might have expected the maximum to be about 23h. on the 2nd. I see no reason to doubt that this expectation was fulfilled; but as the maximum would occur in the daytime, observations in other countries would be necessary to prove this. The Quadrantids as seen here were most numerous on that morning.

It seems probable, therefore, that the time of the next maximum will be about 5h. on January 3, 1903. T. W. BACKHOUSE.

West Hendon House, Sunderland, March 5.

Elementary Mathematics.

I WAS very glad to read in NATURE of January 30 (p. 297) the letter of Mr. J. W. Marshall on elementary mathematics, because all his suggestions referring to elementary algebra have already been realised in my book, "Applied Algebra," published in 1900 at St. Petersburg, in Russian.

I send, therefore, two copies of my book, one for the editor, the other for Mr. Marshall. The algebraical characters will permit every mathematician to judge somewhat of the character of a mathematical book without a knowledge of the Russian language. My compatriots have already condemned my heresy; but I hope that my ex-compatriots (our family is of Scottish origin, derived from Lehrmouth) will judge more liberally my attempt to improve the old method of teaching the prolific science of algebra.

The peculiarities of my exposition are explained by the fact that I wished to say all that was needed, and only what was needed. For that purpose it was necessary to put in the first place the systematical exposition of all the most fundamental methods of algebra which are sufficient for ordinary applications, and to postpone to a supplement all complicated questions that are usually combined with fundamental notions in the existing manuals, only producing a confusion in the minds of the pupils.

Before attempting to expound a new section, I endeavour to explain the purpose which this section serves, for as King Solomon stated: "A fool hath no delight in understanding, but that his heart may discover itself." (Prov. xviii. 2.)

In small type I have given many of the explanations that a good teacher requires with his pupils in the class room, but never includes in his printed manual. This peculiarity makes my book useful for self-instruction.

The beginning of all mathematical study is easy. The difficulty begins later, because it is indispensable to know what has already been studied for the understanding of what follows. Therefore my arrangement permits even the youngest pupils to learn something applicable to the practice of calculation.

WALDEMAR LERMANTOFF.

University of St. Petersburg, Russia.

THE NATIVE QUESTION IN SOUTH AFRICA.[1]

It cannot be too often repeated or too strongly impressed on the public mind of this country that by far the most difficult problem of South Africa is, not that of the relations of the white populations to one another, but that of the relations of the white population to the "Natives," and of the Natives to one another. It involves questions not to be solved by any process of patching. The ordinary "short view" recommended by European statesmen in treating European problems will not do. To deal with these questions effectually, considerations of a far-reaching economic and anthropological character are necessary. We must understand the Native mind, we must endeavour to see things from the Native point of view, we must consider the Native prejudices and aspirations as well as what we, from our point of view, regard as the Natives' best interests, and we must take into account their physiological and mental condition, and the influence upon it of the changes which have begun and the further changes impending.

It is thus evident that, before any final steps can be taken, a full inquiry into these matters must be held. Until the end of the war such an inquiry would be difficult. Consequently, all that can be done at present is to legislate on the most urgent points, so as to obtain a temporary *modus vivendi* on the labour contracts and the liquor laws. This is all that Lord Milner has yet attempted. But his despatches to the Colonial Secretary, and the important memorandum by Sir Godfrey Lagden, comprised in the papers recently presented to Parliament, though relating chiefly to the proclamations on the two subjects just mentioned, disclose the fact that the authorities are not insensible to the wider principles which must underlie our future policy. Lord Milner fully recognises the need of uniformity throughout British South Africa, and looks forward to a Native code to be framed by a Federal Parliament. It is satisfactory to learn from him that "the best colonial sentiment" as to our treatment of the Natives "is not far removed from the best home sentiment, as represented, for instance, by temperate and reasonable advocates of Native rights," such as the authors of "The Natives in South Africa," reviewed in these columns last May. What is wanted is that such sentiment should be controlled and directed by full and accurate information.

The Anthropological Institute and the Folklore Society have already petitioned Mr. Chamberlain to order a full and systematic inquiry into the Native laws and customs in our new colonies at the earliest possible moment. The authors of the book just referred to, whom Lord Milner mentions with so much approval, speak of the want of such an inquiry as "urgent." It is the only satisfactory way to provide the information required for the guidance of public sentiment, and of the administration; and if the example of Cape Colony be of value, it must precede any comprehensive attempt at legislation. The readers of NATURE are primarily interested in its scientific aspect. It is needless to reproduce the arguments they have had before them more than once. Those arguments are reinforced by Lord Milner's protests against some of the statements made on behalf of the Anti-Slavery Society and the Aborigines Protection Society in these papers, and by Sir Godfrey Lagden's admission that "there is much yet to be learnt by those who are vested with the control of Native affairs." And, though there is no allusion to the matter in the despatches now printed, we may be allowed to indulge the hope that it will not be overlooked as soon as the country is sufficiently pacified to enable the Government to arrange for it. Meanwhile, every opportunity should be taken by scientific anthropologists and jurists to bring their views before ministers and members of Parliament.

[1] "Transvaal. Papers relating to Legislation affecting Natives in the Transvaal." Presented to Parliament, January 1902.

THE JUBILEE OF THE AUSTRIAN METEOROLOGICAL CENTRALANSTALT.

To celebrate the fiftieth year of the existence of the Central Institute for Meteorology and Earth's Magnetism, the Vienna Academy has published a jubilee volume,[1] the contents of which form a very valuable contribution to science and an appropriate publication for this important celebration. This Central Institute, which is now the hub of all the meteorological and magnetic work carried on in the Austrian Empire, came into existence on July 23 in the year 1851, and it was founded with the object, first, of coordinating a number of stations all over the country and making them work on a uniform plan, and, second, of collecting such observations. How well these two objects have been carried out is familiar to every meteorologist of to-day, and so successful an issue of this organisation has been due to the consecutive labours of such directors as Kreil, Jelinek, Hann and Pernter, who have kept the Institute in such an excellent state of efficiency.

In the present volume we are first made acquainted with a brief history of the events which led up to the formation of the Institute, and the progress made during the period of office of each director. This is written in the form of an introductory chapter by the present director, Prof. Pernter. It is interesting to read that in the year 1851 Director Kreil had only forty stations working on a uniform plan carefully prepared by the Institute, but eleven years later he had increased the number nearly threefold. At this early stage there was a great amount of work to be accomplished, and Kreil, among other things, brought out the useful and valuable year book which was considered at the time a "modèle a suivre." The collection of old observations formed an important duty at this period of the Institute's history, and the first few volumes published contained long series of valuable observations made at Wien (1775–1850), Mailand (1763–1850), Prag (1775–1851), Kremsmünster (1763–1851), Salzburg (1842–1851), Udine (1803–1842), Fünfkirchen (1819–1832), Stanislau (1839–1850), and several other stations.

As time went on, the Institute, like many others, began rapidly to accumulate more work than it could accomplish, and this necessitated an increase in the staff and a greater output of publications. By the year 1877, 238 stations were sending in their results, while twenty years later this number had increased to 447; last year the number of first, second and third class stations together was 420.

To come now to the series of valuable articles which form the substance of this large volume, it may, in the

[1] "Denkschriften der kaiserlichen Akademie der Wissenschaften." *Mathematisch-Naturwissenschaftliche Classe*, vol. lxxiii.

first place, be remarked that as these cover no less than 600 pages, only a very brief reference can be made to each of them.

The first contribution, by the distinguished late director of the Institute, Hofrath Julius Hann, is a masterly discussion of the meteorological observations made at the Institute during the years 1852–1900. This paper brings together the monthly and yearly means of each of the meteorological elements during this period, and in two cases—namely temperature and rainfall—the data given extend back to 1775 and 1845 respectively. Such a long series of temperature observations has enabled him to investigate them for secular variations, with the result that he has found the anomalies to conform to a variation having a period of thirty-five years. It may be of interest here to mention that quite recently Hann has shown (*Kais. Akad. d. Wiss.* Jahrg. 1902, No. 1, p. 5) that the rainfalls of Mailand, Padua and Klagenfurt have also a secular variation of thirty-five years, the years of maxima and minima corresponding with Bruckner's epochs.

Next follow two papers relative to the "Föhn." The first is by Dr. Paul Czermack, in which he describes some experiments that serve to illustrate details in the behaviour and appearance of these currents. The second communication, by Dr. Robert Klein, deals with the daily variation of the meteorological elements at Tragoss due to the occurrence of the "Nordföhn," and he finds that all the elements are regularly disturbed by it, and offers an explanation for these variations.

The influence of the "Bora" on the daily period of some of the meteorological elements is discussed by Herr Eduard Mazelle. The observations were made during the years 1886–1895 at the astro-meteorological observatory in Trieste, and the results indicated that the elements changed definitely on these occasions.

A comparatively short paper, by Dr. Victor Conrad, describes the experiments and observations that he has made to investigate the water capacity of clouds and mists. In the first instance he devoted his time to the study of the "aspirationsmethode," producing artificial mists by means of a small boiler. The author then applied this method to natural clouds and mists, making his observations at elevated stations such as Schneeberg, Waxriegel (1884m.), Schafberg (1798m.), and Hohen Sonnblick (3106m.). The results are a distinct advance on earlier determinations, and, in addition, serve to explain some anomalies previously observed by other workers; thus, to take one case, the curve illustrating the relation of the water capacity to the "seeing distance" (in the mist) in metres shows clearly the difficulty of measurement of the water capacity when the seeing distance reaches about 150 metres.

We come now to two papers dealing with the daily variation of the temperatures in Austria and at Vienna (Hohe Warte), by Drs. J. Valentin and Stanislav Kostlivy respectively. Both these communications are exhaustive investigations on these meteorological elements, but even a brief reference to them must be omitted.

Dr. J. Pircher is the author of an important memoir on the hair-hygrometer. He first discusses the hair from the point of view of a hygroscopic substance, and describes in detail the features and peculiarities of different hair-hygrometers. This is next followed by a minute experimental investigation of the hair-hygrometer and its capability of indicating efficiently the phenomena it is intended to record. Comparisons of the hair-hygrometer with the condensation hygrometer of Alluard, with the psychrometer, the aspiration psychrometer of Assman, &c., are then given, concluding with deductions as to the sensitiveness of the hair-hygrometer and the influence of the action of direct sunlight upon it.

Some of the results at which the author has arrived, to put them in a few words, are, that the relative humidity can under all circumstances be measured to within five per cent., but in most cases to three per cent.; that the efficiency of the instrument is considerably decreased if it be allowed to stand for a long period of time in a room of constant humidity, it being pointed out that it is not only advisable, but necessary, to occasionally moisten the hair; and, finally, that temperature (with the exception of direct sunlight) and wind velocity have no effect on the instrument, while no variation was observed in the case of pressure.

A valuable paper by Prof. J. M. Pernter gives the results of some interesting experiments on the polarisation of light in cloudy media and their connection with the present explanation of the blueness of the sky. This investigation was undertaken to answer, if possible, the question whether the light of the sky (Himmelslicht) considered as scattered light of a cloudy medium, and the blue of the sky (Himmelsblau) as the colour of a true medium, could be more easily and, perhaps, also finally answered by the behaviour of light in relation to polarisation than by measurements of the intensity of single colours, since the latter, both with artificial cloudy media and with skylight, are connected with great experimental difficulties. Prof. Pernter used for the media different percentages of liquids coloured in such a way that he could employ all gradations of colour from the finest blue to a tone of milky white. Through these liquids he allowed rays of different colours to pass, and examined them after transmission by means of a polarimeter. In the summary of the results arrived at it will be seen that an important step in advance has been made from the experimental standpoint, and the observed facts are in harmony with the well-known theory of Lord Rayleigh.

The last two papers in the volume, which can here only be referred to by their titles, are written by Drs. Max Margules and Wilhelm Traberto, and are on "The Value of Work (Arbeitswert) of a Pressure Distribution and on the Preservation of Pressure Differences" and "Isotherms of Austria" respectively. In the latter the author has used, whenever possible, the fifty-year means of temperature, and has employed the values obtained from 773 stations in Austria and 142 outlying places; the maps accompanying the paper illustrate the isotherms for the months of January, April, July and October, the isotherms for the whole year, together with four other maps showing the isotherms for special regions.

In bringing this necessarily brief digest of the contents of this important volume to a conclusion, one cannot but call to mind the very valuable service this Central Institute of Meteorology has rendered to meteorological science in general. The numerous voluminous publications which have issued from its doors, and the very able help it has provided and still provides in many directions, are sufficiently well known to indicate the great activity that is displayed in its various departments. The publication of the volume before us is not only a fitting outcome of such labours, but is a worthy tribute to the memory of those who have striven to place the Institute in the first rank, in which it stands to-day.

W. J. S. L.

THE OWENS COLLEGE JUBILEE.

ON March 12, 1851, the Owens College began its existence in a modest house in the centre of Manchester which had formerly been inhabited by Richard Cobden. The College was removed to its present site in Oxford Street in 1873; since that date one addition after another has been made to the buildings, which now cover an irregular area of some 240,000 square feet.

The chemical laboratories have been twice enlarged,

notably in 1895 by the addition of the Schorlemmer laboratory; the engineering laboratory was opened in 1887 and has been greatly enlarged since; the large Beyer biological laboratories and the museum buildings were completed in the same year; the medical school was extended in 1883 and doubled in size in 1894; the Christie library was opened in 1898, the new physical laboratories (on a separate site) in 1900.

The Prince of Wales inaugurated the jubilee ceremonies of the College yesterday by opening the noble Whitworth Hall, which completes the large quadrangle of the College. It will be remembered that the late Sir Joseph Whitworth left the bulk of his fortune to Lady Whitworth, Mr. R. C. Christie and Mr. R. D. Darbishire, with absolute discretion as to the disposal of the money; of this more than 120,000*l.* has been given to Owens College by the legatees, jointly or severally. The late Mr. Christie, himself for many years a professor at Owens, after presenting the College with a beautiful library building from his private purse, gave in 1897 the residue of his share of the Whitworth bequest, amounting to about 50,000*l.*, for the building of a college hall, to be named after Whitworth. This hall, designed like the rest of the main buildings of the College by Messrs. Waterhouse and Son, is in the Gothic style, and is 120 feet long and 50 feet wide. It has a beautiful and elaborate high-pitched oak roof, of which the apex is 56 feet from the floor. The principals are supported on columns of granite. The sides of the hall are of polished stone with a panelling of polished oak. At the north end is an organ (the gift of Mrs. Rylands), encased in a fine screen of carved oak, and on a level with the organ loft, and adjoining it, are galleries for a choir. Immediately in front of the organ is a daïs, a few feet above the level of the floor. The hall is lighted by a series of stained glass windows on either side, and by a great window, in the perpendicular style, at the south end, in which the arms of the founder of the College and its chief benefactors have been inserted. The floor slopes slightly upwards from north to south, and at the extreme end of the hall there is a raised platform so that all can see the north daïs. Two small galleries are placed across the south corners of the hall, each adjoined by a short lateral gallery. The hall itself seats between nine hundred and a thousand persons. It forms the first story of the Whitworth building, of which the basement contains smaller rooms, destined for university offices, &c. There are exits into the museum and library, and also three exits on to Oxford Street and Burlington Street.

The order for the proceedings for the jubilee was as follows:—

Wednesday, March 12, 11.30, commemoration of the foundation of the College and opening of the Whitworth Hall, by H.R.H. the Prince of Wales (accompanied by H.R.H. the Princess of Wales); 2.15, luncheon at the Town Hall by invitation of the Lord Mayor of Manchester, and at the College by invitation of the College authorities; 8.30, reception at the College, by the president, the Duke of Devonshire, K.G., and council.

Thursday, March 13, 11.0, presentation of addresses of congratulation from universities and learned societies in the Whitworth Hall and conferring of honorary degrees by the chancellor of the Victoria University, Earl Spencer, K.G.; 7.30, dinner given by the College to delegates and to the governor and staff of the College.

Representatives from a number of foreign and colonial universities and learned societies arranged to be present, among them being the following:—Foreign universities and societies: Paris, Prof. A. Espinas; Lille, Prof. A. Angellier; Académie des Sciences (Institut de France), Prof. H. Becquerel; Munich, Prof. Hermann Breymann and Prof. K. Goebel; Göttingen, Prof. Walther Nernst; Göttingen (Royal Academy of Sciences), Prof. Voigt; Lund, Mr. Vice-Consul H. Ehrenborg; Geneva, Prof. Chodat; California, Prof. F. Slate; Western Reserve (Ohio), Prof. H. E. Bourne; Zürich Polytechnic, Dr. E. Knecht. Indian, Colonial universities and learned societies: McGill (Montreal), Lord Strathcona, G.C.M.G. (High Commissioner for Canada); Calcutta, Dr. William Booth; Bombay, Sir J. Jardine, K.C.I.E.; Madras, Mr. J. B. Bilderbeck; Cape of Good Hope, Mr. T. E. Fuller (Agent-General for Cape Colony); Adelaide, Prof. Hudson Beare. In addition delegates were sent by the universities of the United Kingdom, university colleges, and most of the learned societies.

It may be mentioned that at the opening of the College among the members of the staff, which consisted of a principal, four other professors and two teachers, were Archibald Sandeman, professor of mathematics; Dr. Edward Frankland, professor of chemistry; and W. C. Williamson, professor of natural history, botany and geology. There were sixty-two students in the first session. The staff now consists of the principal, Dr. Alfred Hopkinson, and thirty-one other professors and eighty lecturers and assistant lecturers; and the College has between a thousand and eleven hundred students in its various departments of arts, science, law and medicine.

NOTES.

WE regret to see the announcement of the death of Prof. Maxwell Simpson, F.R.S., formerly professor of chemistry in Queen's College, Cork, at the age of eighty-seven; and also of Mr. Bryan Donkin, a vice-president of the Institution of Mechanical Engineers, at the age of sixty-seven.

PROF. J. KUEHN, professor of agriculture in the University of Halle, has been elected a correspondant of the Paris Academy of Sciences, in the section of rural economy.

THE Raoult memorial lecture of the Chemical Society will be delivered by Prof. van 't Hoff on Wednesday, March 26, in the lecture theatre of the Royal Institution. The annual general meeting of the Society will be held on the afternoon of the same day.

AN interesting Easter excursion to the Gower Peninsula, South Wales, has been arranged by the Geologists' Association. The party will leave London on Thursday, March 27, and will return on Wednesday, April 2. The district is rich in fine rock scenery, instructive exposures and cliff sections, and splendid views, so that those who are able to take part in the excursion may be assured of a pleasant holiday.

THE Paris Natural History Museum celebrated on Sunday last the fiftieth anniversary of the publication of the first scientific memoirs of one of the most distinguished members of its staff, M. Albert Gaudry. He was honoured, says the Paris correspondent of the *Times*, as one of the most eminent evolutionists in France, in many respects a precursor of Darwin. It is he, in the words of M. Edmond Perrier, the director of the museum, who has virtually emancipated palæontology from the swaddling clothes in which its mother science, comparative anatomy, had endeavoured so long to keep it.

PROF. MELDOLA'S address on the coming of age of the Essex Field Club, which will be given at the twenty-second annual meeting, to be held in the Essex Museum, Stratford, on Saturday, March 22, should be worth the attention of those interested in naturalists' societies or desiring to encourage their efforts. A carefully digested record of the *local* scientific work carried on by the

Club and its members will be of great value. Since its foundation in 1880, the Society has published about 5000 pages of matter, three-fourths of which relates to the natural history, in the widest sense, of the county of Essex, and much of it is wholly original in character. Any reader desiring to attend the meeting should communicate with the hon. secretary, Mr. W. Cole, Buckhurst Hill, Essex.

A MEETING of the American Philosophical Society will be held at Philadelphia on April 3–5. Among the subjects of papers included in the preliminary programme are:—The International Catalogue of Scientific Literature, Dr. Cyrus Adler; recent progress in the lunar theory, Prof. E. W. Brown, F.R.S.; systematic geography, Prof. W. M. Davis; results of observation with the zenith telescope at the Sayre Observatory, Prof. C. L. Doolittle; the advancement of knowledge by the aid of the Carnegie Institution, President D. C. Gilman; the continuity of protoplasm, Prof. H. Kraemer; further experiments on the physiological action of ions, Dr. Jacques Loeb; wireless telegraphy, Mr. Guglielmo Marconi (if in America); distribution of fresh water decapods and its bearing upon ancient geography, Dr. Arnold E. Ortmann; evolution and distribution of the Proboscidea in America, Prof. H. F. Osborn; the relation of the American University to science, President H. S. Pritchett; South American mammals, Prof. W. B. Scott; historical investigation of the supposed changes in the colour of Sirius since the epoch of the Greeks and Romans, Dr. T. J. J. See; and biological heredity and organic evolution, Prof. Giuseppe Sergi.

THE ninth meeting of the Australasian Association for the Advancement of Science was held at Hobart on January 8–16, under the presidency of Captain F. W. Hutton, F.R.S., whose address on evolution and its teaching was abridged in last week's NATURE. The presidents of the sections and the subjects of their addresses were as follows:—Mr. R. W. Chapman (astronomy, mathematics, physics and mechanics), tidal theory and its application; Prof. A. M. A. Mica-Smith (chemistry and mineralogy), the study of the chemistry of the air, and whither it has led; Prof. T. S. Hall (geology and palæontology), the possibility of detailed correlation of Australian formations with those of the mother hemisphere; Prof. W. B. Benham (biology), earthworms and palæo-geography; Rev. Geo. Brown (geography), the Pacific, east and west; Mr. T. A. Coghlan (economic and social science and statistics), the statistical question; Dr. W. E. Roth (ethnology and anthropology), on the games, sports and amusements of the North Queensland aboriginals; Sir T. Fitzgerald (sanitary science and hygiene), the nature of diseases; Prof. A. Wall (mental science and education), poetry as a factor in education; Mr. P. Oakden (architecture and engineering), no title announced. Many papers were read in each of the sections, and from the titles in the official programme we judge that a large proportion was of wide scientific interest. The handbook prepared for the use of the members contains a short historical sketch of Tasmania, and essays on the natural history of the country. These signs of scientific activity at the antipodes are of interest to those who regard contributions to natural knowledge as essential to the development of national character and progress.

PROF. W. R. DUNSTAN, F.R.S., director of the scientific department of the Imperial Institute, presided on March 4 at the first of a series of six lectures and demonstrations which are being given at the Institute by Mr. R. Hedger Wallace, formerly of the Victorian Agricultural Department, on "The Commercial Products and Agricultural Resources of the Crown Colonies." In his introductory remarks, the chairman explained the object of the course. The Imperial Institute contains magnificent collections of products, illustrative of the natural resources of the colonies, and it is hoped that by lectures and demonstrations such as these the interest and utility of the collections to the general public will be much increased. Following each lecture, Mr. Wallace will give a demonstration in the particular court containing the products of the colony described. A large and increasing number of schools throughout the United Kingdom have applied to the Imperial Institute for small collections of various colonial products, and it is therefore hoped that this course will attract both teachers and pupils. Mr. Wallace began by directing attention to the fact that the value of the imports and exports of Great Britain last year was 522,000,000*l*. and 280,000,000*l*. respectively. It is a matter of importance, therefore, to ascertain whether this adverse balance of 242,000,000*l*. passes to the British planter and manufacturer, and remains within the Empire, or goes to foreign countries. Hence also the desirability of ascertaining what can most profitably be grown in our various colonies. From this point of view England has much to learn from Germany. That country has recently sent out scientific experts to report on the natural resources of its colonies and to ascertain by practical experiment how capital can be most profitably invested. In England, on the other hand, this matter is left largely to private enterprise.

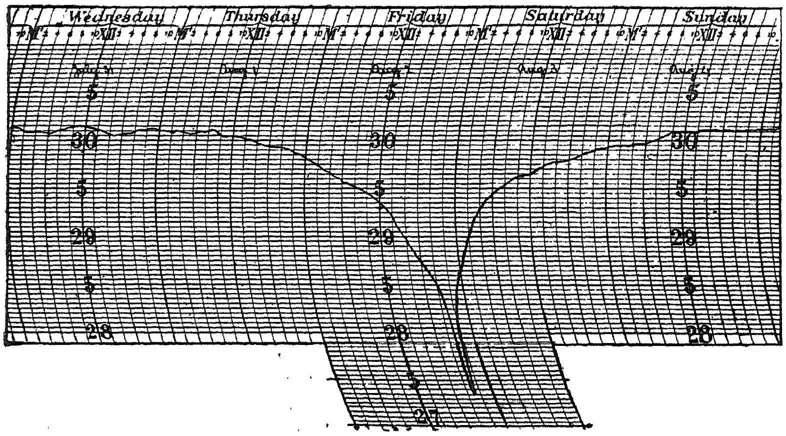
THE influence of mountains on the fall of hail has frequently been the subject of controversy, but up to the present time no certain conclusion appears to have been arrived at. The Italian Meteorological Office has recently published an interesting note upon the question by Prof. V. Monti. The positions chosen were perhaps the most suitable for the purpose of any among the Italian network of stations, viz. the Collegio Romano and Montecavo, an isolated station near Rome, situated at an altitude of about 1000 metres; the complete observations at both stations, for the years 1880–87, are contained in the *Annals* of the Italian Meteorological Office. During this period, forty-one days of hail were recorded at Rome against eighty at Montecavo; the monthly values show two maxima, in April and October, and two minima, in July and December, as regards the excess of days of hail at the mountain station. A comparison of days of thunderstorm shows, on the other hand, that there were 176 such storms at Rome, against 129 at Montecavo. This seems to show that the excess of hail at the mountain station is not attributable to a greater intensity of atmospheric electricity. The author gives a table showing that the monthly mean temperature at Rome is at times about 10° higher than at Montecavo, and suggests that the fusion of the hail in traversing a warmer stratum of air may to some extent account for the smaller amount at the lower station.

PROF. TINE TAMMES describes in the *Zeitschrift für wissenschaftliche Mikroskopie*, xviii. p. 280, a convenient form of electrical lamp for use with the microscope, which has been introduced into the Botanical Laboratory at Groningen. The lamp itself is an incandescent lamp of about 4 cm. diameter, and is enclosed in an iron box the weight of which adds to its steadiness. This box is open at the front and back, the back opening letting out the heat while the front opening is furnished with grooves for inserting glass plates. The front plate is of ground glass, specially chosen for its low absorbing power and absence of coarse grain, and this gives a uniformly bright area as source of illumination. Behind this is a screen of cobalt or other coloured glass for absorbing the superfluous yellow rays.

A PAPER on the metallography or photomicrography of iron and steel is communicated to the *Journal* of the Royal Microscopical Society for February by Mr. William H. Merrett.

The subject is one of recent development, and among other workers the names of Dr. Sorby, Profs. Marten and Wedding, and M. Osmond, of Paris, are mentioned. The paper deals with the analogy between the transformations occurring in steel and in frozen saline solutions, taking as illustrations Sir W. C. Roberts-Austen's diagrams of equilibrium curves. The methods of preparing and polishing steel for opaque examination are described, including Prof. Le Chatelier's method of obtaining sufficiently fine polishing powders. The paper is illustrated by several photographs of the different constituents of iron and steel under a magnification of 850 diameters. Although metallography was originally of scientific interest only, it has now become of the greatest commercial importance.

A VERY remarkable barograph trace obtained during a typhoon on August 2-3, 1901, is given in the *Quarterly Journal* of the Royal Meteorological Society (January), and is here reproduced



Barograph trace during typhoon, August 2–3, 1901.

with the permission of the Society. The barograph was on the steamer *Laisang*, which encountered the typhoon somewhere to the northward of the Formosa Channel, in about lat. 25° N., long. 122° E. or thereabouts. The fall and rise of the barometer were most rapid, the range being no less than two inches in eight hours. The chart shows the minimum reading to have been as low as 27·35 in. at 9 p.m. on August 2. Such a low barometer reading is said in the note from which these particulars are derived to have been rarely recorded. It was, however, exceeded on the following occasions:—27·33 in., February 5, 1870, on board H.M.S. *Tarifa*, 500 miles west of Ireland. 27·332 in., January 26, 1884, Ochtertyre, near Crieff, Scotland (*Quarterly Journal* Royal Meteorological Society, vol. x. p. 114). 27·135 in., September 22, 1885, False Point, Orissa, India (NATURE, vol. xxxv. p. 344). 27·38 in., December 8, 1886, Belfast; probably about 27·28 in. over the north of Ireland (*Quarterly Journal* Royal Meteorological Society, vol. xiii. p. 211).

IN the *Irish Naturalist* for March, Dr. R. F. Scharff records the stranding in Dublin Bay of a specimen of the white-beaked dolphin (*Lagenorhynchus albirostris*). The specimen, which is a male, seems of unusually large size, measuring 12 feet in length, the species being stated in text-books not to exceed 9 feet.

STUDENTS of "distribution" will be interested in a paper by Dr. D. Sharp on Oriental beetles which appears in the March number of the *Entomologists' Monthly Magazine*. The author states that in the group Limnichini—the members of which are remarkable for their death-feigning instinct—he finds a remarkable similarity between the Central American and Oriental forms, amounting in one instance to generic identity.

WE have received the second number of the *Nature-Study Journal*, published by the South-Eastern Agricultural College, Wye, Kent. It contains a description of a country walk through a fossiliferous district in autumn, in which attention is directed to the objects of natural history met with, and also samples of "nature-lessons" for children. The editor asks for outlines of a series of lessons suitable for the same purpose.

IN their eleventh annual report, the Society for the Protection of Birds record an increase in the number of their associates, although they have to deplore a falling-off in subscriptions. With the aid of the Royal Society for the Prevention of Cruelty to Animals, the Society has succeeded in obtaining several convictions during the past year, one of the most satisfactory being in the case of a gamekeeper charged with shooting two of the bustards introduced by Lord Walsingham into Norfolk. Some—although not a great—effect appears to have been made upon the plume-trade by the efforts of the Society; but the recent fashion for the skins of entire terns and the wings of gulls as decorations for ladies' hats is a cause for much regret. So great is the demand for these objects that in Yorkshire alone a single dealer is stated to have contracted to supply 10,000 skins to a London firm. The subject of the Society's second essay competition was "the best means of introducing Bird and Arbor Day into England"; and now that the prizes have been awarded, the Society is hopeful that Coronation year may mark the institution of such a day in all the schools of the country.

THE accompanying diffraction effect is reproduced from a plate contributed by Prof. W. S. Franklin to the January number of the *Physical Review*, and represents one of a number of photographs of shadows cast upon a photo-

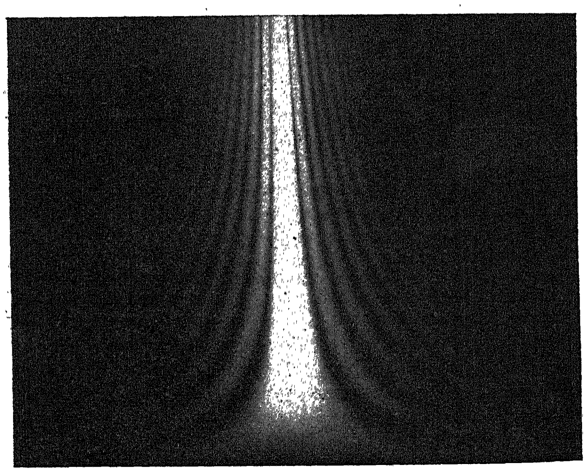


FIG. 1.—Diffraction Shadows of a Tapering Slit.

graphic plate from a monochromatic point of light distant about sixteen metres from the plate. The objects casting the shadows were about three metres from the plate, which was in each case at right angles to the incident light. The

photograph here reproduced shows the shadow of a slit between very carefully worked edges of brass. The slit was about fifteen centimetres in length, tapering from a width of 0·05 centimetre at one end to nearly zero at the other.

IN a recent issue of the *Actes* of the Scientific Society of Chili (vol. xi. part 3), Señor F. Albert publishes an account of the different species of seals frequenting the coasts of that country, together with a summary of the legislation for their protection. It is satisfactory to learn that the Government are fully alive to the necessity for such protection and are doing all they can to see that the various enactments are duly carried out. The regulations forbid any but Chilian subjects to shoot seals or otters at all, while they establish a close time lasting from the beginning of November till the end of February.

TO shake about 200,000 peach trees and 50,000 plum trees for the purpose of dislodging injurious insects is a formidable task, yet it was successfully accomplished several times between April 18 and June 1, 1901, by the Hale Georgia Orchard Company at Fort Valley, Georgia, U.S.A. The insect against which this action was taken was the curculio beetle. The San Jose scale, so prevalent in south Georgia, is thoroughly controlled by the kerosene-water treatment, the beach-tree borer is held in abeyance by the cutting-out method, and the brown rot is fairly well controlled by the Bordeaux treatment, but the curculio baffles all contrivances for its destruction except the

Gang at work catching beetles shaken off fruit trees in Georgia.

tedious method of shaking the trees on which they occur and catching the beetles as they fall. The accompanying illustration from a paper by Messrs. W. M. Scott and W. F. Fiske, in the *Proceedings* of the thirteenth annual meeting of the Association of Economic Entomologists, shows a gang at work catching beetles on sheets stretched upon frames, as they are shaken off the trees. With eleven pairs of sheets, about 40,000 trees were treated in the course of a day. About 137,000 of the beetles were caught and killed during the season, and as a large proportion must have been females capable of depositing eggs, an immense amount of damage was prevented by the work.

TO Mr. O. Voges, of Buenos Ayres, is due the credit of having discovered the smallest bacillus which has yet been identified. It is much smaller than the influenza bacillus, and is only just discernible when magnified about 1500 times. These very minute rods were obtained from abscesses which cattle suffer from in South America, producing a disease known as manquea amongst other names. It is usually found in quite young cattle, and is easily recognisable by the characteristic lameness of one leg which it produces. The bacillus is an anærobe, and produces in artificial cultures the same highly offensive odour which is associated with it in the abscess. Mice, rats and rabbits are quite immune to its action, but guinea-pigs succumb in from 24–48 hours, and the bacilli are found in the heart's blood and all internal organs. Inasmuch as the action of such well-known anærobic pathogenic bacteria as those of tetanus and symptomatic anthrax is due to their toxic products, filtrates of liquid cultures of this bacillus were tested for their toxicity, but even guinea-pigs did not react to such injections, and therefore Voges concludes that the pathogenic action is due to the bacilli themselves and not to their products. An interesting fact noted by Voges is that the animals he inoculated only succumbed when the weather was hot; not once in the winter could he successfully infect one animal. This is also true of the disease in its ordinary course, as the hotter the climate the more fatal are the results. If the abscess is opened in its early stages the disease is arrested and the animal recovers. This simple remedy is recommended by Voges.

THE fourth and concluding number of the second volume of the *West Indian Bulletin* contains several interesting articles. One on the Jamaica fruit trade is a reprint of an account given by a special correspondent in the *Times*, and deals mainly with the successful inauguration of the shipping of bananas to England last year. Mr. A. R. Gilzean contributes a sketch of the history of rice-growing in British Guiana. As a very large proportion of the population of the country is composed of East Indian coolies well acquainted with rice cultivation, there can be no doubt that in time rice will become an important article of commerce, the local conditions being described as ideal. An account is given of recent experiments with sweet potatoes, the cultivation of different varieties in various islands, methods of storage, preparation of meal, &c. Sweet potatoes form a staple food in the islands, and the Imperial Department of Agriculture is endeavouring to induce English people to cultivate a taste for the vegetable by sending fortnightly supplies to London, printed information being given to purchasers as to fifteen different ways of preparing for table. Mr. Maxwell-Lefroy has a lengthy article on suggestions for insect control in the West Indies. He proposes five principal ways of attacking the problems—measures to prevent the introduction of new diseases (such as quarantine or the regulation of plant importation); the adoption of preventive measures; also of remedial measures; the encouragement of useful native birds and other organisms; and the introduction of new insectivorous birds, insects, &c., and the regulation of the importation of new animals. Other papers relate to bee-keeping, "thrips" and "witch-broom" diseases on cacao, methods for destroying land crabs, treatment of imported plants at Jamaica, citrate of lime and concentrated lime juice, &c. The number includes the index to the volume.

THERE are several indications in various islands of the Indo-Pacific region that the fact of being tattooed is thought to be beneficial when the soul passes into the next world. The last example of this belief is an account in *Globus* (Bd. lxxxi. p. 46), by Prof. G. Thilenius, of the tattooing of women in the Laughlan Islands, or Nada, a small group of islands east of the southern end of New Guinea. A considerable surface of the women is tattooed with angled designs, but concentric circles are tattooed on the legs. The belief is that between the Laughlan Islands and the island of Vatum in the Trobriand group, to which their souls should go, there is a great snake over which they must pass. The snake asks each soul for her tattooing. The soul takes off her tattooing and gives it to the snake, who covers itself with it. The snake then becomes broad and flat and the soul passes over, as on a bridge. If the soul is not tattooed the snake shrinks, becomes very narrow, and the soul falls into the sea and cannot reach Vatum. These wretched souls become fish.

PROF. A. TARENETSKY, in an elaborate work, "Beiträge zur Skelet und Schaedelkunde der Aleuten, Konaegen, Kenai

und Koljuschen, mit vergleichend anthropologischen Bemerkungen," published by the Russian Academy of Sciences, has come to very interesting conclusions concerning the still problematic origin of these hyperboreans. His researches are based upon thirty-five skulls and two complete Aleutian skeletons of the museum of the Academy, skulls of other East Asian natives, borrowed from the Medical Academy Museum, having been used for comparison. The conclusions of the author are as follows:—The Aleute skulls represent a strongly pronounced type and offer few traces of mixture with other tribes; notwithstanding some secondary differences, the skulls of both the western and the eastern Aleutes are similar to each other. As to the Konyag skulls, although they mostly are artificially deformed, they are nevertheless very similar to those of the American Indians on the one side and to those of the Aleutes on the other side. They also sharply differ from the skulls of both the western and the eastern Eskimos. Between the Kenais and the Koloshes there is no difference as regards their skulls, which are very near to the skulls of the Aleutes and the Konyags, representing the same type, which is only slightly altered with the Konyags by artificial deformation and by admixture of foreign blood. Consequently, the author makes the supposition that all the four stems have a common origin and are descendants of an Indian stem which belonged, not to the Eskimos, but to the American Red Indians. As to the skeletons of the Aleutes, they are very typical, especially on account of the structure of the very long extremities, and these peculiarities are not known in skeletons of other tribes. Only a few bones, unearthed a couple of years ago in Mongolia and belonging to some probably Turkish stem, offered some likeness with the Aleute skeletons. This find induces the author to believe that the populations of north-west America and Asia may have had a common origin, as they communicated across the Bering Strait. Only part of the Aleute and Konyag skulls had been described by Baer, the remainder being now described for the first time.

DR. T. K. ROSE's treatise on "The Metallurgy of Gold," the fourth edition of which has just been published by Messrs. C. Griffin and Co., provides students of metallurgy and managers of gold mines and smelting works with a concise and valuable statement of the existing conditions of the industry in which they are interested. As an Associate of the Royal School of Mines, Dr. Rose has been able to obtain particulars of practical developments of the metallurgy of gold in many parts of the world. His book has been revised and extended in order to keep it in touch with recent progress, and the changes will enable it to retain its position as a standard work on the subject with which it deals.

THE Hampstead Scientific Society appears to be in a flourishing condition, judging from the Report for 1901, just received. Among the subjects of lectures delivered before the Society during the session covered by the report are curious fish, lodestone lore, a glimpse at the work of Lord Kelvin, the amœba and its allies, the form of the earth, and the human eye. There is an astronomical section; and, as the Society possesses a telescope, observations can be made of celestial objects discussed at the class meetings. The natural history section has in preparation an account of the fauna and flora of Hampstead and its neighbourhood, which it is hoped will be sufficiently advanced for the first part to appear in the autumn of this year. The report points out that a natural history museum would greatly add to the scientific welfare of Hampstead; so that support should be given to the Hampstead Borough Council's scheme for a public museum and art gallery.

SOME time since, MM. Sabatier and Senderens discovered that metallic nickel, reduced from its oxide at as low a temperature as possible, possessed extraordinary catalytic power with regard to the addition of hydrogen, and from time to time they have published numerous syntheses carried out in this way. In the current number of the *Comptes rendus* is given an extremely elegant synthesis of methane based upon the same reaction. It was found that if either carbon monoxide or dioxide mixed with a slight excess of hydrogen is passed over reduced nickel at temperatures between 250° and 300° C., the oxide is reduced and methane is quantitatively produced. In spite of the fundamental importance of the synthesis of methane in organic chemistry, none of the syntheses realised up to the present are of sufficient simplicity and directness to be realised on the lecture table. The new method allows of the preparation of methane from its elements in two steps only, and will doubtless take its place as a standard lecture experiment.

THE additions to the Zoological Society's Gardens during the past week include two Martinican Doves (*Zenaida aurita*), a White-winged Zenaida Dove (*Melopelia leucoptera*) from the West Indies, presented by Mr. D. Seth Smith; a Black-backed Piping Crow (*Gymnorhina tibicen*) from Australia, presented by Mrs. J. Rose; three Derbian Zonures (*Zonurus giganteus*) from South Africa, presented by Captain H. M. Tristram, 12th Lancers; a Slow Loris (*Nycticebus tardigradus*) from Borneo, four Derbian Zonures (*Zonurus giganteus*) from South Africa, six Dark-green Snakes (*Zamenis gemonensis*) European, deposited; a Panda (*Ælurus fulgens*) from Nepal, a Green Bittern (*Butorides virescens*) from America, purchased.

OUR ASTRONOMICAL COLUMN.

NEW ANNUAL TERM IN THE VARIATION OF LATITUDE.—In the *Astronomical Journal*, vol. xxii. pp. 107-108, Prof. H. Kimura announces that from a detailed examination of the observations taken for variation of latitude he has detected a periodicity in the residuals obtained, which appears to indicate the existence of a hitherto unrecognised annual component. Most of the observations were collected in Prof. Albrecht's report in the *Astronomische Nachrichten*, No. 3734. The maximum amplitude of the new term is about 0″·03. At present it is impossible to examine the dependence of this element on geographical position, as the materials have been combined from all stations between $\phi=60°$ N. and $\phi=21°$ N., and the term as found would correspond to a mean latitude 42° N. A future series of observations in different parallels will possibly settle if the new component is a function of the latitude. From the variation curve it appears that the new term has zero values at 0·33 and 0·85, maximum at 0·0 and minimum at 0·57; a noticeable feature of this is that the zeroes lie near the equinoxes, the maxima and minima near the solstices.

OBSERVATIONS OF JUPITER.

JUPITER is now conspicuously visible as a morning star. During the ensuing spring and summer, observers of this planet will have some interesting features to reexamine, though his position, about 19 degrees south of the equator, cannot be regarded as favouring telescopic study. At the time of opposition on August 5 next he will, however, be placed 5 degrees further north than last year, and this will make a sufficient difference in his altitude to improve markedly the general definition of the markings. During the seven months from May to November, 1901, the writer, with a 10-inch reflecting telescope, secured observations of Jupiter on 76 nights, but the image was usually very indistinct and unsteady, and it was only on two or three occasions that the disc was sufficiently sharp to present the more delicate features satisfactorily.

This planet is always interesting from the large number and frequently conspicuous character of the details shown on his surface. These details consist of spots or patches of various tints, forms and sizes situated either on the dusky belts or on the alternating bright zones. The proper motions which affect these markings and displace their relative positions from day to day furnish a mass of material for prolonged study, while the oft-recurring and sometimes rapid changes taking place in their visible aspect provide an attractive field for the draughtsman.

During the present year, observational research in reference to this object is likely to prove of an unusually interesting character, as there are several features which deserve (and will doubtless receive) special attention. During 1901, the red spot exhibited a singular acceleration of motion when compared with its rate in previous years, for it maintained a longitude of 45°, consistently with a rotation period of 9h. 55m. 40s.·6, upon which system II. of Mr. Crommelin's ephemerides is based. It will therefore be most important to trace the position of the spot in ensuing months, as it seems probable that this curiously durable marking, after a constantly increasing retardation between about 1878 and 1900 which augmented its rotation period from 9h. 55m. 34s.·5 to 9h. 55m. 41s.·8, will now travel with greater celerity and give a period becoming shorter with the time until the minimum is reached. If these oscillations in velocity are developed at regular intervals, it will soon be possible to determine the length of the cycle for observations of the red spot or of the hollow in the great southern belt date from 1831. There is some significant evidence in support of the conjecture that the motion of certain markings as well as the apparition of particular spots in various latitudes are recurrent on the planet, and some of the reappearances appear to take place at periods not differing materially from the time of Jupiter's revolution round the sun. The red spot may be looked for near mid-transit on March 13 at 18h. 7m., on March 25 at 18h. 4m., on March 30 at 17h. 13m., on April 6 at 18h. 0m., and on April 11 at 17h. 9m.

Observers should now endeavour to redetect the rapidly moving dark spots which appeared in the north temperate belt of Jupiter in 1880 and 1891. There were a number of spots visible in this latitude in 1901, but the writer found their mean rate of rotation 9h. 55m. 50s. This is nearly 8 minutes in excess of the rotation period found for certain irregular markings in approximately the same latitude in the autumn of 1880 which gave a rate of 9h. 48m. It is a very singular circumstance that in a similar latitude of Jupiter spots are developed showing respectively the shortest and longest rotation periods of any which have ever been observed.

In 1901, a large dark spot was often seen in the south or tropical[1] zone of the planet, and this may prove a repetition of the object observed in the same latitude in 1889–91. This spot exhibits a rotation period of 9h. 55m. 18s.·5, and its more rapid movement will enable it to overtake the red spot in about June, 1902, should both the markings remain visible until that month. The longitude of the south temperate or tropical spot will be as follows during the next three months, and it will follow the red spot at the time-intervals stated if the latter object retains the same longitude (=45°) as in 1901 :—

1902	Longitude	Follows Red spot. h.	m.
March 17	110·5	1	48
April 17	94·1	1	21
May 17	77·7	0	54

The writer obtained an observation of this marking on February 27, when it appeared to be central at 18h. 40m., which would make its longitude 123°·8, but it was very imperfectly seen. The instrument used was a 4-inch Cooke refractor, power 175.

Another important feature for reobservation in 1902 will be the white and dark spots plentifully grouped along the equatorial region of the planet. In the three years 1898, 1899 and 1900, the rotation period of the equatorial current differed very little, the mean value from a large number of spots being 9h. 50m. 24s., or 5m. 17s.·7 less than the rate of the red spot. But in 1901 the mean rotation period of 28 equatorial spots observed at Bristol was 9h. 50m. 29s., or 5m. 12s. less than that of the red spot.

When further observations of these variations have been pursued during many oppositions, the outcome may be both interesting and important as affording a good clue to the physical condition and phenomena of the planet. That great atmospheric changes are in progress on the disc is evident, and it is the facility with which they may be observed and compared which renders this object a singularly attractive one to the possessors of telescopes.

W. F. DENNING.

[1] This interesting marking exhibited a motion coinciding with that of objects placed in the planet's south temperate zone, though its position encroached on the south tropical as well as the south temperate region.

MAGIC SQUARES AND OTHER PROBLEMS UPON A CHESS-BOARD.[1]

THE construction of magic squares is an amusement of great antiquity; we hear of them being constructed in India and in China before the Christian era, whilst they appear to have been introduced into Europe by Moschopulus, who flourished at Constantinople early in the fifteenth century. On the diagram you see a simple example of a magic square, one celebrated as being drawn by Albert Dürer in his picture of "Melancholy," painted about the year 1500 (Fig. 1). It is one of the fourth order, involving 16 compartments or cells. In describing such squares, the horizontal lines of cells are called "rows," the vertical lines "columns," and the oblique lines going from corner to corner

1	15	14	4
12	6	7	9
8	10	11	5
13	3	2	16

FIG. 1.

"diagonals." In the 16 compartments are placed the first 16 numbers, 1, 2, 3, . . . 16, and the magic property consists in this, that the numbers are placed in such wise that the sum of the numbers in every row, column and diagonal is the same, viz., in this case, 34.

It is probable that magic squares were so called because the properties they possessed seemed to be extraordinary and wonderful; they were, indeed, regarded with superstitious reverence and employed as talismans. Cornelius Agrippa constructed magic squares of orders 3, 4, 5, 6, 7, 8, 9, and associated them with the seven heavenly bodies, Saturn, Jupiter, Mars, the Sun, Venus, Mercury and the Moon. A magic square engraved on a silver plate was regarded as a charm against the plague, and to this day such charms are worn in the east.

However, what was at first merely a practice of magicians and talisman makers has now for a long time become a serious

study for mathematicians. Not that they have imagined that it would lead them to anything of solid advantage, but because the theory of such squares was seen to be fraught with difficulty, and it was considered possible that some new properties of numbers might be discovered which mathematicians could turn to account. This has, in fact, proved to be the case; for from a certain point of view the subject has been found to be algebraical rather than arithmetical, and to be intimately connected with great departments of science, such as the "infinitesimal calculus," "the calculus of operations" and the "theory of groups."

In the next diagram (Fig. 2) I show you a magic square of order 5, the sum of the numbers in each row, column and

[1] A discourse delivered at the Royal Institution on Friday evening, February 14, by Major P. A. MacMahon, F.R.S.

diagonal being 65. This number 65 is obtained by multiplying 25, the number of cells, by the next higher number, 26, and then dividing by twice the order of the square, viz., 10. A similar rule applies in the case of a magic square of any order. The formation of these squares has a fascination for many persons, and, as a consequence, a large amount of ingenuity has been expended in forming particular examples and in discovering general principles of formation. As an example of the amount of labour that some have expended on this matter, it may be mentioned that in 1693 Frénicle, a Frenchman, published a work of more than 500 pages upon magic squares. In this work he showed that 880 magic squares of the fourth order could be constructed, and in an appendix he gave the actual diagrams of the whole of them. The number of magic squares of the order 5 has not been exactly determined, but it has been shown that the number certainly exceeds 60,000.

As a consequence it is not very difficult to compose particular specimens, and, for the most part, the fascinated individuals, to whom I have alluded, have devoted their energies to the discovery of principles of formation. Of such principles I will give a few, remarking that the cases of squares of uneven order 1, 3, 5 . . . are more simple than those of even order 4, 6, . . . and that no magic square of order 2 exists at all. The simplest of all methods for an uneven order is shown in the diagram (Fig. 3), where certain additional cells are added to the square, the numbers written as shown in natural order diagonally, and then the numbers which are outside the square

FIG. 3.

projected into the empty compartments according to an easily understood law. The second method is associated with the name of De la Loubère, though it is stated that he learnt it during a visit to Siam in 1687. The number 1 (see Fig. 2) is placed in the middle cell of the top row, and the successive numbers placed in their natural order in a diagonal line sloping upwards to the right subject to the laws:—

(1) When the top row is reached, the next number is written at the bottom of the next column.

(2) When the right-hand column is reached, the next number is written on the left of the row above.

(3) When it is impossible to proceed according to the above rules, the number is placed in the cell immediately below the last number written.

If we commence by writing the number 1 in any cell except that above indicated, a square is reached which is magic in regard to rows and columns, but not in regard to diagonals.

Subsequent writers have shown that starting with the left-hand bottom cell and using the move of the knight instead of that of the bishop, the general principle of De la Loubère will also lead to a magic square (Fig. 4). The next method is that of De la Hire, and dates from 1705. Two subsidiary squares are constructed as shown, the one involving five numbers 1, 2, 3, 4, 5, and the other five numbers 0, 5, 10, 15, 20. When these squares are properly formed and a third square constructed by adding together the numbers in corresponding cells, this third square is magic (Fig. 5). Time does not permit me to enter into the exact method of forming the subsidiary squares, and I will merely mention that each of them possesses a particular property, viz., only five different numbers are involved, and all five appear in each column and in each row; in other words, no row and no column contains two numbers of the same kind, but no diagonal property is necessarily involved. Such squares are of a great scientific importance, and have been termed by Euler and subsequent writers "Latin squares," for a reason that will presently appear. From a scientific point of view, the chief interest of all arrangements such as I consider this evening lies, not in their actual formation, but in the enumeration of all possible ways of forming them, and in this respect very little has been hitherto

achieved by mathematicians. No person living knows in how many ways it is possible to form a magic square of any order exceeding 4. The fact is, that before we can attempt to enumerate magic squares we must see our way to solve problems of a far more simple character. For example, before we can enumerate the squares that can be formed by De la Hire's method we must take a first step by finding out how many Latin squares can be formed of the different orders. For the order 5 the question is, "In how many ways can five different objects be placed in the cells so that each column and each

row contains each object?" It may occur to some here this evening that such a discussion might be interesting or curious, but could not possibly be of any scientific value. But such is not the case. A department of mathematics that is universally acknowledged to be of fundamental importance is the "theory of groups." Operations of this theory and those connected with logical and other algebras possess what is termed a "multiplication table," which denotes the laws to which the operations are subject. In Fig. 6 you see such a table of order 6 slightly modified from Burnside's "Treatise on the Theory of Groups"; it is, as you see, a Latin square, and the chief problem that awaits solution is the enumeration of such tables; the

questions are not parallel because *all* Latin squares do not give rise to tables in the theory of groups; but still, we must walk before we can run, and a step in the right direction is the enumeration of *all* Latin squares. When I call to mind that the theory of groups has an important bearing upon many branches of physical science, notably upon dynamics, I consider that I have made good my point.

I now concentrate attention on these Latin squares, and observe that the theory of the enumeration has nothing to do with the particular numbers that occupy the compartments; the only essential is that the numbers shall be different one from another. My attention was first called to the subject of the Latin square by a work of the renowned mathematician Euler, written in 1782, entitled "Recherches sur une nouvelle espèce de Quarrés Magiques." I may say that Euler seems to have been the first to grasp the necessity of considering squares possessing what may be termed a magical property of a far less recondite character than that possessed by the magic squares of the ancients, and, as we shall see presently, he might have gone a

step further in the same direction with advantage and have commenced with arrangements of a more simple character than that of the Latin square, with arrangements, in fact, which present no difficulties of enumeration, but which supply the key to the unlocking of the secrets of which we are in search. He commences by remarking that a curious problem had been exercising the wits of many persons. He describes it as follows:—There

$a\alpha$	$a\beta$	$a\gamma$	$a\delta$	$a\epsilon$	$a\theta$
$b\alpha$	$b\beta$	$b\gamma$	$b\delta$	$b\epsilon$	$b\theta$
$c\alpha$	$c\beta$	$c\gamma$	$c\delta$	$c\epsilon$	$c\theta$
$d\alpha$	$d\beta$	$d\gamma$	$d\delta$	$d\epsilon$	$d\theta$
$e\alpha$	$e\beta$	$e\gamma$	$e\delta$	$e\epsilon$	$e\theta$
$f\alpha$	$f\beta$	$f\gamma$	$f\delta$	$f\epsilon$	$f\theta$

FIG. 7.

are 36 officers of six different ranks drawn from six different regiments, and the problem is to arrange them in a square of order 6, one officer in each compartment, in such wise that in each row, as well as in each column, there appears an officer of each rank and also an officer of each regiment. Of a single regiment we have, suppose, a colonel, lieutenant-colonel, major, captain, first lieutenant and second lieutenant, and similarly for five other regiments, so that there are in all 36 officers who must be so placed that in each row and in each column each rank is represented, and also each regiment. Euler denotes the six regiments by the Latin letters a, b, c, d, e, f, and the six ranks by the Greek letters $\alpha, \beta, \gamma, \delta, \epsilon, \theta$, and observes that the character of an officer is determined by a combination of two letters, the one Latin and the other Greek; there are 36 such combinations, and the problem consists in placing these combinations in the 36 compartments in such wise that every row and every column contains the 6 Latin letters and also the 6 Greek letters (Fig. 7). Euler found no solution of this problem in the case of a square of order 6, and since Euler's time no one has succeeded either in finding a solution or in proving that no solution exists. Anyone interested has, therefore, this question before him at the present moment, and I recommend it to any-

$a\alpha$	$b\gamma$	$c\beta$
$b\beta$	$c\alpha$	$a\gamma$
$c\gamma$	$a\beta$	$b\alpha$

FIG. 8.

one present who desires an exercise of his wits and a trial of his patience and ingenuity. It is easy to prove that when the square is of order 2, viz. the case of 4 officers of two different ranks drawn from two different regiments, there is no solution; Euler gave his opinion to the effect that no solution is possible whenever the order of the square is two greater than a multiple of four. In other simple cases he obtained solutions; for example, for the order 3, the problem of 9 officers of three different ranks drawn from three different regiments, it is easy to discover the solution shown in the diagram (Fig. 8), and, as demonstrated by Euler, whenever one solution has been constructed there is a simple process by which a certain number of others can be derived from it. Now if you look at that diagram and suppose the Greek letters obliterated, you will see that the Latin letters are arranged so that each of the letters occurs in each row and in each column, the magical property mentioned above, and for this reason Euler termed such arrangements Latin squares and stated that the first step in the solution of the problem is to enumerate the Latin squares of a given order. As showing the intimate connection between the Græco-Latin square of Euler and ordinary magic squares, it should be noticed that the method of De la Hire, by employing Latin and Greek letters for the elements in his two subsidiary Latin squares, gives rise immediately to the Græco-Latin square of Euler. Euler says in regard to the problem of the Latin square, "The complete enumeration of the Latin squares of a given order is a very important question, but seems to me of extreme difficulty, the more so as all known methods of the doctrine of combinations appear to give us no help," and again, "the enumeration appears to be beyond the bounds of possibility when the order exceeds 5." Moreover, Cayley, in 1890, that is 108 years later, gave a *résumé* of what had been done in the matter, but did not see his way to a solution of the question. Under these circumstances, you will see how futile it is to expect a solution of the magic-square problem when the far simpler question of the Latin square has for so long proved such a tough nut to crack. The problem of the Latin square has eventually been completely solved, and in order to lead you up gradually to an understanding of the method that has proved successful, I ask you to look at the Latin square of order 5 that you see in the diagram (Fig. 9). The first row of letters can be written in any order, but not so the second row, for each column when the second row is written must contain two different

a	b	c	d	e
b	d	e	a	c
c	e	d	b	a
d	c	a	e	b
e	a	b	c	d

FIG. 9.

letters. We must, therefore, be able to solve the comparatively simple question of the number of possible arrangements of the first two rows. For a given order of the letters in the first row, in how many ways can we write the

letters in the second row so that each column contains a pair of different letters? This is a famous question, of which the solution is well known; it is known to mathematicians as the "problème des rencontres." It may be stated in a variety of ways; one of the most interesting is as follows:—A person writes a number of letters and addresses the corresponding envelopes; if he now put the letters at random into the envelopes, what is the probability that not a single letter is in the right envelope?

Passing on to the problem of determining the number of ways of arranging the first three rows so that each column contains three different letters, it may be stated that up to 1898 no solution of it had been given; while it is obvious that as the number of the rows is increased the resulting problems will be of enhanced difficulty. A particular case of the three-row problem had, however, been considered under the title "problème des ménages" and a solution obtained. It may be stated as follows:—

A given number of married ladies take their seats at a round table in given positions; in how many ways can their husbands be seated so that each is between two ladies, but not next to his own wife? For order 5, that is 5 ladies, the question comes to this:—Write down 5 letters and underneath them the same letters shifted one place to the left; in how many ways can the third row be written so that each column contains three different letters? This particular case of the three-row problem for any order presents no real difficulty. The results are that in the cases of 3, 4, 5, 6 . . . married couples there are 1, 2, 13, 80, &c., ways.

Since the year 1890, the problem of the Latin square has been completely solved by an entirely new method, which has also proved successful in solving similar questions of a far more recondite character, and I am here this evening to attempt to give you some notion of the method and some account of the series of problems to which that method has been found to be applicable.

There is, as viewed mathematically, a fundamental difference between arithmetic and algebra; the former may be regarded as an algebra in which the numerical magnitudes under consideration are restricted to be integers; the two branches contemplate discontinuous and continuous magnitude respectively. Similarly, in geometry we have the continuous theory, which contemplates figures generated by points moving from one place to another and in doing so passing over an infinite succession of points, tracing a line in a plane or in space, and also a discontinuous theory, in which the position of a point varies suddenly, *per saltum*, and we are not concerned with any continuously varying motion or position. The present problems are concerned sometimes with this discontinuous geometry and sometimes with an additional discontinuity in regard to numerical magnitude, and the object is to count and not to measure. Far removed as these questions are, apparently, from the subject-matter of a calculus of infinitely small quantities and the variation of quantities by infinitesimal increments, my purpose is to show that they are intimately connected with them and that success is a necessary consequence of the relationship. I must first take you to a much simpler problem than that of the Latin square, to one which in a variety of ways is very easy of solution, but which happens to be perhaps the simplest illustration of the method. In the game of chess a castle can move either horizontally or vertically, and it is easy to place 8 castles on the board so that no piece can be taken by any other piece. One such arrangement is shown in Fig. 10. The condition is simply that one castle must be in each row and also in each column. Every such arrangement is a diagrammatic representation of a certain mathematical process performed upon a certain algebraical function. For consider the process of differentiating x^8; it may be performed as follows:—Write down x^8 as the product of 8 x's,

$$x\ x\ x\ x\ x\ x\ x\ x,$$

and now substitute unity for x in all possible ways and add the results; the substitution can take place in eight different ways, and the addition results in $8x^7$, which will be recognised as the differential coefficient. Observe that the process of differentiation is thus broken up into eight minor processes, each of which may be diagrammatically represented on the first row of the chess-board by a unit placed in the compartment corresponding to the particular x for which unity has been substituted. If we now perform differentiation a second time, we may take the results of the above minor processes and in each of them again substitute unity for x in all possible ways; since in each the substitution can take place in seven different ways, it is seen that we can regard the process of differentiating twice as composed of $8 \times 7 = 56$ minor processes, each of which can be diagrammatically represented by two units, one in each of the first two rows of the chess-board, in positions corresponding to the substitutions of unity for x that have been carried out. Proceeding in this manner in regular order up to the eighth differentiation, we find that the whole process of differentiating x^8 eight times in succession can be decomposed into $8 \times 7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1 = 40{,}320$ minor processes, each of which is denoted by a diagram which slight reflection shows is a solution of the castle problem (Fig. 11). There are, in fact, no more solutions, and the whole series of 40,320 diagrams

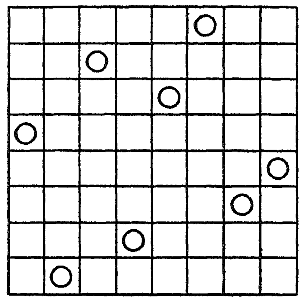

FIG. 10.

constitutes a picture in detail of the differentiations. Simple differentiations of integral powers thus yield the enumerative solutions of the castle problem on chess-boards of any size.

We have here a clue to a method for the investigation of these chess-board problems; it is the grain of mustard seed which has grown up into a tree of vigorous growth, throwing out branches and roots in all sorts of unexpected directions. The above illustrations of differentiation gave birth to the idea that it might be possible to design pairs of mathematical processes and functions which would yield the solution of chess-board problems of a more difficult character. Two plans of operation present themselves. In the first place we may take up a particular question, the Latin square for instance, and attempt to design, on the one hand, a process, and, on the

FIG. 11.

other hand, a function the combination of which will lead to the series of diagrams. In the second place, we may have no particular problem in view, but simply start by designing a process and a function, and examine the properties of the series of diagrams to which the combination leads. The first of these plans is the more difficult, but was actually accomplished in the case of the Latin square and some other questions; but the second plan, which is the proper method of investigation, met with great success, and the Latin square was one of its first victims, a solution of a more elegant nature being obtained than that which had resulted from the first plan of operations. There is such an extensive choice of processes and functions that many solutions are obtainable of any particular problem. I will now

give you an idea of a solution of the Latin square, which is not the most elegant that has been found, but which is the most suitable to explain to an audience. Suppose we have five collections of objects, each collection containing the same five different objects, *a*, *b*, *c*, *d*, *e* (Fig. 12). I suppose the objects distributed amongst five different persons in the following manner:—The first person takes one object from each collection, so as to obtain each of the five objects; he can do this in 120 different ways; we will suppose that he takes *a* from the first, *b* from the second, *c* from the third, *d* from the fourth, *e* from the fifth; the collections then become as you see in Fig. 12, second row. Now suppose the second man to advance with the intention of taking one object from each collection and obtaining each of the five objects, he has not the same liberty of choice as had the first, because he cannot take *a* from the first collection or *b* from the second, &c. However, he has a good choice in his selection, and we will suppose him to take *b* from the first collection, *d* from the second, *e* from the third,

$$\begin{array}{ccccc}
(abcde) & (abcde) & (abcde) & (abcde) & (abcde) \\
(.bcde) & (a.cde) & (ab.de) & (abc.e) & (abcd.) \\
(..cde) & (a.c.e) & (ab.d.) & (.bc.e) & (ab.d.) \\
(...de) & (a.c..) & (ab...) & (..c.e) & (.b.d.) \\
(....e) & (a....) & (.b...) & (..c..) & (...d.)
\end{array}$$

FIG. 12.

a from the fourth, *c* from the fifth. The collections then become as you see in the third row. The third man who has the same task finds his choice more restricted, but he elects to take *c* from the first, *e* from the second, *d* from the third, *b* from the fourth and *a* from the fifth. The fourth man finds he can take *d*, *c*, *a*, *e*, *b*, and this leaves *e*, *a*, *b*, *c*, *d* for the last man. If we plot the selections that have been made by the five men, we find the Latin square shown in Fig. 9.

Every division of the objects that can be made on this plan gives rise to a Latin square, and all possible distributions give rise to the whole of the Latin squares. Now it happens that a mathematical process exists (connected with algebraical symmetric functions) that acts towards a function representing the five collections in exactly the same way as I have supposed the men to act, and when the process is performed five times in succession, an integer results which denotes exactly the number of Latin squares of order 5 that can be constructed. Moreover, *en route* the "problème des rencontres" and the problems connected with any definite number of rows of the space are also solved.

I will now mention some questions of a more difficult character that are readily solved by the method. In the

$$\begin{array}{cccc} a & a & b & c \\ a & b & c & a \\ b & c & a & a \\ c & a & a & b \end{array} \qquad \begin{array}{cccc} a & a & b & b \\ a & b & a & b \\ b & b & a & a \\ b & a & b & a \end{array} \qquad \begin{array}{cccc} a & a & a & b \\ a & a & b & a \\ a & b & a & a \\ b & a & a & a \end{array}$$

FIG. 13.

"problème des ménages" you will recollect that the condition was that no man must sit next to his wife. If the condition be that there must be at least four (or any even number) persons between him and his wife, the question is just as easily solved. Latin squares where the letters are not all different in each row and column are easily counted. Illustrations of these are shown in Fig. 13. One of these extended to order 8 gives the solution of the problem of placing 16 castles on a chess-board, 8 black and 8 white, so that no castle can take another of its own colour.

Theoretically, the Græco-Latin squares of Euler can be counted, but I am bound to say that the most laborious calculations are necessary to arrive at a numerical result or even to establish that in certain cases the number sought is zero.

Next consider a square of any size and any number of different letters, each of which must appear in each row and in each column, while there is no restriction as to the number that may appear in any one compartment. In this case the result is very simple; suppose the square of order 4 (Fig. 14), and that there are seven different letters that must appear in each row and column; the number of arrangements is $(4\,!)^7$, viz., 4, the order of the square, must be multiplied by each lower number and the number thus reached multiplied seven times by itself.

Finally, if there be given for each row and for each column a different assemblage of letters and no restriction be placed upon the contents of any compartment, the number of squares in which all these conditions are satisfied can be counted. This, of course, is a far more recondite question than that of the Latin square, and cannot be attacked at all by any other method.

I now pass to certain purely numerical problems. Suppose we have a square lattice of any size and are told that numbers are to be placed in the compartments in such wise that the sums of the numbers in the different rows and columns are to have any given values the same or different. This very general question, hitherto regarded as unassailable, is solved quite easily. The solution is not more difficult when the lattice is rectangular instead of square and when any desired limitation is imposed upon the magnitude of the numbers.

Up to this point, the solutions obtained depend upon processes of the differential calculus. A whole series of other problems, similar in general character, but in one respect essentially different, arises from the processes of the calculus of finite differences. Into these time does not permit me to enter. In the case of magic squares as generally understood, the method brought forward marks a distinct advance in connection with De la Hire's method of formation by means of a pair of Latin squares, but apart from this a great difficulty is involved in the condition

abcd	·	ef	g
e	abc	dg	f
f	deg	ab	c
g	f	c	abde

FIG. 14.

that no two numbers must be the same. Still, a statement can be made as to a succession of mathematical processes which result in a number which enumerates the magic squares of a given order. In any cases except those of the first few orders, the processes involve an absolutely prohibitive amount of labour, so that it cannot yet be said that a practical solution of the question has been obtained.

Scientifically speaking, it is the assignment of the processes and not the actual performance of them that is interesting; it is the method involved rather than the results flowing from the method that is attractive; it is the connecting link between two, to all appearance, widely separated departments of mathematics that it has been fascinating to forge and to strengthen. Of all the subjects that for hundreds of years past have from time to time engaged the attention of mathematicians, perhaps the most isolated has been the subject of these chess-board arrangements. This isolation does not, I believe, any longer exist. The whole series of diagrams formed according to any given laws must be regarded as a pictorial representation, in greatest detail, of the manner in which a certain process is performed. We have to exercise our wits to discover what this process is. To say and to establish that problems of the general nature of the magic square are intimately connected with the infinitesimal calculus and the calculus of finite differences is to sum the matter up. Much, however, remains to be done. The present method is not able to deal with diagonal properties, or with arrangements which depend upon the knight's move. The subject is only in its infancy at present. More workers

are required who will, without doubt, introduce new ideas and obtain results far transcending those we are in possession of now. The latest work has shown that the method is applicable to boards of triangular and trapezoidal shapes, and also to solid boards in three dimensions, so that the remote ground occupied by magic and Nasik cubes will soon be invaded.

In conclusion, I bring before you an interesting example of magic arrangement that I found whilst engaged in rummaging amongst the books and documents of the old Mathematical Society of Spitalfields (1717–1845) for the purpose of extracting something which might interest or amuse, if it might not instruct, the audience I addressed in Section A of the British Association for the Advancement of Science at Glasgow last autumn. It is an arrangement of the first eighteen numbers on five connected triangles; the magical property consists in the circumstance that the numbers 19, 38 and 57 appear as sums in a variety of ways. The number 19 appears nine times, 38 twelve times and 57 fourteen times (Fig. 15).

\end{aligned}
$$

FIG. 15.

I should say that I feel conscious that I have not been able to introduce the subject of my lecture without occasional and, perhaps, in the circumstances, unavoidable obscurity. For the rest, I have felt somewhat doubtful as to the interest I might arouse in these problems, but the managers honoured me by inviting me to display to you some of the chips from a pure mathematician's workshop, and I felt no hesitation in accepting.

FORTHCOMING BOOKS OF SCIENCE.

Mr. Felix Alcan (Paris) promises:—"Les Bases scientifiques de l'Éducation physique," by Démeny; "Les Grands Phénomènes géologiques," by Prof. S. Meunier; "Manuel d'Electrothérapie," by A. Weill; "Traité d'Intubation du Larynx," by Bonain; "Manuel d'Histologie pathologique," tome ii., by MM. Durante, Dominici, &c.

Mr. Edward Arnold gives notice of:—"Elementary Principles in Statistical Mechanics, by Dr. J. W. Gibbs, and "The Elements of Experimental Phonetics," by Dr. E. W. Scripture.

Messrs. G. Bell and Sons announce:—"Comparative Anatomy of Animals, an Introduction to the Study of," by Dr. G. C. Bourne, vol. ii.:—The Coelomata, illustrated; "Elementary General Science," by D. E. Jones and Dr. D. S. Macnair; "Injurious and Useful Insects," by Prof. L. C. Miall, F.R.S., illustrated; "Physiography," by H. N. Dickson; "Electricity and Magnetism," by Dr. Oliver J. Lodge, F.R.S.; "Light," by A. E. Tutton, F.R.S.

Messrs. A. and C. Black promise:—"Problems in Astrophysics," by Agnes M. Clerke, and a new edition of the same writer's "History of Astronomy during the Nineteenth Century."

The announcements of the Cambridge University Press include:—"Catalogue of Scientific Papers," compiled by the Royal Society, vol. xii., supplementary volume; "Scientific Papers," by John William Strutt, Baron Rayleigh, F.R.S., vol. iv.; "Theory of Differential Equations," by Prof. A. R. Forsyth, F.R.S., part iii.:—Ordinary Linear Equations; "Mathematical Analysis," by E. T. Whittaker; "The Algebra of Invariants," by J. H. Grace and A. Young; "Electric Waves, being an Adams Prize Essay in the University of Cambridge," by H. M. Macdonald, F.R.S.; "A Treatise on Determinants," by R. F. Scott, a new edition by G. B. Mathews, F.R.S.; "The Electrical Properties of Gases," by Prof. J. J. Thomson, F.R.S.; "A Treatise on Spherical Astronomy," by Sir Robert S. Ball, F.R.S.; "Fossil Plants, a Manual for Students of Botany and Geology," by A. C. Seward, F.R.S., vol. ii.; "A Primer of Botany," by F. F. Blackman; "A Primer of Geology," by J. E. Marr, F.R.S.; "Immunity in Infectious Diseases," by Prof. É. Metchnikoff, authorised English translation by F. G. Binnie, illustrated; "Index Nominum Animalium," compiled by C. D. Sherborn under the supervision of a Committee appointed by the British Association and with the support of the British Association, the Royal Society and the Zoological Society, vol. i. (1758–1800); "Zoological Results based on Material from New Britain, New Guinea, Loyalty Islands and elsewhere, collected during the years 1895, 1896 and 1897," by Dr. A. Willey, part vii. Conclusion; "Reports of the Anthropological Expedition to Torres Straits by the members of the Expedition," edited by Dr. A. C. Haddon, F.R.S. (it is expected that the work will be completed in five volumes); "Fauna Hawaiiensis, or the Zoology of the Sandwich Islands: being results of the Explorations instituted by the Joint Committee appointed by the Royal Society of London for promoting Natural Knowledge and the British Association for the Advancement of Science, and carried on with the assistance of those bodies and of the Trustees of the Bernice Pauahi Bishop Museum," edited by Dr. D. Sharp, F.R.S.; "The Fauna and Geography of the Maldive and Laccadive Archipelagoes: being the Account of the Work carried on and of the Collections made by an Expedition during the years 1899 and 1900 under the Leadership of J. S. Gardiner," vol. ii. part ii.; "The Geographical Distribution of Diseases," by Dr. F. G. Clemow; "An Introduction to Logic," by W. E. Johnson; "Euclid, Books i.–iii., with Simple Exercises," by R. T. Wright; "An Introduction to Physiography," by W. N. Shaw, F.R.S.; "A Brief History of Geographical Discovery since 1400," by Dr. F. H. H. Guillemard; and a new edition of "Solution and Electrolysis," by W. C. D. Whetham.

Messrs. Cassell and Co., Ltd., give notice of:—"The Ascent of Aconcagua," by Sir W. M. Conway, illustrated; Cassell's "Cyclopædia of Mechanics," edited by P. N. Hasluck, second series, illustrated; "The Automobile: its Construction and Management," translated from Gerard Lavergne's "Manuel Théoretique et Pratique de l'Automobile sur Route," revised and edited by P. N. Hasluck, illustrated.

Messrs. W. and R. Chambers, Ltd., call attention to:—"The Nineteenth Century Series," containing "Medicine, Surgery, and Hygiene in the Century," by Dr. E. H. Stafford; "Progress of India, Japan, and China in the Century," by the Right Hon. Sir R. Temple, Bart., F.R.S.; "Progress of the United States of America in the Century," by Prof. W. P. Trent; "Progress of British Empire in the Century," by J. S. Little; "Progress of Canada in the Century," by J. C. Hopkins; "Progress of Australasia in the Century," by T. A. Coghlan and T. T. Ewing; "Progress of New Zealand in the Century"; "Discoveries and Explorations of the Century," by Prof. C. G. D. Roberts; "Economic and Industrial Progress of the Century," by Dr. H. de B. Gibbins; "Inventions of the Century," by

W. H. Doolittle; "Naval Development of the Century," by Sir N. Barnaby; "Progress of Education in the Century," by J. L. Hughes and Dr. L. R. Klemm; "Progress of Science in the Century," by Prof. J. A. Thomson.

Messrs. Chapman and Hall, Ltd., announce:—"Insects Injurious to Staple Crops," by E. D. Sanderson, and "Power and Power Transmission," by E. W. Kerr.

In the list of books in preparation at the Clarendon Press is the following:—Schimper's "Geography of Plants," authorised translation, by Profs. P. Groom and W. R. Fisher.

In the list of Messrs. A. Constable and Co., Ltd., we notice:—"The Prevention of Disease," by Drs. Bing, Einhorn, Fischl, Flatau and others, translated.

Messrs. Duckworth and Co. have in preparation:—"The Fungus Flora of Europe," by G. Massee.

The list of Mr. W. Engelmann (Leipzig) contains:—"Die Assanierung von Wien," edited by Dr. Th. Weyl, illustrated; "Lehrbuch der Qualitativen Analyse," by Dr. W. Böttger, illustrated; "Pflanzenverbreitung im Hercynischen Florenbezirk," by Prof. O. Drude, illustrated; "Die Eisenkonstruktionen der Ingenieur-Hochbauten," by Prof. M. Foerster; "Über Ahnlichkeiten im Pflanzenreiche," by Prof. F. Hildebrand; "Catalogus Dipterorum," by Dr. C. Kertész, vol. i.; "Die Entwicklung des Gesichtes," by Prof. C. Rabl, i. heft, illustrated; "Chemisches Praktikum," by Dr. A. Wolfrum.

Messrs. R. A. Everett and Co. promise:—"The Care of Old Age," by Dr. D. Walsh.

Mr. Gustav Fischer (Jena) gives notice of:—"Handbuch der Pathogenen Mikro-organismen," edited by Profs. W. Kolle and A. Wassermann, part i., illustrated; "Paläontologie und Descendenzlehre," by Prof. E. Koken; and "Tabellen zur Gesteinskunde," by Prof. G. Linck, illustrated.

The announcements of Messrs. Charles Griffin and Co., Ltd., include:—"Trades' Waste: its Treatment and Utilisation, with Special Reference to the Prevention of Rivers' Pollution," by W. Naylor, illustrated; "Physico-Chemical Tables for the Use of Analysts, Physicists, Chemical Manufacturers, and Scientific Chemists," by J. Castell-Evans, vol. i.:—Chemical Engineering, Physical Chemistry; vol. ii.:—Chemical Physics, Pure and Analytical Chemistry; "Elementary Coal-Mining: for the Use of Students, Miners, and others preparing for Examinations," by G. L. Kerr, illustrated; "Students' Handbook on Paints, Colours, and Varnishes," by G. H. Hurst, illustrated; "A Text-Book of Physics," by Profs. J. H. Poynting, F.R.S., and J. J. Thomson, F.R.S., in 5 volumes, illustrated, volumes on the Properties of Matter, Heat, Light, Magnetism and Electricity; "Gold Seeking in South Africa: a Handbook of Hints for intending Explorers, Prospectors, and Settlers," by T. Kassner, illustrated; "The Metallurgy of Steel," by F. W. Harbord, illustrated; "Diseases of the Organs of Respiration: a Treatise of the Etiology, Pathology, Symptoms, Diagnosis, and Treatment of Diseases of the Lungs and Air Passages," by Dr. S. West, 2 vols., illustrated; "The Work of the Digestive Glands," by Prof. Pawlow (the Nobel Prize Researches in Physiology, 1901), translated by Dr. W. H. Thompson; "Hygiene and Public Health," by Dr. H. W. G. Macleod, illustrated.

Messrs. Hodder and Stoughton promise:—"Arithmetic and Algebra," by J. Davidson ("Self Educator" Series).

Messrs. P. S. King and Son call attention to:—"Sewage Works Analyses," by G. J. Fowler, illustrated; "The Sanitary Inspector's Guide," by H. Lemmoin-Cannon, and a new edition of "Elements of Statistics," by A. L. Bowley.

Mr. John Lane has in hand for appearance in his "Handbooks of Practical Gardening":—"The Book of Vegetables," by G. Wythes; "The Book of the Strawberry," by E. Beckett; and "The Book of Orchids," by W. H. White.

Messrs. Crosby Lockwood and Son will publish:—"The Deep-Level Mines of the Rand and their Future Development, Considered from the Commercial Point of View," by G. A. Denny, illustrated.

Messrs. Longmans and Co.'s list includes:—"The Natural History of the British Surface-Feeding Ducks," vol. i., by J. G. Millais, illustrated; "Higher Mathematics for Students of Chemistry and Physics, with Special Refrence to Practical Work," by Dr. J. W. Mellor; "Biology (Nature Study, Botany and Zoology)," by Prof. F. E. Lloyd and M. A. Bigelow; "The Steam Turbine," by R. M. Neilson, illustrated; "A Text-Book of Electro-Chemistry," by Prof. S. Arrhenius, translated by Dr. J. McCrae, illustrated; "Assaying and Metallurgical Analysis, for the use of Students, Chemists and Assayers," by E. L. Rhead and Prof. A. H. Sexton; "Calculations in Hydraulic Engineering, a Practical Text-Book for the Use of Students, Draughtsmen, and Engineers," by Prof. T. C. Fidler; "Part II. Calculations in Hydro-Kinetics," illustrated; "A Manual of Surgical Treatment," by Prof. W. W. Cheyne, F.R.S., and Dr. F. F. Burghard, in 6 parts: part vi., sections 1 and 2.

Messrs. Sampson Low and Co., Ltd., give notice of:—"A Manual of Indian Timbers," by J. S. Gamble, F.R.S., illustrated; "Moose Hunting, Salmon Fishing, and other Sketches, and new editions of "Health and Condition in the Active and the Sedentary," by Dr. W. E. Yorke-Davies; "The Nordrach Treatment for Consumption in this Country, how to Cure and Prevent Consumption and other forms of Tuberculosis, together with a General Consideration of the Laws governing Health," by J. A. Gibson.

Messrs. Macmillan and Co., Ltd., announce:—"The Scientific Memoirs of Thomas Henry Huxley," edited by Sir M. Foster, K.C.B., F.R.S., and Prof. E. Ray Lankester, F.R.S., vol. iv.; "The Cambridge Natural History," edited by Dr. S. F. Harmer, F.R.S., and A. E. Shipley; vol. x.:—Mammals, by F. E. Beddard, F.R.S., illustrated; "Philosophy: its Scope and Relations," a course of introductory lectures by the late Prof. Henry Sidgwick; "The Climates and Baths of Great Britain, being the Report of a Committee of the Royal Medical and Chirurgical Society of London," vol. ii.:—The Midland Counties and Ireland; "Outlines of Metaphysics," by Prof. J. S. Mackenzie; "Metallography," by A. H. Hiorns; "Injuries," by Dr. Wharton Hood; "A Key to Euclid's Elements of Geometry," by C. Smith and Dr. Sophie Bryant; "Inorganic Chemistry," by Prof. W. Ostwald, translated; "Light for Students," by E. Edser; Macmillan's "Geography of Africa"; and new editions of "On a Method of Predicting by Graphical Construction Occultations of Stars by the Moon and Solar Eclipses for any given Place, together with more Rigorous Methods of Reduction for the accurate Calculation of Longitude," by Dr. F. C. Penrose, F.R.S.; "Treatise on Kinematics and Dynamics," by Prof. J. G. Macgregor, F.R.S.; "Essays in Historical Chemistry," by Dr. T. E. Thorpe, F.R.S.; "Practical Botany for Beginners," by Prof. F. O. Bower, F.R.S.

In Messrs. Methuen and Co.'s list we notice:—"A Junior Chemistry," by A. E. Tyler, illustrated.

Mr. Murray's list includes:—"Ten Thousand Miles in Persia: a Record of Eight Years' Constant Travel in Eastern and Southern Iran," by Major P. M. Sykes, illustrated; "The Harveian Oration," delivered before the Royal College of Physicians of London, October 18, 1901, by Dr. Norman Moore; "Heredity," by Prof. J. A. Thomson (the "Progressive Science Series"); "The Soil," by A. D. Hall; "Dangerous Trades and Occupational Diseases," by a number of Experts, edited by Dr. T. Oliver; "Telegraphs and Telephones," by Sir W. H. Preece, K.C.B., F.R.S.; "Electric Wiremen's Work," by W. C. Clinton; "Village Lectures on Popular Science," by the Rev. Canon Ovenden, 2 vols.; "Introduction to Philosophy," by Dr. S. Rappoport; "The Calculus for Artisans," by Prof. O. Henrici, F.R.S.; "Animism: a Treatise on the Natural History of Religion" (based on the Gifford Lectures delivered in Aberdeen in 1889–90 and 1890–91), by Prof. E. B. Tylor, F.R.S., illustrated; "The Basis of Social Relations: a Study in Ethnic Psychology," by Dr. D. G. Brinton; and a cheap edition of "Charles Darwin: his Life, told in an Autobiographical Chapter, and in a Selected Series of his Published Letters," edited by his son, F. Darwin, F.R.S.

Messrs. George Newnes, Ltd., will issue in the "Library of Useful Stories":—"The Story of Euclid," by W. B. Frankland; "The Story of Lost England," by Beckles Willson; "The Story of Music," by F. J. Crowest; "The Story of Animal Life," by W. B. Lindsay.

Messrs. S. W. Partridge and Co. announce:—"Cameos from Nature," by C. N. Williamson, illustrated; and "The Conquest of the Air: a Romance of Aërial Navigation," by J. Alexander.

Messrs. Kegan Paul and Co., Ltd., promise:—"Variations in Plants and Animals," by H. W. Vernon, illustrated; and a new edition of "Physiological and Pathological Chemistry, in Twenty-one Lectures for Physicians and Students," by Prof. G. Bunge, translated by Florence Starling.

In the list of Messrs. C. Arthur Pearson, Ltd., we observe:—"The Giant Fish of Florida," by J. Turner-Turner, illustrated;

and "Home Pets, Furred and Feathered," by M. Fermor, illustrated.

In the list of Messrs. G. P. Putnam's Sons we find:—"American Flora," by F. S. Matthews, illustrated; and "The Cañons of the Colorado," by F. S. Dellenbaug, illustrated.

The Walter Scott Publishing Company, Ltd., will publish in the "Contemporary Science Series":—"The Making of Citizens," by R. E. Hughes.

Messrs. Seeley and Co., Ltd., will issue:—"The Naturalist on the Thames," by C. J. Cornish, illustrated.

Messrs. Swan Sonnenschein and Co., Ltd., announce:—"Avenues to Health," by E. H. Miles, illustrated; "A Treatise on Psychology," by G. Spiller; "Human Evolution: an Inductive Study of Man," by Dr. G. R. Hall; "Studies in Political and Social Ethics," by Prof. D. G. Ritchie; "Elementary Geometry, being a new Treatment of the Subject Matter of Euclid (Books i.–iv.), specially adapted for use in Schools," by J. Elliott; and new editions of:—"Wundt's Ethics," vol. i.:—The Facts of the Moral Life, translated by Profs. Gulliver and Titchener; "On Human Nature: and other Essays," by A. Schopenhauer, translated by T. B. Saunders; "A Practical Pocket-Book of Photography," by Dr. E. Vogel, translated and edited by E. C. Conrad, illustrated; "The Dynamo: How Made and How Used," by S. R. Bottone; and "School Hygiene," by Dr. A. Newsholme and W. C. C. Pakes, illustrated.

The University Tutorial Press, Ltd., announce:—"First Stage Practical Plane and Solid Geometry," by G. F. Brun; "First Stage Machine Construction and Drawing," by J. H. Dales; "Mathematics, First Stage," edited by Dr. W. Briggs; "Physiology, First Stage—Section 1," "Physiography," "Hygiene, Advanced," by A. E. Ikin and R. A. Lyster; "First Stage Applied Mechanics"; "First Stage Organic Chemistry (Theoretical)," by R. A. Lyster; "First Stage Mining"; "First Stage Steam"; "Section I. Hygiene," by R. A. Lyster; and "Euclid, Books V., VI., and XI.," by R. Deakin.

Mr. Fisher Unwin gives notice of:—"Indonesian Art. Selected Specimens of Ancient and Modern Art and Handiwork from the Indian Archipelago," by C. M. Pleyte, illustrated; and "Sand-Buried Cities in Turkestan," by M. A. Stein.

Messrs. Whittaker and Co.'s announcements comprise:—"Electric Traction," by J. H. Rider; "Electric Lighting and Power Distribution," by W. P. Maycock, vol. ii.; "Galvanic Batteries," by S. R. Bottone: Whittaker's "Electrical Engineers' Pocket-Book," edited by K. Edgcumbe; "Recent Development in Locomotive Practice," by C. J. B. Cooke; "Inspection of Railway Material," by G. R. Bodmer; "Pipes and Tubes," by P. R. Bjorling; and new editions of:—"Surveying and Surveying Instruments," by G. A. T. Middleton; "Electric Lighting and Power Distribution," by W. P. Maycock, vol. i.; "Electric Wiring, Fittings, Switches and Lamps," by W. P. Maycock; and "Electric Influence Machines," by J. Gray.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Prof. Tylor has resigned the office of keeper of the University Museum, which he has held since the death of Prof. Henry Smith in 1883. He will retain his leadership in anthropology. Prof. Tylor's magnificent gifts of totemistic objects to the Museum will remain as tokens of the great interest which he has taken in the welfare of the institution with which his more immediate connection will now cease.

At a meeting of the Junior Scientific Club on Wednesday, March 5, papers were read by Mr. H. D. Davis (Balliol) on snake poisons, and by Mr. J. Phelps (Trinity) on the boiling points of solutions.

CAMBRIDGE.—Mr. T. H. Havelock, of St. John's College, has been elected to the Isaac Newton studentship in physical astronomy. Mr. Havelock and Mr. J. E. Wright (senior wrangler 1900), of Trinity, are the Smith's prizemen of the year.

The Allen studentship is awarded to Mr. F. N. Hales, Trinity, for research in psychophysics.

The Balfour studentship in animal morphology is awarded to Mr. J. S. Budgett, Trinity.

The General Board of Studies propose to re-establish the office of assistant to the superintendent of the Museum of Zoology with a view to the arrangement of the collections.

MR. R. A. S. REDMAYNE has been appointed professor of mining in the University of Birmingham, and Mr. Thomas Turner professor of metallurgy. Mr. Redmayne is resident manager of the Seaton Delaval Collieries in Northumberland, and Mr. Turner has for several years been director of technical instruction to the Staffordshire County Council.

THE sum of 25,000*l.* has been given by Mr. William Johnston, shipowner of Liverpool, for furthering the university movement in that city. The money will be devoted, in accordance with the wishes of the donor, to promote research in pathology and physiology. The 25,000*l.* is divided as follows:—10,000*l.* is allocated to found a chair of chemical biology, 6000*l.* at 5 per cent. interest to endow permanently three research fellowships of 100*l.* a year each. Of these fellowships one is held by a medical graduate of a colonial university, a second by a graduate of medicine of the United States, and a third by a research student in gynæcology. The remaining 9000*l.* is to be spent in building a laboratory adjoining the Thompson Yates laboratories, to accommodate the tropical school, the professor of chemical biology, experimental medicine, comparative pathology, and serum research department.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 6.—"The Density and Coefficient of Cubical Expansion of Ice." By J. H. Vincent, D.Sc., B.A., St. John's College, Cambridge. Communicated by Prof. J. J. Thomson, F.R.S.

February 20.—"Note on the Anomalous Dispersion of Sodium Vapour." By W. H. Julius, Professor of Physics in the University of Utrecht. Communicated by C. Vernon Boys, F.R.S.

"On the Physics and Physiology of the Protoplasmic Streaming in Plants." By Alfred J. Ewart, B.Sc. (Oxon), D.Sc. (Lond.), Ph.D., F.L.S., Lecturer on Botany in the Birmingham Technical Institute. Communicated by Francis Gotch, D.Sc., F.R.S.

February 27.—"Note on the Discovery of a New Trypanosoma." By D. Bruce, F.R.S., Lieut.-Colonel., R.A.M.C.

The author received from South Africa specimens of blood taken from cattle which contain a new species of Trypanosoma.

This new species can be at once distinguished from the Trypanosomas of Surra, tse-tse fly disease, or rat by its larger size, it being almost twice as large as any of the others. In general appearance it conforms closely to the others in possessing an oval protoplasmic body, a longitudinal fin-like membrane, and a single flagellum.

This new Trypanosoma was lately discovered by Dr. A. Theiler, who is in charge of the bacteriological laboratory of the Medical Officer of Health, Pretoria, Transvaal.

He states that at first he was under the impression that he had merely hit against the familiar Trypanosama of tse-tse fly disease. He, however, was struck by its larger size, and tried a few inoculation experiments. He found that the new Trypanosoma only infects cattle. Horses, dogs, goats, rabbits and guinea-pigs are all immune, neither showing symptoms nor the presence of the parasites in the blood. With the same blood he infected two calves, which showed distinct febrile reaction, and at the same time the parasites appeared in the blood.

He found the parasite for the first time in the blood of a young ox which had just recovered from an attack of rinderpest, and since then has successfully inoculated calves from two other cattle.

He describes the disease as an acute pernicious anæmia with grave blood changes, a general anæmia without deformation of the elements of the blood, or, lastly, only a slight fever, and that there exists a natural immunity in cattle against this Trypanosoma.

He is of opinion that this disease is the same as that attributed by Dr. Kolle—who studied rinderpest in South Africa with Koch during the last outbreak—to bovine malaria. Dr. Kolle overlooked the Trypanosoma, saw that the disease was infectious, and thought he observed endoglobular parasites and pigment in the red blood corpuscles.

As this discovery seems to be an interesting one, and as

Dr. Theiler deserves great credit for the observation, it is proposed that this Trypanosoma be named after the discoverer *Trypanosoma Theileri.*

Royal Microscopical Society, February 19.—Mr. W. Carruthers, F.R.S., vice-president, in the chair.—The chairman directed attention to an interesting exhibition, by Mr. Conrad Beck, of typical bacteria.—The secretary, in the absence of the author, read a paper by Mr. Nelson on polarising with the microscope, wherein the use of tourmalines was advocated. One tourmaline, of a smoky tint, with the slightest dash of pink, free from veins or specks, and not less than $\frac{1}{4}$-inch in diameter, should be mounted in a cap to fit over the eye-piece. The other tourmaline might be of the ordinary yellow-green variety, but larger, about $\frac{6}{10} \times \frac{6}{10}$ inch, mounted in a metal screen, $2\frac{3}{4} \times 3\frac{1}{2}$ inches, so as to exclude all light not passing through the tourmaline. This screen is to be placed in front of and close to the lamp chimney. Any form of substage condenser can be used with this new arrangement of tourmalines, with the exception of apochromatic condensers, which should not be used in polariscope work because the fluorite used in their construction itself polarises. The images obtained by this new method will be just as critical as those in a microscope where no polariscope is used. The paper concluded with an explanation of the advantages obtained in the adoption of the arrangement in the investigation of phenomena due to the interference of polarised light. Mr. Karop thought it would be a great advantage if a tourmaline prism could be rendered effective, as Nicol's prisms were expensive; he thought, however, that a sufficiently large piece of flawless tourmaline would be as expensive as a Nicol's prism.

PARIS.

Academy of Sciences, March 3.—M. Bouquet de la Grye in the chair.—On an antique vase found at Abou-Roach, by M. Berthelot. Contrary to expectation, this vase proved to be not metallic, but appears to have been prepared by the reaction between a fine sand and a mixture of litharge and common salt. —Researches on the silicide of calcium, by MM. H. Moissan and W. Dilthey. As the accounts of the properties of calcium silicide given by Wöhler, Chalmot and Jacobs are contradictory, the authors undertook its reinvestigation. It is obtained by the reaction of lime and silicon at the temperature of the electric furnace, but since calcium silicide is readily oxidised by fused lime it is necessary to keep the silicon in excess. The silicide obtained in this way contained only silicon as impurity, and in one case this amounted to only 1 per cent. Calcium silicide acts very slowly upon water, the reaction being complete only after some months. Hydrogen is the only gas evolved, no gaseous compound of silicon being produced. Hydrochloric acid attacks it more rapidly, hydrogen again being the only gas produced.—On the crystallisation of iron peroxide, by M. Alfred Ditte. The conversion of oxide of iron into the crystallised form by ignition of sulphate of iron with salt is due to the combined action of the vapours of ferric chloride, hydrochloric acid and sodium chloride. The action takes place still more readily in the presence of fluorides, but in this case the oxide is liable to be contaminated by traces of insoluble fluorine compounds.—On a new Trypanosoma of the Bovidæ, by M. A. Laveran. The new species is classified as *Tr. Theileri*, and is clearly distinguished from *Tr. Brucei* by the fact that the latter is inoculable into a large number of mammals, whilst the new species appears to be special to the Bovidæ. It is pathogenic, producing anæmia either with or without fever. During the course of the fever the parasites may be found in the blood for some weeks. Occasionally there is pernicious anæmia with a rapid destruction of the red corpuscles, leading quickly to a fatal issue.—New syntheses of methane, by MM. Paul Sabatier and J. B. Senderens (see p. 446).—Methane is produced by the action of reduced nickel upon mixtures of hydrogen with carbon monoxide or dioxide.—On the lines of maximum decrease of moduli and algebraic or transcendental equations, by M. Edmond Maillet.—On entire functions and the transcendental meromorphs discovered by M. Painlève, by M. Pierre Boutroux. —The cooling power of air at high pressures and of air in motion, by M. P. Compan. The formula expressing the law of cooling as given by Dulong and Petit has been verified for pressures below atmospheric. The author proposed to see how far this formula was valid when the pressures are higher than atmospheric, when the hot body cools in a chamber of indefinite shape, and when the air is in motion. The constants of Dulong and Petit were found to hold up to pressures of six atmospheres, and were also found to remain unchanged when the cooling took place in the open instead of inside a spherical envelope. The cooling effect of air in motion was found to be represented by the formula $kt\sqrt{u}$, where u is the velocity of translation of the air and t the excess of temperature.—On an electrostatic relay, by M. V. Crémieu. A description of a relay which is capable of automatically regulating the potential of the charge on a condenser.—On the use of the capillary electrometer for measuring the true differences of potential at the contact of amalgams and electrolytes, by M. Lucien Poincaré. A reclamation of priority against M. P. Boley.—On the search for a Hertzian radiation emanating from the sun, by MM. H. Deslandres and Décombe. A discussion as to the best mode of attacking the problem of determining whether any of the Hertzian radiations from the sun reach the lower regions of the earth's atmosphere. The conclusion is drawn that the apparatus for this purpose should be set up in observatories devoted to physical astronomy, side by side with the apparatus for the study of the sun and its atmosphere. A lengthy series of observations will probably be necessary before the question can be finally decided.—The explanation of some celestial phenomena by means of the Hertzian waves, by M. Charles Nordmann. The author draws the conclusion that the sun must emit Hertzian waves, this emission being particularly intense in the regions where violent superficial eruptions are produced and at those times when the intensity of the eruptions is at a maximum, that is to say, in the region of the spots and faculæ and at the moment of maximum solar activity. This view is then applied to the explanation of the form of the solar corona and the spectra of comets. It is claimed for this theory that it is contradicted by no facts, and renders a complete account of many different and otherwise inexplicable phenomena.—On the recombination of the ions in gases, by M. P. Langevin. In a previous note a theory has been given of a method permitting of the direct measurement of the coefficient of recombination of positive and negative ions. The experimental part of the work is given in the present paper. It is shown that the thickness of the gaseous layer and the strength of field may be varied within wide limits without affecting the constancy of this coefficient, which remains between 0·26 and 0·28, a value which coincides with the determination of the same coefficient by Townsend made by an entirely different method. From this it would appear that in air at the ordinary pressure there is about one recombination for every four collisions between ions of opposite signs.—The magnetostriction of nickel steels, by MM. H. Nagaoka and K. Honda.—Remarks on the researches of MM. Nagaoka and Honda, by M. C. E. Guillaume.—On the expansion of steels at high temperatures, by MM. Georges Charpy and Louis Grenet. The coefficients of expansion, which increase with temperature, remain almost exactly equal for the different steels, the percentage of carbon in which varies from 0·03 to 3·5.—The specific heat and atomic weight of vanadium, by MM. C. Matignon and E. Monnet. A crystalline compound of aluminium and vanadium, AlVa, was prepared, and the mean specific heat as determined in this and in a ferro-vanadium was 0·1245, which gives an atomic heat of 6·35 if the atomic weight be taken as 51.—On some thallium combinations, by M. V. Thomas.—On dioxytariric and ketotariric acids, by M. Arnaud.—On the products of condensation of tetramethyldiamidobenzhydrol with some primary aromatic amines in which the para-position is occupied, by MM. A. Guyot and M. Granderye.—New reactions of organometallic derivatives, by M. E. E. Blaise. If the crude product of the reaction of magnesium upon an ethereal solution of an alkyl iodide is treated with ethylene oxide, the splitting of the magnesium compound takes place for the most part in a different manner from the syntheses already published, the main product being ethylene bromhydrin. At the same time, a small quantity of the expected primary alcohol containing two atoms of carbon more than the original alkyl group is also obtained.—The action of sulphides, sulphites and hyposulphites upon nitro-derivatives of azo-colouring matters, by MM. Rosenstiehl and Suais.—Compounds of alcohol with the chlorides of manganese and cobalt, by M. F. Bourion.—Some facts in opposition to the application without reserve of the laws of osmosis to red blood corpuscles, by MM. H. Stassano and F. Billon. It is generally admitted without question, as a consequence of the laws of osmosis, that the volume of a red corpuscle varies inversely with the

concentration of the solution. Observations are given showing that this principle does not completely express the actual phenomena.—Volume in urology, by M. J. Winter.—The employment of the electric arc in iron in phototherapy, by MM. André Broca and Alfred Chatin.—*Pachypodium Rutenbergianum*, a Madagascan textile plant, by M. Henri Jumelle.—On some rocky veins which traverse the dunite ground mass of Koswinsky, by M. L. Duparc.

DIARY OF SOCIETIES.

THURSDAY, MARCH 13.

ROYAL SOCIETY, at 4.30.—Croonian Lecture, on Certain Chemical and Physical Properties of Hæmoglobin: Prof. A. Gamgee, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Adjourned discussion on the following papers:—Electric Shock and Legislation thereon: Major-General C. E. Webber, C.B., R.E.—Electric Shocks: F. B. Aspinall.—Electric Shocks at 500 volts: A. P. Trotter.

MATHEMATICAL SOCIETY, at 5.30.—The Theory of Cauchy's Principal values (III.): Mr. G. H. Hardy.—The Solutions of a System of Linear Congruences: Rev. J. Cullen.—Algebraical Connection between Zonal Harmonics of Orders differing by an Integer: R. Hargreaves.—On Quadrature Formulæ: J. Buchanan.

SOCIETY OF ARTS (Indian Section), at 4.30.—The Indian Famine of 1899, and the Measures taken to meet It: T. W. Holderness.

FRIDAY, MARCH 14.

ROYAL INSTITUTION, at 9.—Magnetism in Transitu: Prof. S. P. Thompson, F.R.S.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Note on the Green Flash: T. W. Backhouse.—The Flash Spectrum, Sumatra Eclipse, 1901: S. A. Mitchell.—Observations of Nova Cygni (1876) made with the 40-inch Refractor of the Yerkes Observatory: E. E. Barnard.—Anomalous Occultations of Stars by the Moon: G. W. Hough.—The Duration of Totality at Naval-moral, 1900: C. T. Whitmell.—Note on Prof. Turner's Recent Paper on Photographic Surveying: H. G. Fourcade.—The Magnitude of η-Argûs, 1900–1902: R. T. A. Innes.—On the Variation of S. Carinæ: A. W. Roberts.—Σ 484 and 485, and two pairs: Rev. T. E. Espin.—Double Star Observations. 1899–1901: W. H. Maw.—New Variable Stars found during the Measurements for the Astrographic Catalogue: Royal Observatory, Greenwich.—Results of Micrometer Measures of Double Stars made with the 28-inch refractor: Royal Observatory, Greenwich.—*Promised papers.*—Mean Areas and Heliographic Latitudes of Sun-spots in the Year 1901: Royal Observatory, Greenwich.—Proper Motion of Nova Persei: Royal Observatory, Greenwich.—On the Images formed by a Parabolic Mirror. First paper:—The Geometrical Theory: H. C. Plummer.

MALACOLOGICAL SOCIETY, at 8.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Use of Long Steel Wires in Surveying: H. J. Deane.

PHYSICAL SOCIETY, at 5.—The Thermal Expansion of Porcelain: A. E. Tutton, F.R.S.—On the Temperature Variation of the Electrical Resistance of Pure Metals, and Allied Matters: W. Williams.—A Suspected Case of the Electrical Resonance of Minute Metal Particles for Light Waves. A New Type of Absorption: Prof. R. W. Wood.

SATURDAY, MARCH 15.

ROYAL INSTITUTION, at 3.—Some Electrical Developments: Lord Rayleigh, F.R.S.

MONDAY, MARCH 17.

VICTORIA INSTITUTE, at 4.30.—Adaptation and Selection in Nature, and their Bearing on the Evidence of Design: Dr. W. Kidd.

SOCIETY OF ARTS, at 8.—Photography applied to Illustration and Printing: J. D. Geddes.

TUESDAY, MARCH 18.

ROYAL INSTITUTION, at 3.—Recent Researches on Protective Resemblance, Warning Colours and Mimicry in Insects: Prof. E. B. Poulton, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed*:—Electrical Traction on Railways: W. M. Mordey and B. M. Jenkin. Papers will be read:—The Greenwich Footway-Tunnel: W. Copperthwaite.—Subaqueous Tunnelling through the Thames Gravel, Baker Street and Waterloo Railway: A. H. Haigh.

ZOOLOGICAL SOCIETY, at 8.30.—The Evolution of Horns and Antlers: Dr. Hans Gadow, F.R.S.—Notes on the Transformations of some South-African Lepidoptera: Lt.-Col. J. M. Fawcett.—On a new Stridulating-Organ in a Scorpion: R. I. Pocock.

ROYAL STATISTICAL SOCIETY, at 5.

WEDNESDAY, MARCH 19.

CHEMICAL SOCIETY, at 5.30.—The Absorption Spectra of Metallic Nitrates, Part I.: W. N. Hartley.—A Method of Determining the Ratio of Distribution of a Base between Two Acids: H. M. Dawson and F. E. Grant.—On the Molecular Complexity of Acetic Acid in Chloroform Solution: H. M. Dawson.—On the Existence of Polyiodides in Nitrobenzene Solution: H. M. Dawson and R. Gawler.—Nitrogen Chlorides containing the Propionyl Groups: F. D. Chattaway.—Derivatives of a-Aminocamphoroxime: A. Lapworth and A. W. Harvey.—Preparation of Sulphamide from Ammonium Amidosulphite: E. Divers and M. Ogawa.—Hypoiodous Acid: R. L. Taylor.

SOCIETY OF ARTS, at 8.—Electric Traction. London's Tubes, Trams, and Trains: J. C. Robinson.

ROYAL MICROSCOPICAL SOCIETY, at 7.30.—Exhibition of Foraminifera: A. Earland.

ENTOMOLOGICAL SOCIETY, at 8.—Notes on Some Cases of Seasonal Dimorphism in Butterflies; with an Account of Experiments made by Mr. Guy A. K. Marshall: Dr. F. A. Dixey.—Mimicry illustrated by the Sanger Shepherd Three Colour Process: Prof. E. B. Poulton, F.R.S.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—La Lune mange les Nuages. A Note on the Thermal Relations of Floating Clouds: W. N. Shaw, F.R.S.—The Prevalence of Gales on the Coasts of the British Islands during the Thirty Years 1871–1900: F. J. Brodie.

THURSDAY, MARCH 20.

ROYAL SOCIETY, at 4.30.—*Probable papers*:—Development of the Layers of the Retina in the Chick after the Formation of the Optic Cup: J. Cameron.—On a Peculiarity of the Cerebral Commissures in certain Marsupialia, not hitherto recognised as a Distinctive Feature of the Diprotodontia: Prof. G. Elliot Smith.—The Classification of the Elements: Prof. H. E. Armstrong, F.R.S.—On a Throw-Testing Machine for Reversals of Mean Stress: Prof. Osborne Reynolds, F.R.S., and J. H. Smith.—On the Equilibrium of Rotating Liquid Cylinders: J. H. Jeans.—A Portable Telemeter, or Range-finder: Prof. G. Forbes, F.R.S.

LINNEAN SOCIETY, at 8.—Electric Response in Ordinary Plants under Mechanical Stimulus: Prof. J. C. Bose.—On the Fruit of *Melocarina bambusoides*, Trin., an Exalbuminous Grass: Dr. O. Stapf.—On Malacostraca from the Red Sea Collected by Dr. H. O. Forbes: Messrs. Alfred O. Walker and Andrew Scott.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Problems of Electric Railways: J. Swinburne and W. R. Cooper.

FRIDAY, MARCH 21.

ROYAL INSTITUTION, at 9.—Recent Developments in Colouring Matters. (In English): Prof. Otto N. Witt.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Fencing of Steam and Gas-Engines: H. D. Marshall.—Fencing or Guarding Machinery used in Textile Factories: S. R. Platt.—Protection of Lift-shafts, and Safety Devices in connection with Lift-Doors and Controlling Gear: H. C. Walker.—Guarding Machine Tools: W. H. Johnson.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Infantile Mortality in the Tropics Dr. Daniels.

SATURDAY, MARCH 22.

ROYAL INSTITUTION, at 3.—Some Electrical Developments: Lord Rayleigh, F.R.S.

ESSEX FIELD CLUB (Essex Museum of Natural History, Stratford), at 6.30.—Annual Meeting. The Presidential Address will be delivered by Prof. Meldola, F.R.S., on The Coming of Age of the Essex Field Club, a Record of Local Scientific Work, 1880–1901.

SUPPLEMENT TO "NATURE."

THE PRESENT JUDGED BY THE FUTURE.

Anticipations of the Reaction of Mechanical and Scientific Progress upon Human Life and Thought. By H. G. Wells. Pp. 318. (London: Chapman and Hall. Ltd., 1902.) Price 7*s.* 6*d.*

THIS is a profoundly interesting and suggestive book by a very remarkable man. Mr. Wells was educated at the Royal College of Science; he has a thorough knowledge of, and considerable training in, the great branches of science—physics, chemistry, astronomy, geology and biology. This course of study operated, in the case of Mr. Wells, upon a mind naturally gifted with an extraordinarily vivid imagination and the aptitude for true literary art. In one of his latest works, "Love and Mr. Lewisham," Mr. Wells has told us the story of the struggle for life of a South Kensington student, and for the first time given the Royal College of Science the dignity of literary recognition. But it is by his audacious and fascinating "imaginings" as to the arrival on our planet of the inhabitants of Mars, the strange evolution and changes in the nature of men and the earth's surface as seen a million years hence, the morphology and habits of the inhabitants of the moon, the nocturnal freezing and solidification of its atmosphere, and as to other such topics that Mr. H. G. Wells is best known. The really wonderful range of knowledge shown in these stories, the scientific accuracy of the abundant details, the absolute restraint of the weird histories recounted, within the limits of what scientific criticism must admit as possible—nay, even probable, given the one initial miracle of anyone having and recording experiences of such things—lend a special charm to Mr. Wells' writings wanting in those of all other masters of this kind of literary craft from Swift to Jules Verne. One of his shorter stories, "The Star"—calmly recording in the words of a survivor the approach and passage of a huge meteor which causes the ocean to sweep the land-surface of the earth in all parts to a depth of two hundred feet—is written with such faithful adherence to scientific possibility and such convincing art in narrative that I, for one, am haunted by the conviction that the thing has occurred in past epochs more than once, and may at any time occur again.

The character which Mr. Wells has thus established for himself will necessarily tend to a misunderstanding of the nature of his work recently published under the title "Anticipations." In this book the author is not seeking to amuse us by far-reaching speculation as to remote possibilities. Under the guise of prophecy as to the future, Mr. Wells criticises the present. He imagines that before a hundred years are out (we must all wish this forecast to be realised) there will gradually come into existence

"a naturally and informally organised, educated class, an unprecedented sort of people, a New Republic dominating the world. . . . a new social Hercules that will strangle the serpents of war and national animosity in his cradle . . . a conscious organisation of intelligent and, quite possibly in some cases, wealthy men."

Mr. Wells hopes great things from the cosmopolitanism and intelligence of this coming power. He tells us what the men of this new group will think on various subjects and do in regard to many things, and thus he makes them the vehicle for conveying his righteous indignation and just contempt for a large part of the present ways and beliefs of mankind. It is impossible to do justice in a brief review to a book which deals with nearly every subject under the sun—from motor-cars and cooperative cookery to the struggle for domination among the nations and the essence of religion. Mr. Wells commences his far-reaching survey with a comparatively comfortable chapter on "Locomotion in the Twentieth Century." Special motor tracks and individual motor-cars will to a large extent replace railways. This leads on to the consideration of the "Diffusion of Great Cities." The country will cease to come into the town; the town will spread into the country in proportion as the facilities for locomotion enable a larger and larger area to be in easy touch with the great centres. Then follow chapters on the domestic economy and the relations of class to class—the natural history or bionomics of the social organism in the past, the present and the immediate future of the twentieth century. "War in the Twentieth Century," "The Conflict of Languages" and "Faith, Morals and Public Policy in the Twentieth Century" are the titles of subsequent chapters.

I shall best enable the reader to judge of the manner in which these subjects are treated, and stimulate, I hope, his desire to read Mr. Wells' book by a few quotations.

"The facies of the social fabric has," he says, "changed and—as I hope to make clear—is still changing in a direction from which, without a total destruction and re-birth of that fabric, there can never be any return. The most striking of the new classes to emerge is certainly the share-holding class, the owners of a sort of property new in the world's history. . . . Share property is property that can be owned at any distance and that yields its revenue without thought or care on the part of its proprietor; it is, indeed, absolutely irresponsible property, a thing that no old world property ever was. . . . The shareholder owns the world *de jure*, by the common recognition of the rights of property; and the incumbency of knowledge, management and toil fall entirely to others. He toils not, neither does he spin; he is mechanically released from the penalty of the Fall, he reaps in a still sinful world all the practical benefits of the millennium—without any of its moral limitations."

Among many other ways and habits which are pointed out for improvement in the nascent century, those of house-builders are criticised at some length. Here is a good sample:—

"I find it incredible that there will not be a sweeping revolution in the methods of building during the next century. The erection of a house-wall, come to think of it, is an astonishingly tedious and complex business, the final result exceedingly unsatisfactory. . . . I fail to see the necessity of (and, accordingly, I resent bitterly) all these coral-reef methods. Better walls than this and less life-wasting ways of making them are surely possible. . . . I can dream at last of much more revolutionary affairs, of a thing running to and fro along a temporary rail, that will squeeze out wall as one squeezes paint from a tube, and form its surface with a pat or two as it sets. Moreover, I do not see at all why the walls of small dwelling-houses should be so solid as they are. There still hangs about us the monumental tradition of the

pyramids. It ought to be possible to build sound, portable and habitable houses of felted wire-netting and weather-proofed paper upon a light framework."

Mr. Wells would improve the British workman.

"The average sanitary plumber of to-day in England," he says, "insists upon his position as a mere labourer as though it were some precious thing; he guards himself from improvement as a virtuous woman guards her honour; he works for specifically limited hours and by the hour with specific limitations in the practice of his trade, on the fairly sound assumption that but for that restriction any fool might do plumbing as well as he; whatever he learns he learns from some other plumber during his apprenticeship years—after which he devotes himself to doing the minimum of work in the maximum of time until his brief excursion into this mysterious universe is over."

He has not much respect for the House of Commons.

"Even the physical conditions under which the House of Commons meets and plays at Government are ridiculously obsolete. Every disputable point is settled by a division; a bell rings, there is shouting and running, the members come blundering into the chamber and sort themselves with much loutish shuffling and shoving into the division lobbies. They are counted, as illiterate farmers count sheep; amidst much fuss and confusion they return to their places and the tellers vociferate the result. The waste of time over these antics is enormous, and they are often repeated many times in an evening."

Our author traces the origin of the modern democracy or democratic quasi-monarchy. He has a wholesome contempt for the mode of Government it has produced and the conduct of affairs by party representatives. Every such Government conducts its affairs, he says,

"as though there were no such thing as special knowledge or practical education. The utmost recognition it affords to the man who has taken the pains to know, and specifically to do, is occasionally to consult him upon specific points and override his councils in its ampler wisdom, or to entrust to him some otherwise impossible duty under circumstances of extreme limitation. The man of special equipment is treated always as if he were some sort of curious performing animal."

Of war, Mr. Wells has much to say which is very important and, indeed, should be read, side by side, with the passionate appeal of a similar tendency recently made by Mr. Rudyard Kipling in his "Islanders."

"War," he tells us, "in the past was a thing of days and heroisms; battles and campaigns rested in the hand of the great commander; he stood out against the sky, picturesquely on horseback, visibly controlling it all. War in the future will be a question of preparation, of long years of foresight and disciplined imagination."

The picture given below is a fine sample of Mr. Wells' style and matter:—

"There will be first of all the coming of the war, the wave of excitement, the belligerent shouting of the unemployed inefficients, the flag-waving, the secret doubts, the eagerness for hopeful news, the impatience of the warning voice. I seem to see, almost as if he were symbolic, the grey old general—the general who learnt his art of war away in the vanished nineteenth century, the altogether too elderly general with his epaulettes and decorations, his uniform that has still its historical value, his spurs and his sword—riding along on his obsolete horse by the side of his doomed column. Above all things he is a gentleman—and the column looks at him lovingly with its countless boys' faces, and the boys' eyes are infinitely trustful, for he has won battles in the old time. They will believe in him to the end. They have been brought up in their schools to believe in him and his class, their mothers have mingled respect for the gentlefolk with the simple doctrines of their faith, their first lesson on entering the army was the salute. The 'smart' helmets His Majesty, or some such unqualified person, chose for them lie hotly on their young brows, and over their shoulders slope their obsolete carelessly-sighted guns. Tramp, tramp, they march, doing what they have been told to do; Religion and the Ratepayer and the Rights of the Parent working through the instrumentality of the Best Club in the world have kept their souls and minds, if not untainted, at least only harmlessly veneered, with the thinnest sham of training or knowledge. Tramp, tramp, they go, boys who will never be men, rejoicing patriotically in the nation that has thus sent them forth, badly armed, badly clothed, badly led to be killed in some avoidable quarrel by men unseen. And beside them, an absolute stranger to them, a stranger even in habits of speech and thought, and at any rate to be shot with them fairly and squarely, marches the subaltern—the son of the school-burking shareholding class—a slightly taller sort of boy, as ill taught as they are in all that concerns the realities of life, ignorant of how to get food, how to get water, how to keep fever down and strength up, ignorant of his practical equality with the men beside him, carefully trained under a clerical headmaster to use a crib, play cricket rather nicely, look all right whatever happens, believe in his gentility and avoid talking 'shop.' . . . So the gentlemanly old general—the polished drover to the shambles—rides, and his doomed column march by, in this vision that haunts my mind. I cannot foresee what such a force will even attempt to do, against modern weapons. Nothing can happen but the needless and most wasteful and pitiful killing of these poor lads, who make up the infantry battalions, the main class of all European armies to-day, whenever they come against a sanely organised army. There is nowhere they can come in, there is nothing they can do. The scattered invisible marksmen with their supporting guns will shatter their masses, pick them off individually, cover their line of retreat and force them into wholesale surrenders. It will be more like herding sheep than actual fighting. Yet the bitterest and cruellest things will have to happen, thousands and thousands of poor boys will be smashed in all sorts of dreadful ways and given over to every conceivable form of avoidable hardship and painful disease, before the obvious fact that war is no longer a business for half-trained lads in uniform, led by parson-bred sixth form boys and men of pleasure and old men, but an exhaustive demand upon very carefully educated adults for the most strenuous best that is in them, will get its practical recognition."

Our author proceeds to emphasise

"the inexorable tendency in things to make a soldier a skilled and educated man and to link him, in sympathy and organisation, with the engineer and the doctor, and all the continually developing mass of scientifically educated men that the advance of science and mechanism is producing."

He is led to think it not improbable that the present military hierarchy will be left in this country as a sort of ornamental court attendants, and that an entirely new and independent army will be raised and organised on sound business principles.

"Already," he says, "recruiting is falling off. . . . Elementary education has at last raised the intelligence of the British lower classes to a point when the prospect of fighting in distant lands under unsuitably educated British officers of means and gentility with a defective War Office equipment and inferior weapons has lost much of its romantic glamour."

As to education, Mr. Wells holds, and very many, like myself, will agree with him, that "it is increasingly evident that to organise and control public education is beyond the power of a democratic Government."

"Schools alone are of no avail, universities are merely dens of the higher cramming. . . . At present, in Great Britain at least, the headmasters entrusted with the education of the bulk of the influential men of the next decades are conspicuously second-rate men, forced and etiolated creatures, scholarship boys manured with annotated editions, and brought up under and protected from all current illumination by the Kale-pot of the Thirty-nine Articles. Many of them are less capable teachers and even less intelligent men than many Board School teachers."

There is need, Mr. Wells declares, of a new type of school and also of a new type of university,

"something other than a happy fastness for those precociously brilliant creatures—creatures whose brilliance is too often the hectic indication of a constitutional unsoundness of mind—who can 'get in' before the portcullis of the nineteenth birthday falls."

The coming men, those whom Mr. Wells calls the New Republic, will do away with

"the half-educated, unskilled pretenders, professing impossible creeds and propounding ridiculous curricula, to whom the unhappy parents of to-day must needs entrust the intelligences of their children. . . . The windy pretences of 'forming character,' supplying moral training and so forth, under which the educationalist of to-day conceals the fact that he is incapable of his proper task of training, developing and equipping the mind, will no longer be made by the teacher. Nor will the teacher be permitted to subordinate his duties to the entirely irrelevant business of his pupils' sports." Hereafter "the school and college will probably give only the keys and apparatus of thought, a necessary language or so, a sound mathematical training, drawing, a wide and reasoned view of philosophy, some good exercises in dialectics, a training in the use of those stores of fact that science has made. So equipped the young man and young woman will go on to the technical school of their chosen profession and to the criticism of contemporary practice for their special efficiency and to the literature of contemporary thought for their general development."

The value of literature and the great question of the exclusive study of Greek and Latin writers are alluded to thus:—

"After all, in spite of the pretentious impostors who trade upon the claim, literature, contemporary literature, is the breath of civilised life, and those who sincerely think and write the salt of the social body. To mumble over the past, to live on the classics, however splendid, is senility.'

Many readers will find the final chapter the most interesting in this uncompromising book, where religion, morals and philosophy are briefly but frankly touched. The men of the New Republic will be, says Mr. Wells, "religious" men, and we gather that he is one, a forerunner so to speak, of those new men. They will find "an effect of purpose in the totality of things." That is the essence of being "religious" and amounts to "belief in God." They will "presume to no possibility of knowledge of the real being of God." They will reject the conception of God as an omniscient mind as being as impossible as that which presents Him as an omnipresent moving body.

"They will regard the whole of being, within themselves and without, as the sufficient revelation of God to their souls." "The same spacious faith that will render the idea of airing their egotisms in God's presence, through prayer, or of any such quite personal intimacy, absurd, will render the idea of an irascible and punitive Deity ridiculous and incredible." "To believe completely in God" (as these men will believe) "is to believe in the final rightness of all being." "If" (and this is said in comment on Huxley's Romanes lecture) "the universe is non-ethical by our present standards, we must reconsider these standards and reconstruct our ethics."

Mr. Wells declares that no more "shattering" book than the "Essay on Population" by Malthus has ever been or ever will be written. Darwinism, as one outcome of it, has destroyed the basis of old-fashioned doctrines. An outline is given of the religion of the men of the New Republic. They will not seek to discover the final object of the struggle among existences; they will have abandoned the search for ultimates. They will seek God's purpose in the sphere of their activities and desire no more. They will find in themselves a desire, a passion almost, to create and organise, to put in order, to get the maximum result from certain possibilities. These men will hold life to be a privilege and a responsibility, "not a sort of night refuge for base spirits out of the void." They will, accordingly, not punish criminals by inflicting pain, but will apply Nature's own method of improving her stock—the method of killing. And equally they will not encourage or applaud or support by charity (as many persons do at present)

"a mean-spirited, under-sized, diseased little man, quite incapable of earning a decent living even for himself, married to some underfed, ignorant, ill-shaped, plain and diseased little woman and guilty of the lives of ten or twelve ugly ailing children." "All Christian States of to-day are, as a matter of fact, engaged in slave-breeding. It is a result that endears religion and purity to the sweating employer, and leads unimaginative bishops, who have never missed a meal in their lives, and who know nothing of the indescribable bitterness of a handicapped entry into this world, to draw a complacent contrast with irreligious France."

It seems to me that this book should have—even for those whom it cannot fail to offend—more than the interest which attaches to clever fault-finding. It is, truly enough, an unsparing indictment of existing government, society, education, religion and morality, but it contains also a confession of faith and is full of a spirit of hope and a belief in future development. It is a truthful statement of the outlook of a man who has grasped thoroughly the teachings of modern science and who still keeps hope alive in his breast. E. RAY LANKESTER.

MOTOR VEHICLES.

Motor Vehicles and Motors. By W. Worby Beaumont. (Westminster: A. Constable and Co., Ltd., 1900.)

IT is difficult within the limits of an ordinary notice to deal adequately with this huge work of 618 quarto pages. Mr. Beaumont has attempted to give a complete history of all the applications of mechanical methods of propulsion to vehicles running on the highway, and has described almost every motor vehicle of importance which has been put on the road during the past seventy-five years.

He first deals with that part of the history of self-propelled carriages which is prior to the date when Daimler, by his introduction of the internal combustion petroleum spirit-worked motor, enabled designers for the first time to dispense with the complication of a steam boiler. The author considers Daimler's invention marked an entirely new departure, and he is undoubtedly justified in holding this opinion, as within a few years after Daimler's engine had been applied to motor cars they developed so rapidly and were so commonly used in France and Germany that even in England, the country *par excellence* of restrictive legislation, Parliament was compelled during the year 1896 by sheer force of public opinion to pass an Act removing some of the absurd provisions which had up to that time prohibited any attempt to use motor vehicles on highways or in our streets.

This early historical portion, which occupies the first forty-eight pages, is useful, as it brings clearly before us the great success obtained by the early engineers, such as Hancock, Gurney and others, fully seventy-five years ago. We are apt to forget that the adaptation of steam power to road vehicles was made so successful by these men that it is beyond doubt that if they had been left unharassed by interested opposition and legislation the methods of traffic which now prevail would have been greatly modified; that is to say, that instead of the railways being, as they are at present, practically the sole routes along which traffic is carried, there is no doubt that if Hancock and those of his time had been allowed to continue their work, the highways of England would have carried their share of the traffic, the factories of England would not have been concentrated as they are, all of them close to lines of railway, and many other modifications wholly beneficial would have taken place affecting the distribution, health and happiness of our industrial population.

Designers of modern vehicles learn much from the history of the early attempts. It is interesting, for instance, to notice from the illustrations of the early boilers used by Gurney, Summers and Ogle how closely they approached to the instantaneous generator or flash boiler, as it is called, which was reintroduced by Serpollet in 1889.

Mr. Beaumont has introduced a few chapters on the general questions affecting locomotion on highways; he gives comparatively short descriptions of modern steam vehicles and electrically driven vehicles, but the bulk of his work is occupied by a carefully written history of the modern motor car driven by the internal combustion engine which has been developed from Daimler's discovery in 1885. This history, which occupies more than half of the book, commences with Daimler's work and goes on to describe the important modifications introduced by him and by the various French engineers, Panhard, Levassor, Peugeot, De Dion, Mors and others and by the Daimler Co. themselves at their works at Cammstadt. He also describes very fully the alternative line of discovery followed up by Benz which also commenced in 1885.

This description of the development of the modern motor car is so complete and so profusely illustrated by reproductions of photographs, as well as by scale drawings and diagrams, that it ought to be of considerable value to everyone interested in this matter, whether they be engineer designers, patent agents, or a general reader attempting to post himself in this interesting matter. But the value of the work as a book of reference on the motor car is greatly diminished by the very confused arrangement of this descriptive history. The author could have either described the whole of the successive developments in their strict chronological order or he could have described in turn each inventor's line of development, giving dates so as to enable us to know to whom we owe the initiative in each successful step. Instead of this he has commenced by describing the work of Daimler in 1885 and the next succeeding years, and from thence jumped to a description of the Daimler motors as manufactured in 1899. He then describes the work of the French engineers, without stating when or how they took up Daimler's work, and then goes back to Benz and treats his discoveries in fair chronological order, so that it is very difficult for the average reader of Mr. Beaumont to learn how much is due to Daimler and how much to Benz.

As we have said above, the work is magnificently illustrated; as a rule the author gives an illustration reproduced from a photograph showing the external appearance of each vehicle described. This is followed in most cases by a sectional drawing showing the general arrangement and by detailed drawings to scale of the important internal organs. Some of the drawings, the credit of which we learn from the preface must be given to Mr. d'Esterre, such as those of the general arrangements, Figs. 99 and 100, which are the sectional and plan views of the Panhard and Levassor Daimler motor carriage of 6 h.-p. racing type, are marvellous examples of correct draughtsmanship, and it is a pity that these drawings are confined to the limits of a quarto page, as they would well bear enlargement to double their present scale.

The author has made some attempt to group together his descriptions of certain important features of the engine, such as the carburettors and cylinder-cooling arrangements. He here also gives us a kind of essay on driving and steering wheel axles, although these are common to all classes of mechanically propelled vehicles. He completes his survey of the motor vehicle driven by the internal combustion engine by several pages of tables of the economic performances of these engines when using petrol as fuel. We are inclined to believe with him that many of the French tests of the power given out by these motors are not trustworthy, as the duration of the tests was quite insufficient to enable one

to judge whether the cylinder-cooling devices, wearing surfaces, and other matters which ought to be proportionate to the power developed, were in these cases sufficient for their purpose. He further points out that none of the tests given by him give any fair comparison as to the relative power obtainable from motors using light petrol of the specific gravity of 0·68 as compared with the heavy oils having a specific gravity of 0·88. Apart from the increased difficulty of vaporising the heavy oil, the efficiency obtained ought to be proportionate to the weight, and when these oils are used as heating agents, tested by the amount of water evaporated for a given weight of fuel, it is found in practice that this is so, and that the evaporative efficiency does vary with the weight.

His chapter on carburettors or vaporisers is somewhat disappointing. After all, the use of the carburettors is one of the main features which distinguish the modern petrol or heavy oil motor from the gas engine. After describing the two classes of carburettors for light oil, *i.e.* the surface vaporiser and the spray-making vaporiser, he describes a number of varieties of these two forms, without, however, giving any information as to their comparative efficiency or successful use. His conclusions as to the difficulties in using vaporisers heated by the exhaust gases or otherwise which are necessary when heavy oils are used are interesting and in the main correct. This part of the subject is of the greatest interest and importance, as an enormous development in the use of internal combustion engines for heavy vehicles would follow on a satisfactory solution of the problem of vaporising the heavy oils. Although for many years past the heavy oil stationary engine has taken its place as a well-known trustworthy commercial article, the use of heavy oil in the same internal combustion engine in motor cars has turned out to be a problem offering so many difficulties that up to the present hardly any maker of internal combustion engines has dealt with heavy oil with any reasonable degree of success.

One of the best-written chapters in Mr. Beaumont's book is that on electric ignition. This somewhat difficult matter is dealt with very exhaustively and so clearly that a reader need not be an electrical engineer to understand it. The various sources of electric energy which are used to give the spark and the sparking plugs and accessories necessary are, as a whole, correctly and clearly set out. I can hardly think, however, that Figs. 277 and 280, giving the diagram of magnetic field of the Bosch inductor generator, are correct. At the same time, they are scarcely necessary far making clear the author's meaning.

The author here gives at considerable length, not only the main features, but most of the details of construction of the vehicles used by the London Electric Cab Co. which had already proved a failure at the time that he wrote his description. Since that time great advances have been made in the construction of electrically driven vehicles, chiefly in the improvement of the accumulators themselves, so that we believe it has now been ascertained that electrically driven vehicles can now be put on the streets and worked at a very reasonable cost for maintenance; in fact, already the cost for maintenance of the accumulators is less than that of the rubber tyres.

Jenatzy's electrical vehicle, "La Jamais Contente," which attained a speed of 65·8 miles an hour, is described as having accomplished the greatest speed ever reached on a high road, but since that time much higher speeds have been recorded by the Mors and other petrol-driven vehicles during the time of the Paris-Bordeaux and other great French races.

Some space is devoted to the consideration of modern steam vehicles as made by Serpollet and by various American firms, such as Stanley and Whitney. It is to be regretted, however, that the descriptions of the flash boiler used by Serpollet are so very meagre, for undoubtedly this steam generator needs very careful study, as it bids fair to bring steam once more into use as a propelling power for light vehicles. Vehicles of the Stanley, or "locomobile" class as they are now called, are so common in the streets of London that everyone has noticed their satisfactory and quiet running. Mr. Beaumont's description of the "Stanley" vehicle is very complete.

A chapter is devoted to the description of the heavier motor vehicles used for transport of goods, and of which we have heard so much in connection with the Liverpool trials and more recently during the War Office motor-wagon trials at Aldershot. Several of these vehicles are described with considerable minuteness, but the author omits to tell us why it is that up to the present internal combustion engines have not come into use at all largely for these vehicles. Quite at the end of the book we find one or two chapters dealing with matters which are common to all classes of mechanically propelled vehicles, such as questions of vibration, balancing motors and pivoted steering axles. The latter chapter contains several errors, the chief of which are due to careless editing. For instance, in discussing the question of the side rub of wheels on the road on p. 570, we find distance H described as a number of degrees, and the proper angle of the outer wheel is called "a tangent to a curve." Again, in a description of the Peugeot float feed carburettor on p. 162, cock H is said to be for emptying the carburettor, whereas it is well known that it is not used for this purpose, but fulfils the rather important function of admitting any required quantity of air to the carburettor.

Apart from these errors, and several others of the same kind which are certain to be found in a work containing so much matter, the whole of the descriptive part and illustrations may be generally described as excellent. The same cannot be said of chapters iv., v. and vi., which deal with the general questions of road resistance, resistance due to gravity, and power required, air and wind resistance. In these the author has got together a number of tables recording the results of several experimenters on road resistances, which are confusing and contradictory, as he makes no attempt to explain them or reconcile them in any way.

The subjects of air and wind resistances, which are of some importance, are summarily dismissed in one page of thirty-six lines containing a formula, *i.e.* that connecting air pressure and velocity, which is most certainly incorrect. Here, however, the author can hardly be blamed, as this question of wind pressure and air resistance is one of great difficulty. Most of those who have experimented

in the matter during the last few years are not satisfied that the square law holds at all speeds, *i.e.* that the air resistance does not vary as the square of the velocity of the vehicle passing through it; that when bodies of irregular outline are moved through the air the resistance is not as the square of the velocity, but below 1000 feet per minute it probably varies at a lower rate than the square, at or near 1000 feet the square law is fairly correct, above 1000 feet per minute at a higher rate. It is probable that there is a point at which the curve turns over, otherwise it would be difficult to account for the small consumption of petrol on the racing vehicles during the French road races at the very high speeds registered.

Mr. Beaumont's work as a whole will be found a valuable one to those interested in these matters.

THE STELLAR UNIVERSE.

The Stars: a Study of the Universe. By Simon Newcomb. Pp. xi + 332. (London: John Murray, 1901.) Price 6*s.*

IN the consideration of a book such as this contribution to "The Progressive Science Series," it is advisable to ascertain the standard by which it is to be judged. For convenience, three classes of scientific books may be distinguished, each with its own criterion. There are, first of all, the text-books of a more or less didactic character, aiming at putting the student in possession of the salient facts of his subject; then we have the reference books, and in the third class we may place all volumes which aim at presenting aspects of a science in terms which may be appreciated by the lay as well as the scientific reader. Prof. Newcomb's book belongs to the third of these types, for it is intended to convey to cultivated minds a view of the state of knowledge of the various bodies in the stellar universe. The stars are considered individually and collectively in many of their characteristics and relationships, with particular reference to their general properties and the structure of the sidereal heavens.

It would be impossible for a man of science of such distinguished eminence as Prof. Newcomb to produce a book of mediocre quality in all its parts. Several of the chapters in the present volume are original contributions to astronomical knowledge and are not likely to be overlooked in future discussion. As instances we may mention the essays on the distribution of the stars and the statistical studies of proper motion. In the treatment of such subjects as these Prof. Newcomb is *facile princeps*, the result being that good material is selected and satisfactory conclusions are reached. But in the realm of astro-physics he wanders about with less definite aim and purpose, partly trusting to the counsel of friends as to the selection of subjects upon which to concentrate his attention. The result of this eclectic survey is not altogether satisfactory. A wide acquaintance with the new astronomy and a perfectly impartial spirit are rare attributes among writers on celestial science, but they are none the less desirable, and when they are not manifest the deficiency should be pointed out. This we propose to do, if only for the purpose of showing that there are other points of view beside those occupied by Prof. Newcomb.

It is easy to show that the outlook described is not only limited, but also often imperfect. Take, for example, the account of nebulæ. About forty lines have been found in the spectra of these bodies, yet Prof. Newcomb gives the impression that only four are known, namely the blue and violet hydrogen lines and the two characteristic nebular lines. Moreover, he makes the astounding remark that "none of these lines can be certainly identified with those of any terrestrial substance. The supposed matter which produces them has, therefore, been called nebulum." This is almost all that is said of the spectra of nebulæ, and it is an incorrect and incomplete statement of the facts. The suggestion that the lines at wavelengths 4341 and 4861 are due to the hypothetical nebulum has nothing to support it and cannot be taken seriously. For the rest, we can only say that astro-physics has progressed much farther in the knowledge of the lines and origins of nebular spectra than is implied in Prof. Newcomb's paragraph upon the subject.

As the whole question of the nature of nebulæ has to be referred to spectroscopy for an answer, a basis so slender as that described is unable to support a satisfactory edifice. If all that is known of nebular spectra were bounded by the remarks mentioned, the statement that "the light of a nebula does not come from solid matter, but from matter of a gaseous or other attenuated form" might pass muster among the uncritical. But, in addition to the lines of hydrogen and helium and the flutings of carbon, we have evidence of the existence in nebulæ of the metals iron, calcium and possibly magnesium, thus showing that we are not dealing merely with the permanent gases. So far as the spectroscopic evidence is concerned, the hypothesis that nebulæ consist of meteoritic and gaseous matter satisfies the facts better than any other; and even the dynamical objections mentioned are by no means "insuperable," as Prof. Newcomb describes them. Of course, "the amount of light produced by the collision of two such objects [meteorites] is only a minute fraction of the energy lost." But the remainder produces heat which may be sufficient to vaporise some of the constituents of the meteorites engaged, and it must be remembered that gases glow at a low temperature as well as at a high one.

The tendency to accept transcendental temperatures as characteristic of celestial phenomena shows itself in connection with new stars. We have as the cause of the new star of 1866 "an outburst of incandescent hydrogen, giving rise to a volume of flame of such magnitude as to be visible at the vast distance of our system." From what is now known of new stars it is probable that the Nova of 1866 had a spectrum of much the same kind as that shown by the new stars which have been observed in recent years. In any case, the "world on fire" theory is obsolescent, if not obsolete. Nova Aurigæ began the reform, for no detailed observations with modern instruments had been made before its day. Prof. Copeland detected and announced the presence of hydrogen in the spectrum on the first night he observed the star after receiving the postcard from Dr. Anderson announcing the discovery of the object. The spectrum was photographed at South Kensington a few days later, and on February 8, 1892, Sir Norman Lockyer announced to the Royal Society that "the bright lines K, H, *h* and G are

accompanied by dark lines on their more refrangible sides." Substantially the same announcement was made by Prof. Pickering about the same time. These are the facts, but they have been overlooked by Prof. Newcomb, who does not mention Sir Norman Lockyer or Prof. Pickering in connection with the Nova, but gives Profs. Campbell and Vogel the credit of the discovery of the double spectrum, and ascribes to the latter the demonstration of the existence of hydrogen a fortnight after the element had been detected in England. The question of priority is a small matter, but the principle involved is important, namely, that care should be taken in the selection of significant observations by whomsoever they are made. It can scarcely be said that Prof. Newcomb has exercised impartial judgment in this case.

Early observations of the occurrence of bright hydrogen lines in the spectrum of Mira Ceti are overlooked in much the same way as with Nova Aurigæ. Bright hydrogen lines were photographed in the spectrum of this variable star so long ago as 1886, and were observed by Mr. Espin about the same time; yet we read "Campbel found that near the time of maximum, the bright hydrogen line Hγ was very strong and overexposed on all the plates." The disregard of observation of Beta Lyræ is even more unsatisfactory. Prof. Myers's mathematical theory of the constitution of the star's system is described, while the numerous spectroscopic researches relating to the star are scarcely mentioned. The South Kensington photographs indicated long ago the presence of two bodies giving dark-line spectra—one like Rigel and the other like Bellatrix. The shifting bright lines are superposed upon the double-absorption spectrum, and the spectroscopic variations which occur bear a constant relation to the period of the star's changes of lucidity. Prof. Belopolsky's measures of the velocity of the star in the line of sight, and his proof that the radial velocity is zero when the star is passing through the primary and secondary minima, have practically proved that the chief cause of variability is eclipse by such bodies as those mentioned. Why, then, should these established facts be left out of consideration while space is given to mathematical inquiries which have yet to receive spectroscopic confirmation?

The study of these binary and multiple spectroscopic systems has already led to results of deep significance, and Prof. Newcomb devotes some attention to them. In connection with the account of Prof. Vogel's investigations of Algol, however, it is worth remark that the eclipse theory of the variability of the star was practically established by Prof. Pickering by observations of spectroscopic changes before precise measures of the radial velocity were made at Potsdam. Algol is a case of May wedded to December—a fervid body linked to one apparently decaying or dead. In true spectroscopic binaries like Zeta Ursæ Majoris (not Xi Ursæ Majoris, as is stated on p. 167), we have the component stars in more or less the same stage of development. From close binaries of this kind with periods of a day or so it is now possible to pass almost without a gap to the double stars with periods reckoned in centuries. Prof. Newcomb gives eleven years as the shortest period of a telescopic binary, but the star β 883 has a period of only half this length, which brings the two classes of binary systems closer together than he supposes.

Breaches of continuity are usually only apparent, and become filled as knowledge increases. We have passed the days of special creations, and are beginning to see a course of evolution in all natural processes. The biologist has adapted himself to this idea more readily than the astronomer, who looks askance at all attempts to discover a spectroscopic order of evolution in celestial bodies. Prof. Newcomb brings together a number of interesting facts concerning the structure of our universe, but he does not show much relationship between them. Why is it that nebulæ which give bright-line spectra, bright-line stars and new stars are almost exclusively confined to the Milky Way? For though it is true that diffuse nebulæ "are least numerous in the Milky Way and increase in number as we go from it in either direction," it is also true that there are more planetary nebulæ near the Milky Way than in any other part of the heavens. It is reasonable to suppose that there is a large amount of dark meteoritic matter in the region of the Galaxy, as well as a greater depth of stars. Sir Norman Lockyer has suggested this in explanation of the overwhelming number of very faint stars which occur in the Milky Way. Such stars may only be faint because of the partial extinction of light caused by fine particles of matter; so that the same stars would appear brighter if they happened to be nearer the galactic poles. Upon this hypothesis it is possible to explain phenomena which otherwise appear inexplicable; at any rate, it is as worthy of analysis as the "grindstone" theory of the structure of the universe.

It is too much to assert that no extinction or modification of light occurs in space. We can only analyse what reaches us, and it is just as logical to assume the existence of an absorbing medium as it is to neglect a possible cause which, while not contrary to any observed facts, facilitates the explanation of related phenomena. The test of any theory is not so much how it explains one group of facts or phenomena, but how far it admits of general application; and it is because the meteoritic hypothesis satisfies this condition that it claims attention. Most of us will agree with Prof. Newcomb in the remark, "So far as we can judge from the enumeration of the stars in all directions, and from the aspect of the Milky Way, our system is near the centre of the stellar universe." But the argument is nevertheless unsound. It would be just as reasonable for a horse tethered to a stake to conclude that the grass he was able to get at represented all there was in the world. We can only sound the depths of space so far as our instruments permit us, and the facts as to the distribution of stars or other celestial bodies must be considered in relation to others of a spectroscopic character before we are justified in assuming that the sun is situated towards the centre of our universe.

There are many other points in Prof. Newcomb's book which invite discussion, but they cannot be dealt with here. It is worth mention that no account is taken of Prof. Perry's reasons for believing that the sun may have radiated heat for much more than twenty million years, and that the results of studies of photographs of stellar spectra taken at South Kensington are entirely neglected. The misprints we have noticed are *Sirs* A. A. Common and Isaac Roberts (p. iv.), telescopic for spectroscopic (p. 12)

Goodrick for Goodricke (p. 102), Tebbut for Tebbutt (p. 126), Edinborough for Edinburgh (p. 139), and meteoritic theory for meteoritic hypothesis (p. 190). As was remarked at the commencement of this notice, the book presents many interesting problems on subjects with which Prof. Newcomb is familiar, but it leaves the reader still to seek a broad-minded statement of the position of spectroscopic work in connection with the study of the stars. R. A. GREGORY.

PRINCIPLES OF GEOGRAPHY.

Tarr and McMurry's Geographies. Second book, *North America.* Third book, *Europe and other Continents.* By R. S. Tarr and Frank M. McMurry. Pp. xix + 469, and xx + 574. (New York: the Macmillan Company. London: Macmillan and Co., Ltd., 1900 and 1901.) Price 4*s.* 6*d.* each.

THE leading idea of this series, of which the first volume only, that on "Home Geography," has been published in England, is that "Geography treats of the relation between man and the earth—a hill or a lake is worthy of mention only because it bears a relation to us, the men upon the earth; considered by itself it is not a part of geography." Without discussing this notable statement on its merits, we confess to finding its application in these volumes somewhat disappointing. It becomes an attempt to extend the methods of the elementary illustrated geographies to more advanced stages, and necessitates a degree of sketchiness which makes some parts of the books almost unintelligible and others misleading. On pp. 27 and 28 of vol. ii., for example, we find pictures of fur-clad Eskimos and half-naked savages of the tropics to illustrate the difference of temperature in these two latitudes, and only fourteen pages further on we are confronted with a vertical section of the atmosphere showing the complete general circulation. The circulation between the horse latitudes is compared to that caused by a stove in a room, and the rest is dismissed in the sentences, "Being cooled on account of its great height, the air of the anti-trades slowly settles, some of it coming to the surface at about a third of the distance to the poles. There it spreads out, a part continuing on toward the poles, a part returning to the equator as the trade winds." Given the analogy of the stove, what is the intelligent pupil to make of the "part continuing on towards the poles"?

Again, in connection with oceanic circulation, we find drift currents satisfactorily accounted for, but the cause of the many currents which cannot be thus explained is simply passed over. In describing the relation of ocean currents to climate, the authors fall into serious error, and the old story of the "Gulf Stream" carrying "one-half as much heat into the Arctic as reaches it from the direct rays of the sun" reappears once more. All the explanation given of the tides is, "When the sun and moon pull upon the earth, the ocean, being a liquid that can be moved, is drawn slightly out of shape."

The descriptive parts of these books are admirable; in the volume on the United States especially, the physical features, climate, means of transport, industries and commerce are treated with unfailing interest and clearness, and there is abundance of illustration and good maps; but the "physiographic basis" as here set forth—the attempt to account for modern distribution directly from first principles—must suggest to the boy who "sees difficulties" so many questions of which we do not know the answers that he will be apt to distrust the "principles" altogether, while the boy who accepts everything will receive a fatal impression of the simplicity of the universe. It is one of the advantages of geography that continual reference can be made, in teaching, to first principles, but the science is still a long way from the point at which a satisfactory text-book of the kind proposed by the authors can be written.

ELEMENTARY ZOOLOGY.

A Text-book of Zoology. By G. P. Mudge, A.R.C.Sc. Lond. Pp. viii + 416; 100 figures and 2 coloured plates. (London: Edward Arnold, 1901.) Price 7*s.* 6*d.*

THIS aid to the study of zoology differs in plan from most books of similar purpose. After a general introduction on the scope of biology, which will prove, we fear, a heavy meal for beginners, the author discusses (1) the comparative morphology of vertebrates, illustrated by dogfish, frog and rabbit, and by the lancelet (which has naturally a chapter to itself); (2) the morphology of cœlomate invertebrates, illustrated by crayfish, cockroach, freshwater mussel and earthworm; (3) the structure of Hydra as a type of acœlomate diploblastic invertebrates; and (4) the structure of Paramœcium and Amœba as types of Protozoa. Then follow chapters on reproduction and development, heredity and variation.

Mr. Mudge's exposition is clear and accurate, and his terseness is a feat in itself. Perhaps this striving after conciseness has inhibited the author, for while the chapters on heredity and variation, for instance, are vivid and interesting, there are too many pages in the body of the book which read like dull summaries and show no individuality of treatment or expression. Surely some individuality was needed to justify the repetition for the *n*th time of much that may be found in many other books.

We do not think that Mr. Mudge was wise in his choice of a title—"A Text-book of Zoology"—for this ticket is too big for his wares. A text-book of zoology cannot afford to leave out of consideration birds and reptiles, and half of the classes of invertebrates, or to deal so slightly with bionomics. And while we recognise the value of this new aid to the study of zoology in so far as it forces the student to realise what comparative anatomy means, we doubt whether this lesson is rightly learned when only a few types are compared. Thus, to be frank, is there more than practical convenience to justify the time-honoured position of the frog in schemes of comparative morphological study? As a cheap *corpus vile* on which the student may learn to dissect, the frog is useful—almost indispensable—but as a type for the study of the comparative morphology of vertebrates it is one of the most difficult. The figures in the book are clear and useful, but the prominence given to the coloured diagrams of various circulatory systems seems out of perspective.

THURSDAY, MARCH 20, 1902.

REFORM OF THE TEACHING OF MATHEMATICS.

British Association Meeting at Glasgow, 1901. *Discussion on the Teaching of Mathematics, which took place on September* 14 *at a Joint Meeting of two Sections, Section A, Mathematics and Physics, Section L, Education.* Edited by John Perry. Pp. vi + 101. (London: Macmillan and Co., Ltd.) Price 2*s*. net.

PROF. PERRY'S views concerning the teaching of mathematics have been expounded often in the columns of NATURE and elsewhere, and have aroused a great deal of interest. It was a happy idea to bring about a discussion of these views at a joint meeting of the mathematical and educational Sections of the British Association. The report of that discussion has been issued as a separate small volume. It contains the introductory address delivered by Prof. Perry, a specimen syllabus prepared by him for use in training colleges, the discussion that followed the address, written remarks on the subject communicated by several teachers who did not take part in the discussion, and Prof. Perry's reply. The discussion was restricted to what may be called a possible school range of mathematics; the teaching of advanced mathematics at the Universities was scarcely touched upon. As an outcome of the discussion, a committee of the British Association was appointed

"to report upon improvements that might be effected in the teaching of mathematics, in the first instance of elementary mathematics, and upon such means as they think likely to effect such improvements."

The movement thus initiated is important. Many of the more enlightened teachers of mathematics in Britain have long been dissatisfied with the conditions under which they have been compelled to work; and efforts in the direction of reform have been made, in particular by the Association for the Improvement of Geometrical Teaching. The smallness of the results achieved by those efforts is to be traced mainly to the action of the chief examining bodies; but there are not wanting signs that these bodies are now less complacently conservative than they have been in the past. It is earnestly to be hoped that the indicated change of attitude may turn out to be real. The handy publication under notice should be of great assistance to those who are agitating for reform.

The movement is in great part a reaction against the pedantic and unpractical character of the habitual teaching of mathematics in schools. This character belongs both to the methods of presenting particular subjects and to the order in which the subjects, and the parts of the subjects, are studied. The methods and the order now in vogue are not, of course, a system devised purposely; they have been arrived at gradually, and are sanctioned by tradition. The principles of the proposed reform may be stated broadly as follows:—(1) The way for every abstract generalization should be prepared by intelligent practice of comparatively concrete processes, chosen so as to stimulate inquiry; (2) whenever a choice of alternative orders is offered, that order should be preferred which conduces best to the application of mathematics to practical needs. A subsidiary principle of reform would be that all purely artificial and unimportant developments should be omitted. The principles thus stated will not perhaps excite much opposition; yet far-reaching and radical changes would be required to give effect to them. One result that may be expected to follow from such changes would be that the study of the elements of mathematics would become a better preparation than it is at present for the study of the more advanced theories. The mathematics of most of our elementary text-books is felt to be almost as much out of touch with modern mathematics as with everyday life. This conviction has had some share in promoting the movement in favour of change.

As regards geometry, the thoroughgoing adoption of the above-stated principles of reform would lead in the first place to the introduction of courses of practical work in drawing and measuring, which would precede and accompany the study of demonstrative geometry; and it would lead in the second place to a great simplification of that study. That simplification would consist partly in the abandonment of Euclid's "Elements" as a text-book. The difficulty of finding a generally acceptable substitute for Euclid was fatal to the proposals of the Association for the Improvement of Geometrical Teaching, and the controversy between the supporters and the opponents of Euclid has been a main feature of all discussions concerning the improvement of the teaching of mathematics in this country. Now it may be contended that we ought not to attempt to present geometry to children as a formal system deduced from a minimum number of assumptions; but that our objects should be to impart knowledge of the properties of geometrical figures and to cultivate power of geometrical reasoning. Upon the general adoption of this view of the true objects of geometrical teaching, the above-mentioned difficulty would disappear; for it is safe to assert that these objects can be secured better without Euclid's book than with it. In this matter the French are far ahead of us. Their text-books of geometry have been evolved by a natural process of development from the "Géométrie" of Legendre; and text-books similar to those of France are in use in Germany, Italy and the United States. It is far from my purpose to suggest that British teachers should now adopt as a substitute for Euclid a translation of a French book or any other foreign book. In all these books too much attention, as I think, is paid to the development of a formal logical system, with the result that much space is occupied in proving propositions that are sufficiently obvious without proof. We have yet to work out for ourselves the method that is best suited to our educational needs and national temperament. This cannot be done without freedom from the tyranny of an orthodox standard; nor can it be done in a hurry. Changes will have to be made gradually. In this connexion we may note that the memorial sent by some schoolmasters to the committee of the British Association (NATURE, January 16, 1902, p. 233) points out a promising method of beginning to make changes. If the chief examining bodies would now sanction such a departure from existing practice as is there proposed, progressive reform would become possible.

The contention that Euclid's "Elements" is an unsuitable text-book is borne out by a critical scrutiny. The book was an attempt to deduce a complete system of geometry from a minimum number of assumptions, contained in definitions, axioms and postulates. No such attempt, even if completely successful, can possibly appeal to immature minds; and it is well known that Euclid's attempt, in spite of its many conspicuous merits, is logically defective. This would not matter very much if it were otherwise well adapted to effect the two objects which we have noted above as the true objects to be aimed at in teaching geometry. Notoriously it is not so adapted; striking instances of its deadening effect upon the minds of average boys have been recorded by Prof. Minchin and others. Such instances may fairly be cited in opposition to the claim, urged by the supporters of Euclid, that his system affords valuable mental training; and this claim does not gain in force when it is observed that most of the men who have undergone the training appear to be unable to appreciate the logical defects of the system, and that they accept without question the absurdities that are often made to do duty, in our text-books of analysis and mechanics, as definitions or as proofs. Further, the tacit agreement to drop Euclid's fifth book has robbed his sequence of its significance. This book is really the great contribution of antiquity to the problem of irrational numbers—perhaps the central problem of mathematics. It is certainly the keystone of Euclid's system. Without it, there is no reason why proportion and measurement, treated arithmetically, should not take a much earlier place in a system of geometry. In elementary stages, it will probably be best to postpone all questions of incommensurable magnitudes and irrational numbers; but sooner or later, in the training of a mathematician, such questions must be faced. The Greeks approached arithmetic through geometry, and for two thousand years Euclid's fifth book was the only theory of irrational nnmbers. Now, however, the Greek way is not the only way, nor, as I believe, the most excellent. There exists now a complete arithmetical theory of irrational numbers; and the theory of exact measurement of incommensurable, as well as of commensurable, magnitudes can be founded on a secure arithmetical basis. This revolution of mathematical thought was accomplished in Germany in the second half of the nineteenth century; its full effect has yet to be felt.

But geometry is not the only branch, even of elementary mathematics, of which the aspect would be changed entirely by giving effect to the above-stated principles of reform; nor is the need for improvement confined to the teaching of elementary mathematics. In algebra, for example, the changes advocated in the book under notice, or those proposed in the memorial of some schoolmasters already referred to, would constitute great improvements in the method of presenting the subject. Here again the French text-books are much better than most of ours. In analysis generally, the traditional order of the topics stands in need of drastic alteration—boys and girls ought not to be taught to expand the circular functions in infinite products before they have ever plotted a graph or differentiated the simplest expression. Prof. Perry has been a constant advocate of graphic methods and of the early study of the differential and integral calculus. He holds that this study should precede that of many things which now come before it, *e.g.* advanced analytical geometry of conics; this view is put forward on the ground that such an order would be more helpful to those students who will afterwards require to use mathematics in the practice of their professions. They are not the only students who would gain by the change. The educational value of mathematics would be increased enormously. Mathematics becomes an instrument of liberal education, not merely by the practice of processes—they are means to an end—nor yet by the storing of information, though knowledge of facts is an element of culture—but by the formation of exact ideas as regards both the definiteness of its fundamental notions and the inevitableness of its results. The impression that is made upon the mind, when one realises the inexorable necessity of the conclusion of a chain of reasoning, is the element in mathematical training that has been emphasized the most by those who support the claim of mathematics to be considered an integral part of a liberal education; but it may be held that the illumination to be derived from any of the fundamental notions of mathematics—such notions, for example, as proportion, continuity, vector, group—when they are thoroughly grasped, is a not less important element from the same point of view. The traditional order of study has tended to obscure the fundamental notions and the general drift of the arguments under a cloud of secondary developments. That the differential and integral calculus can be presented at such a stage as that indicated by Prof Perry, in a manner so practical as to suit the student of engineering, and at the same time so rigorous and so luminous as to be a worthy means of liberal education, has been shown by more than one recent treatise. The examinations that have most influence upon the order of study near this stage are probably those for entrance scholarships at the colleges of the older Universities. A few reforming tutors might now initiate a change that would produce a very great effect.

It is unnecessary here to follow out the application of the principles of reform to mechanics, or to the remaining subjects of a school course of mathematics. The book under notice contains numerous suggestions on these heads. Some readers may be inclined to think that in the introductory address, and in some of the subsequent speeches, undue prominence was given to the needs of students who are destined to become engineers, or teachers in primary schools. A view that is held widely, but has not perhaps been emphasized sufficiently, is that, in the stage of ordinary school work, the course that is most suitable for such classes of students is also precisely the best for those for whom mathematics is meant to be a means of culture and for those who have the ability, and will afterwards have opportunities, to assist in the development of mathematical theories. To bring such a course into general use will require much persistent effort, directed continually to one end; and the first step will necessarily be the conversion of examiners and of the bodies that make regulations for the conduct of examinations. The future of mathematical teaching in this country is in their hands.

A. E. H. L.

A STUDY IN FISH MORPHOLOGY.

Pleuronectes. Liverpool Marine Biology Committee's Memoirs on Typical British Marine Plants and Animals. No. viii. By F. J. Cole and Jas. Johnstone, B.Sc. Pp. 252; 11 plates, 5 text figures and a table. (London: Williams and Norgate, 1901.) Price 7s.[1]

OF the now numerous publications of the Liverpool Marine Biology Committee which have appeared since its foundation, none are of greater service to zoologists and students than those of the series to which the volume under review belongs. They are each a detailed study of some individual organism, prepared by a writer or writers specially familiar with the group to which it belongs; and under this guarantee of authority, they are consequently welcome and most useful wherever the zoology of the British seas is studied or taught. The first memoir, on the "Ascidian," by Prof. Herdman (to whom honour is due for having inspired and initiated this most admirable series), appeared but in 1899; and in the interval of little more than two years which has elapsed, there have been published seven others—the present volume being the eighth. In bulk and descriptive detail, this is by far the most extensive and elaborate yet issued, since it is nearly three times the size of its heaviest predecessor, and is illustrated by eleven plates as compared with a previous maximum of seven. When, however, it is remembered that it has two authors and deals with a verteb rate, and that it exhausts not only the orga nology, but treats of the life-history, habits and economic aspects of the fish selected for treatment, it is evident that a just allocation has been given it. Indeed, in its method of treatment it is at once both wider and more special than its predecessors.

Both authors have already so distinguished themselves as trustworthy investigators, at Liverpool and elsewhere, that their cooperation gave promise of a good result, and in the end our highest expectations have been fulfilled.

The introduction to the book opens with a consideration of classification, the value of the Müllerian subordinate term "anacanthini" (now unquestionably doomed) and of the less familiar "heterosomata" being duly explained. In dealing with the external characters, the more recent work on chromatology is adequately incorporated, with due mention of authority; and while the descriptions of the lateral line organs and scales are fully up to date, and the "breathing valves" are duly recognised, slight error is obvious only in the application of the terms descriptive of the condition of the tail to that organ and not the fish itself. The subjects of torsion and asymmetry, as involving the head and dorsal fin and leading up to accurate definitions of the "eyeless" and "ocular" sides, are extremely well handled, both in this introduction and in a subsequent section, following that treating of the eye-muscles, which play so important a part in the processes involved and in furnishing a clue to their real nature. Rival theories are discussed, to the denunciation of those of Cunningham, based upon the study of the sole, certain other of whose observations come in for criticism in many pages of this work.

The osteological chapters come next in order of succession, and they are thoroughly good and sound. The bones of the "eyeless" and "ocular" sides are alternately described; the compound nature of the pterotic and sphenotic elements is fully considered, in its bearings on both morphology and terminology; the absence of the left nasal is explained; and the details in respect to which the inter-maxillary cartilage enables the plaice (in contradistinction to other Pleuronectidæ) to pick up food on its eyeless side, are made admirably clear. The vertebral column and fin-supports are fully considered; and while we doubt the advisability of retaining the term "atlas" for the first vertebra, we welcome the adoption of "axonost" and "baseost" and the recognition of the work of Traquair, Bridge, and others who are named. We regret, however, that while our authors were thus far revising their terminology they did not, for once and for all, replace the term "anal" in ventral for the post-anal median fin.

Concerning the anal spine, it is noteworthy that the authors have been at immense pains to be perfectly sure that this does not project uncovered during life; and it may be said that no less labour has been bestowed upon the accurate determination of the nature and precise limitations of the pancreas, the lymphatic portion of the head-kidney, the thymus gland, and other organs which text-book writers are too apt to sketchily consider. Their desire to be thorough at all costs is, in fact, one of the distinguishing features of their book; and consequently, we find descriptions of the adult supplemented by comparison with the young, as in their account of the development and retrogression of the thymus, of the thyroid and suprarenal organs, of the hypoblastic origin of the "bladder" (which we rejoice to find termed the *urocyst*) and other allied parts. In all this and a great deal more their memoir is a record of laborious research, done for the love of the work and with the determination to be exact; and no less praiseworthy are their literary efforts, which have led them, when called upon to deal with things of doubtful homology or function, to state fully alternative possibilities, with due reference to authority, as, for example, in their treatment of the "interclavicle" and the "pyloric cæca."

The section dealing with the blood vascular system calls for no especial comment, except that it is accurate and well done, and that a good service has been rendered in a *résumé* of the chief conditions assumed by the pseudobranchial vessels. The authors' extreme caution is again obvious, in their refusal to decide upon the homology of this pseudobranch (in the absence of a related afferent branch of the ventral aorta) until dealing with its inn rvation. And this leads naturally to the consideration of their section on the nervous system, which, as might be expected from the senior author's work, is their *pièce de résistance*. In the portion of this which deals with the cranial nerves, we are taken at once into a dissertation on the two-root law of Bell and the four-root theory of Gaskell; and, apropos of the far-reaching investigations of Strong and the labours of Herrick on Menidia, to a classification, based on the "component theory" and work done under the conviction that the whole course of these

[1] Like three of its predecessors, which were written wholly or in part by members of the staff of the Lancashire Sea Fisheries Laboratory, the memoir is also incorporated as an Appendix in their Annual Report Rep. x. 1901).

nerves should be determined by means of serial sections. Rather too much this to expect from the ordinary student! especially when it is seen that the classification discriminates between five systems (viz.—somatic-afferent and -efferent, viscero-afferent and -efferent, and acustico-lateral) "each delimited by a uniformity of peripheral termination and a special characteristic origin in the brain," and each liable to "appear in a variable number of cranial nerves as a component of those nerves." Our authors tell us they have adopted this method for the plaice, and in proceeding to the systematic description of its cranial nerves they deal with them in order of functional association. The olfactory, optic and eye-muscle nerves are first considered; then the fifth and seventh; after the study of their root-ganglia, the eighth, ninth and tenth, completing the series. With the spinal nerves, the fourth is described first, and the first three later in order of succession, because they are less typical and by virtue of their especial relationships to the pectoral member. It is impossible here to go more fully into the details of this very technical subject; suffice it to say that all is most admirably set forth, and that while a really good description of the sympathetic system is given which may serve as a model to writers of the future, both the giant cells of the cord and the most recently revived Reissner's fibre are described and discussed with full bibliographic treatment. Special discussion is given to the question of the innervation of the pelvic member, in its bearings on translocation and nervous substitution, as a guide to homology. The authors' arguments under this head have an especial interest, in the recent announcement by Dr. A. Smith Woodward of the startling discovery that, in Cretaceous times, teleostei of the clupeoid type had already translocated the pelvic fin into the jugular position.

Following this are sections dealing with the sense organs. Kyle's discovery of a pleuronectid with a naso-pharyngeal aperture and Holt's "recessus orbitalis" meet with due recognition, and here again all is admirable and fully up to date. The aforementioned thesis on asymmetry is conveniently introduced at this point, and there follow sections on the ear and reproductive organs, with a *résumé* of the present state of our knowledge concerning the sexual organs of the female teleosteans in general, in which Huxley's terminology is employed.

The book closes with an appendix, containing valuable information on spawning and the spawning season, on the maturation and structure of the egg, on oviposition, fertilisation, development and metamorphosis. Rate of growth, the nature and causes of migration and distribution, are duly dealt with, and there follows a brief sketch of the plaice fishery in northern European waters, with some sound advice to the practical fisherman. In not a few pages in the book there are hints as to the work of the future, as, for example, at the very outset, where there are described a sporozoon and a myxosporidian yet to be determined.

Of the eleven plates, all are admirably clear, and figures useful as are those of the cranial nerves, the olfactory sacs and the sympathetic system are most welcome. It is well known that in the production of this series of memoirs the cost of illustration has been largely defrayed by private donation. In the present case the publication committee of the Victoria University have performed this graceful task, and we congratulate its members upon their bargain. A better treatise on a single animal form there hardly exists, and while we would tender to editor, authors and all interested or concerned our heartiest thanks, we cannot refrain from an expression of national pride, in the extent to which it is evident from the pages of this work that the science of comparative ichthyology is essentially English. The book reflects the influence of the schools in which its authors were trained, and is a credit to them and to science in Britain. Our only fear concerning it is that it will be found too voluminous for the mere student, of whom so much is expected in so short a time. There is a danger that at first glance he would be repelled by the great amount of detail, and that thereby the subject of zoology might suffer. Selection can, however, always be arranged under a competent teacher, and for those desirous of specialising in ichthyology we could recommend nothing better. The book is healthy in the extreme, and while it will educate the student on sound lines, it will arouse in him the desire for reinvestigation and research, no opportunity of directing attention to which has been lost.

THE GOLD OF OPHIR.

The Gold of Ophir: Whence Brought and by Whom? By A. H. Keane. Pp. xviii + 244. With one plate and one map. (London: Stanford, 1901.) Price 5*s*. net.

IN the little volume before us Prof. A. H. Keane has undertaken an inquiry into the vexed question of the site of Ophir, and the source of the gold which the Hebrew Scriptures assure us was brought from that place to Solomon, son of David, by ships of Tarshish. The author himself feels that some apology to the reader is necessary, and that some explanation is due to him for having taken up the subject at all, and it is our duty to say at the outset that we wish he had left it for discussion to the class of people who triumphantly assert that Rhodesia is Ophir, and that Britons inherit this colony (which was founded by masterful Mr. Rhodes) as their natural right because they are descendants of some of the tribes of Israel. Prof. Keane thinks that so much evidence has accumulated on the subject during the last thirty years that it is time the question was reopened, and not only reopened, but decided once and for all. The evidence he refers to consists of the results obtained from the exploration and study of Rhodesian remains, from the Himyaritic inscriptions found in central and southern Arabia by Glaser and others, and from the explorations of the "Arabian frankincenseland" by the late Mr. Bent, and from parallels between the social and religious customs of the Malagasy inhabitants of Madagascar and "their Himyaritic, Phœnician and Jewish masters from the northern hemisphere." Incidentally we may mention that Dr. Carl Peters, in 1901, enunciated the extraordinary view that, not only was the site of the Ophir of the Bible to be found in Rhodesia, but that Ophir was to be identified with the Punt of the Egyptian inscriptions.

Prof. Keane has devoted several chapters of his little

book to attempting to prove his theories by appeals to facts philological and geographical; but all that can be said for his arguments is that if every assumption is correct, the deductions which he makes may be true, but if almost any one of them breaks down, his whole fabric must collapse. For example, Prof. Keane says unhesitatingly,

"the original Punt was South Arabia (Arabia Felix, Yemen), whence the name was extended to Somaliland during the eighteenth dynasty, say, about 1700 B.C."

But this is impossible, for in the sixth dynasty Punt was in Africa, and was probably reached by way of the Nile; and as the inscription of Her-khuf, formerly at Aswân and now at Cairo, contains the oldest mention of Punt in such a way that its position can be traced, we see at once that, so far as this remote period is concerned, Prof. Keane has no satisfactory authority for his statement, "the original Punt was South Arabia." The Punt of the eighteenth dynasty was reached in exactly the same way as it was reached in the reign of Seānkhka Rā (eleventh dynasty), and all the Egyptological evidence available goes to show that the region visited by the Egyptians at both periods was in Africa.

Prof. Keane thinks little of the evidence which Dr. Peters has deduced from the "*ushabte* figure impressed in a mould" which he found in the middle of Africa during his last expedition, yet he accepts the description given of it to the effect that it has "in each hand a scourge instead of a hoe." If the figure is an *ushabti* figure, and was really made in ancient days in a region far to the south of Egypt "for a courtier of Thothmes III.," the objects in the hands must have been intended to represent the flail and the hoe of Osiris, otherwise the whole figure is meaningless. In any case, how can it have a curious significance (p. 35) because "it is armed with a scourge in each hand, and [was] picked up in a mining district"? Let us hope that this wonderful figure may be placed somewhere so that it may be inspected by those interested in the matter.

Prof. Keane relies too much upon the statements of the late Mr. Bent in the deductions which he makes about the ruins at Zimbabwe, and this is the case also in respect of the views of the Hon. A. Wilmot, who wrote a volume entitled "Monomotapa," and who adopted nearly all Mr. Bent's views. Mr. Bent was an intrepid traveller and an accomplished gentleman, but he knew no Semitic language and his training as an archæologist was rather classical than anything else; his opinion on all Phœnician matters was, therefore, that of an intelligent but untrained amateur.

Our want of space prevents the possibility of discussing many of Prof. Keane's philological dicta, and we must pass on to his

"important conclusions," which he trusts "may now be considered fairly well established, and may therefore legitimately take the place of the many theories and speculations hitherto current regarding the 'Gold of Ophir,' its source and forwarders" (p. 194).

These are:—Ophir, on the south coast of Arabia, *i.e.* Moscha, or Porters Nobilis, was the distributing market of the gold of Havilah, or Rhodesia. The mines of Rhodesia were first worked by South Arabian Himyarites, who were followed in the time of Solomon by the Jews and Phœnicians, and these very much later by the Moslem Arabs and Christian Portuguese. Tarshish was the outlet for the precious metals, and was near the modern Sofala. The Himyarites and the Phœnicians reached Havilah through Madagascar, where they maintained commercial and social intercourse with the Malagasy natives. With them were associated the Jews, by whom the fleets of Hiram and Solomon were partly manned. There is, of course, something to be said for all these views, because each represents a possibility, but the facts required to prove them are wanting. Nevertheless, Prof. Keane's book is as valuable as it is interesting, because it has put the question on a scientific base, and we are glad to see that he has freed himself from the ordinary traditional trammels in dealing with it. Moreover, we must acquit him of all mercenary motives in trying to prove that the gold which Hiram and Solomon's fleets obtained from Ophir came from Rhodesia, for so far as we know, he has no pecuniary interest in the mining operations which have been carried on in that wonderful country during recent years. The "notes" which he gives will be very useful to other workers in the same field, and his index facilitates the profitable perusal of the present book.

EXPERIMENTAL WORK WITH GASES.

The Experimental Study of Gases. By Morris W. Travers, D.Sc. With preface by Prof. W. Ramsay, D.Sc., F.R.S. Pp. xii + 323. (London: Macmillan and Co., Ltd., 1901.) Price 10*s.* net.

IN 1857, Robert Bunsen published the first edition of his classical work "Gasometrische Methoden," and twenty years later a rewritten and enlarged edition of the same, which still ranks as a standard text-book on the subject. We think it is not too much to say that since that date no more important work has been published on the properties of gases in general than the one now before us. The progress made in our knowledge of the subject has probably been at least as rapid as in any other department of chemistry, and the discovery within the last half-dozen years of five new elementary gases, in the investigation of the properties of which Dr. Travers has taken a prominent part, would alone afford justification for this volume, did it contain nothing else of merit.

The volume consists of 320 pages, with numerous illustrations, most of which appear to be original and not merely reproductions from current text-books. The first portion of the book is taken up with a detailed description of the apparatus used, and the methods employed in the preparation of gases in a state of purity and their accurate measurement and analysis. Then follow chapters on the gases of the helium group, the determination of density and the relations of pressure, temperature and volume, the liquefaction of gases, and finally their properties and the constants relating to them. Careful perusal of the work leads us to the impression that in this case (as is by no means always the rule) the best chapters are those on the subjects with which the

author is peculiarly at home, namely the sections dealing with the gases of the helium group and with liquefaction. On the other hand, the chapter on the preparation of pure gases is somewhat disappointing, not so much on account of what is said as because of what is left unsaid.

In the introductory fifty pages we notice much valuable information, obviously the outcome of experience, regarding the construction of apparatus, such as Toepler and Sprengel pumps, and practical hints on such matters as the cleaning by means of zinc dust and hydrochloric acid of glass apparatus which has become dirty by long-continued use with mercury.

While referring to pumps, we may mention that the statement on p. 15 that a filter pump with a good head of water will reduce the pressure in a vessel to the vapour-pressure of water at the time is well inside the mark. In the writer's experience it is not uncommon to obtain by selection a filter pump which will reduce the pressure to much more nearly one millimetre than 15 to 20 mm., the latter being a degree of vacuum quite easily attainable with almost any good pump and moderate pressure.

For flexible connections to stand high pressures or vacua, the thin weldless steel tubes recommended by Dr. Travers should always be protected by an outer sheath consisting of a compo tube slipped over the steel and drawn tight on to it through several holes of a draw plate. This prevents the steel suffering, as it is very liable to do, from too sudden bends or from accidental crushing.

In attempting to preserve for long periods gases collected in a sample tube over mercury, great caution is needed in seeing that the surfaces of the tube are quite clean and free from grease, and that the mouth dips well under the mercury in the vessel in which it is placed. Otherwise slow inward diffusion of air may occur along the walls.

In the chapter on the preparation of pure gases we should have liked fuller descriptions of the methods, and more of them, the details in some cases being decidedly meagre and several of the methods recommended being only suitable for the preparation of very small quantities of gas.

The electrolytic preparation of hydrogen and oxygen from dilute sulphuric acid is a method which does not receive the author's commendation for ordinary use, but most of the disadvantages disappear, at least in the preparation of oxygen, if phosphoric acid is taken in the place of sulphuric.

No mention is made of the electrolysis of hydrochloric acid and the preparation of the intensely interesting mixture of chlorine and hydrogen sensitive to light, although this experiment is attended with peculiar difficulties.

On p. 74, reference is made to the "Paris kilogram," an ambiguous and unnecessary term if the now almost universally recognised international kilogram is meant (let us be thankful that there are not as many kilograms as ohms), and on p. 130 we find the statement,

"The results (weighings of gases) are reduced to the values which would have been obtained at sea-level in latitude 45°. They may be reduced to the Paris standard by multiplying by 1·000316."

We fail to see why, after having reached lat. 45° and sea-level, some charm in the local value of gravity should induce us to come back and reweigh the gas at Paris. It may be mentioned here that the very divergent values quoted on p. 74 for the mass of a cubic decimetre of water at 4° ought to be replaced by more modern data, which agree in fixing $999·95 \pm ·02$ grm. as a much more probable value.

We are glad to see that in the chapter on gas analysis Dr. Travers has weeded out from the many forms of apparatus and methods employed those only suitable for *technical* use, describing only those capable of scientific accuracy, with copious references to the most recent work on the subject. The usefulness of the chapter would, however, have been increased had a description been given of some form of complete apparatus for general gas analysis, such as that of Prof. MacLeod, or one of its later modifications.

We may sum up the chapter on the preparation and properties of the gases of the helium group by saying that it contains practically all that is known on the subject.

Temperature measurement by the gas thermometer is gone into at considerable length; and the convenient and accurate compensated constant-pressure thermometer of Prof. Callendar is illustrated and its working described in detail.

In the chapter on the liquefaction of gases, a full account is given of Dr. Travers' own experiments on the liquefaction of hydrogen, which is a reprint, with additions, of his recent paper in the *Phil. Mag.* This concludes with an account of the cost of these experiments, in which it is stated that, after an outlay of about 250*l.* on the complete plant, an expenditure of about 1*l.* each time covers the cost of making liquid hydrogen.

Anyone familiar with some of the palatial laboratories of many of the physical chemists abroad, visiting for the first time the dingy dwelling of the chemical department at University College, which the school of Ramsay has now made classic ground, could not fail to be surprised at being shown the hydrogen liquefier fitted up in a disused lavatory, and to hope that in the coming London University scheme physical chemistry may find a worthier home.

To return to the book, it appears to be accurately printed, and although we have verified many of the numbers and constants given, the errors we have detected are not numerous.

Among the slips may be pointed out, Kaysir for Kayser; Wülmer for Wüllner; Kirschoff for Kirchoff. Fig. 102, which is repeatedly referred to, appears to be missing.

We may conclude by stating how much a study of the book has emphasised in our own mind the importance of Prof. Ramsay's concluding sentence in the preface he has written directing attention to the lacunæ still remaining in many branches of our knowledge, and by heartily congratulating Dr. Travers on his labours, which have produced a book worthy of a place in the reference library of every student of modern chemistry. J. A. H.

OUR BOOK SHELF.

Tafeln zur Theoretischen Astronomie. By Julius Bauschinger. Pp. 148. (Leipzig: Wilhelm Engelmann, 1901.) Price 12*s*. net.

MOST astronomers are familiar with the very excellent volume entitled "Formeln und Hülfstafeln für Geographische Ortsbestimmungen," by Prof. Th. Albrecht; this work contains in a small compass most of the formulæ and tables required for geodetic work, and the very clear descriptions of the processes involved make the volume a veritable *vade mecum* for those employed on such work.

The volume before us does for "theoretical astronomy," that is astronomy dealing with the determination of the positions and orbits of bodies in space, what the above-mentioned book does for geodetic work, and the main attempt of the compiler has been to bring together in a compact and complete form all that is required by the computer, rendering it unnecessary for him to seek aid from other books. In this class of work the computer has generally to consult more than one volume in which suitable tables for his calculations occur, such as, for instance, the valuable work of von Oppolzer, and in some cases the tables are not of the most convenient form.

The present volume, therefore, serves a most useful purpose, and the arrangement of the tables leaves, so far as can be seen without actually working out a problem, little to be further desired. The tables, which are forty-five in number, are arranged under six sub-heads. The first of these divisions is devoted to such objects as conversion of time into divisions of arc, mean time into sidereal time, &c., and *vice versâ*. The next is for the determination of the true anomaly from the time and *vice versâ*, for elliptic, parabolic and hyperbolic motion, and here three methods for the solution of Kepler's equation are given; two of them are based on Tietzen's solution and are purely computational, while the third is after the graphical method of Waterston and Dubois and is accompanied by two loose charts.

The third set of tables deals with the part of the problem relating to the determination of the first approximate orbit, in which both Euler's and Lambert's equations are required; while this is followed by tables which serve for the computation of special perturbations and improvement of the elements determined by the first approximation.

The fifth part gives the means for calculating precession, nutation, aberration and parallax, and contains a list of the chief observatories of the world and their coordinates, with data for parallax determination.

The sixth and last section is formed of miscellaneous tables which are of general use in work of this kind; thus we have formulæ and tables for interpolation, differentiation and integration, mechanical differentiation, &c., concluding, amongst others, with mathematical, astronomical and geodetic constants.

All the tables which depend on astronomical constants have been recalculated and based on the Paris Conference constants, while each table is clearly explained and in most cases accompanied by an example worked out step by step.

This book of tables will, with very little doubt, be of considerable service both to the experienced computer and to the student who is working out orbits for the first time. Great praise is due to the compiler who has performed this laborious task with so much care and with such success.

An Elementary Treatise on Alternating Currents. By W. G. Rhodes, M.Sc. (Vict.). Pp. xii+211. (London: Longmans, Green and Co., 1902.) Price 7*s*. 6*d*. net.

MR. RHODES' treatise on alternating currents can hardly be regarded as particularly elementary, since he certainly assumes in his readers a preliminary acquaintance with the principles of the subject. We are inclined to think that although the mathematical parts are good, the treatment on the electrical side, especially in the simpler parts, leaves a good deal to be desired. Thus on p. 23 the quantity $2\pi n\mathrm{L}$ is defined as the reactance, whereas a few pages further on (p. 31) this name is used for the fuller expression including self-induction and capacity, without any explanation as to why the same term is used in both cases; the same observations apply to the definition of impedance. One may be pardoned for laying stress on such faults as these, since the subject is at best a difficult one, and without a perfectly sound knowledge of the fundamental ideas, the student will never make much progress.

The author has aimed at using the calculus as little as possible, and, where its employment is inevitable, has given the solution of an equation in the text and the working in the appendix. Many of the problems are solved by vector algebra, to an explanation of the principles of which a short chapter is devoted. The design of transformers and the theory of the synchronous motor and polyphase currents are treated at some length. It is to be noted that although hysteresis is of necessity considered, it is nowhere adequately explained. Another omission is that no description is given of any method of determining the wave form of an alternating current or P.D., although there is a chapter on the subject of alternating measurements. We do not doubt that the book will be found very useful, but its value would be greatly increased by a more careful attention to thoroughness and completeness. M. S.

Cyanide Practice. By Alfred James, Member of the Institution of Mining and Metallurgy, F.G.S., F.C.S. Pp. xii + 174. (London: E. and F. N. Spon, Ltd.; New York: Engineering and Mining Journal Incorporated. Not dated). Price 15*s*. net.

ALTHOUGH there are now a number of books in which some information on the cyanide process can be found, a full and satisfactory description of it has not yet been written, and can hardly be expected until more experience has been gained. Meanwhile, no instalment of the complete account can be more interesting and important than that giving a record of the experience and views of Mr. Alfred James.

Mr. James was the pioneer of the process in South Africa in 1888, and to him belongs the credit of adapting it to the treatment of auriferous tailings at a time when cyanide was in some danger of being set aside for the time owing to the difficulties encountered in the treatment of virgin ores with its aid. When a good start had been made, and the value of cyanide solutions demonstrated, a host of workers took up the task and a vast industry was created on the foundations laid by Mr. James; but the part he played in promoting the prosperity of the Witwatersrand gold mines will always be remembered with gratitude by metallurgists.

As might be expected, the book is full of good things, details of construction of vats and extractor boxes useful to the general manager, hints on extraction and precipitation designed to aid the millman, and hitherto unpublished researches on bromocyanide which will be read with avidity by the chemist. The method of arrangement, however, leaves something to be desired. Some sections consist of papers read at various institutions which have been reprinted almost without change and without much effort to make them part of a coherent whole. The imperfections of the index render it difficult to refer to any particular point, and the only way to avoid missing important details is to make oneself familiar with the whole book, which is, fortunately, tersely written and by no means long. Difficult as it may be, however, to take full advantage of Mr. James's work, no one concerned in the cyanide process can afford to do without the volume which he has produced.

Index Kewensis Plantarum Phanerogarum. Supplementum primum. By Theophilus Durand et B. Daydon Jackson. Pp. 120. (Brussels).

ON the title-page of this, the first supplement to the "Index Kewensis," the name of Monsieur T. Durand, the director of the botanical garden at Brussels, is associated with that of Mr. Daydon Jackson, the author of the original work. Mr. Durand is mainly responsible for the new part, which deals with species and varieties which have been named during the decade 1886–1895. In order to maintain uniformity, the same arrangement is adopted as in the "Index Kewensis." Most of the new plants are tropical, and quite an appreciable addition is due entirely to Kuntze, who has upset several of the ordinarily accepted genera, though for the most part species names are unchanged. This part takes the genera as far as Cymbidium.

It is hardly necessary to point out the importance of keeping a standard work of this kind up to date, and the author has rendered a great service to systematic botanists in bringing out so quickly, considering the great labour involved, this additional record of plant names.

The Misuse of Coal.

As England has taught the world how to use coal, she ought to think of teaching the world how to use coal without waste. Coal is so plentiful, so cheap; it is so much to the interest of many people that the waste should go on, and the general public, who alone can apply a remedy, are so ignorant of natural science that when, every few years, I draw attention to this subject, I feel my efforts to be hopeless. Nevertheless, you will perhaps allow me to call attention to the fact that in the very best and largest steam-engines less than 10 per cent. of the energy of coal is utilised; in many small engines only 1 per cent. The remaining energy is quite wasted.

In the electric generating station of a city like Manchester, there are engines of 12,000 horse-power, driving tram-cars and house-lights. In a line of battle ship there is more than twice this power. Two new Cunard steamers are, I understand, about to be ordered, each of which will have 48,000 horse-power. The great waste of energy inevitable in all heat engines of the world is therefore enormous.

It is known that when fuel energy is converted into the electric form directly, as in a voltaic cell, more than 90 per cent. of the fuel energy is convertible into the mechanical form, but at present contrivances to do this even in the case of gaseous fuel are too bulky and expensive to compete with heat engines. I wish once more to suggest that an organised attempt be made to convert the energy of coal into electric energy in some form of engine which shall not cost more or have greater weight than a steam-engine of the same power.

For the heating of buildings, Lord Kelvin pointed out long ago that the very law of thermodynamics which makes a heat-power engine inefficient makes it possible to obtain from one unit of energy the effect of 50 or 100 units by direct heating. I know of nothing which so well illustrates the scriptural promise of the seventy and seven fold reward of virtue as this. Discover the energy engine and you multiply your power to heat buildings from coal, seventy and seven times. But how can we make facts of this kind obvious to ordinary men—the men who are said to be educated when they know absolutely nothing of physical science? Even with coal as cheap as it is we might appeal to its selfish users by pointing out that with the new kind of engine a ship would be able to travel ten times as far at full speed as she now can do without coaling.

The world's yearly output of coal recently was 663 million tons. Of this Britain's share was 30½ per cent. If the whole of the energy of Britain's coal for one year could be utilised and charged for at 8*d*. per Board of Trade unit, the price paid in many towns by consumers of electric energy, it would amount to 100 times our national debt. It is to be remembered that the cost of human labour when used most economically is nine times the figure here given.

Here is another fact. Scientific men know of no other store of energy available for man's use than fuel from the earth, except what we may get by the help of the tides or by wind or waterfalls. To depend upon the future discovery of some great store is to act like a spendthrift who knows of no relation whose death will give him more money and yet who goes on wasting his substance. The energy of coal is the foundation of such widespread comfort as we now observe all over the world. To put the matter in a very definite form we may say:—the cost of one Board of Trade unit of energy by the agency of human labour working most economically is seventy pence; the cost of the unit as given out by a large steam-engine in a cotton factory is one farthing; the cost per unit of the coal alone (at 8*s*. per ton) if all its energy were utilised is one one-hundredth of a penny. But when our coal supply is exhausted, when all the races of the world have fought for the waterfalls and places of high tide, the price must go back to the higher figure. The failure of our coal supply is one of the two things neglected by Mr. Wells in his "Anticipations," the recollection of which would have modified all his conclusions. When coal becomes scarce, people will wonder how it was possible for the nations to spend so much money as they all now do, and our grasshopper weight of a national debt will seem to be an unbelievable burden. Seventy pence to a farthing is the ratio of values without and with coal even now, and the ratio ought to be ten times as great, or 2800 to 1.

In sixty years we have greatly destroyed that store of energy which is the foundation of what some of us call civilisation. In another hundred years the English hamlets of contented working folk that have become cities of luxurious people will decay again into hamlets, inhabited by a discontented, poverty-stricken population which will curse its ancestors for their prodigality. They will not curse us for using coal perhaps, but they will know how to economise coal, and so they will curse us for our ignorance. Over and over again have I called attention to the fact that we are wasting the energy-capital of all the inhabitants of the earth for all time to come. The value of human labour gives the normal value of energy, and at this rate we in England are wasting 900 times the amount of our national debt every year. I have dragged this matter into my lectures and papers with and without relevancy many times, and every one of my hearers and readers neglects its significance. Scientific men know it, but they think it useless to try to impress the ordinary citizen, so ignorant of natural science as he is and so unheeding of any kind of danger which was unknown to his forefathers. What annoys me particularly is not so much the selling of my birthright as that I should sell it for such a mere mess of pottage.

To return to my cry for a new invention. Many men have advanced the subject beyond its first principles; they know of directions in which to work with prospects of success. In the animal machine the thing is actually done; but of this machine

the mere conversion of fuel energy into mechanical work is not the most important function, and the machine is very complex. Still, in it we have no heat engine, but the sort of thing we are looking for. I do not wish to set capitalists and patent lawyers against me, and so I will not give my reasons for saying that there is no sufficient temptation for any scientific man to take up the quest. Unless it is taken up as a matter generally recognised to be of national or world-wide importance, there is no more use in tackling the problem than in hunting De Wet with a small army. Many scientific men must combine their efforts in an organised way, freely communicating their ideas to one another and consulting each other as to their experiments. They must be made free from pecuniary cares and assured of great rewards in case of success. I feel sure that if one or two chiefs like Lord Kelvin or Lord Rayleigh were entrusted with the expenditure of a million a year for two or three years by the English nation for the benefit of the world, with power to impress the services of all scientific workers likely to be of use, to make their operations as extended as they pleased, they would bring the invention within reach of the ordinary engineer.

JOHN PERRY.

Birds attacking Butterflies and Moths.

IT was inevitable that the question of birds attacking butterflies would lead to some account of their attacks upon moths. Although I do not believe that any doubt has been thrown upon the keenness and frequency of the pursuit of moths by birds, a few examples of unusual interest deserve permanent record.

About the year 1887 I saw a fine specimen of the Lobster Moth (*Stauropus fagi*) at rest on the lamp-post at the entrance to Norham Gardens, Oxford. So far as I was aware, it was the first specimen which had been noticed in Oxford, and I was anxious to secure it. The moth was gently touched by a stick tied to an umbrella and came fluttering down feebly towards the ground, when, as I ran to catch it, a sparrow dashed across and seized it before it had reached the ground. I chased the sparrow, encumbered with the heavy moth, for some distance, and at first thought it would relinquish the prize. But it soon flew up to the roof of a house and ate the moth in the rain-water gutter.

I am indebted for the second and very remarkable example to Mr. W. Eagle Clarke, of the Edinburgh Museum of Science and Art. He writes, March 1:—"I send you an account of what I think is a somewhat unusual instance.

"In June last, as I was walking at midday along the road which runs close to the shore of Loch Assynt, in north-west Sutherland, a male Oak Eggar Moth (*L. quercus*) dashed past me with the swift irregular flight characteristic of that species. Suddenly a wheatear, a male, gave chase and, after several failures at capture, succeeded, after a clever but trying pursuit, in securing its prey. The body, &c., of the moth was eaten on the road, where I found the wings, the only remains.

"If I had not seen this 'flight' from start to finish, I should not have thought it possible that a wheatear could have been so swift and smart on the wing, for, as you know, an Oak Eggar is not an easy quarry to secure when in flight.

"I have seen a great titmouse capture the white butterfly—*Pieris rapae*—on the wing."

I am sure that any naturalist who is familiar with the flight of the male Oak Eggar will feel all the astonishment which Mr. Clarke expresses at the success of the bird.

The two remaining examples deal with attacks upon the pupæ of moths.

In July, 1900, Mr. A. H. Hamm, of the Hope Department, showed me a number of cocoons of the Lackey Moth (*C. Neustria*), which had just been opened, probably by sparrows, and the pupæ extracted.

The cocoon is tolerably dense, and is probably still further protected by an abundant sulphur-coloured powder which consists of minute crystals of aragonite (calcium carbonate), secreted by the malpighian tubercles of the larva and extruded from the anus before pupation. The cocoons were spun upon the under sides of leaves of black currant and apple, and it was of the highest interest to observe that every one had been opened by the bird pecking a hole in the leaf from the upper side and thus making an aperture in by far the thinnest part of the cocoon. The observation was made in Mr. Hamm's garden in St. Mary's Road, Cowley Road, Oxford.

The last example is equally interesting, but does not deal with the attacks of birds.

Colonel J. W. Yerbury informs me that when collecting on Beown Mountain, Macgillicuddy Reeks, Kerry, on July 21–22, 1901, he found under a stone, at the height of more than 2000 feet, the old winter store of a mouse or possibly a shrew, consisting of eight to ten cocoons of the Emperor Moth (*Saturnia carpini*). Every cocoon had been gnawed through at the base, viz. the end opposite to that from which the moth emerges, and the pupa extracted.

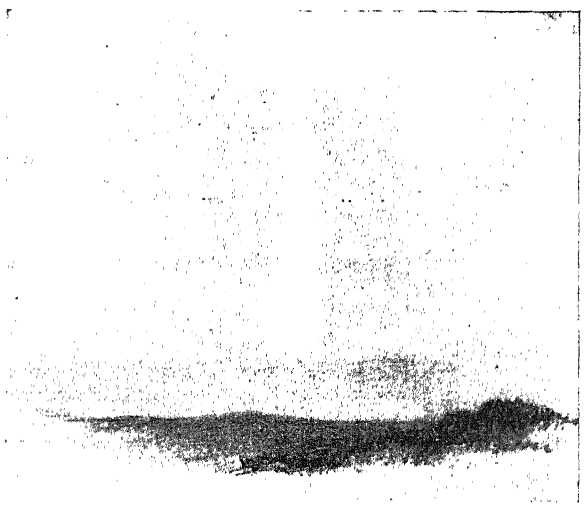
EDWARD B. POULTON.

Oxford, March 6.

Sun Pillars.

ON Thursday the 6th inst. a very fine display of this phenomenon was observed over a considerable area in the west of England, and having regard to Prof. Herschel's interesting letter on the same subject published in NATURE on July 4 last (No. 1653, vol. lxiv. p. 232), perhaps the few facts I have been able to collect may be of interest to some of your readers.

For several days the weather had been exceedingly fine and dry, with hot sunshine and a wind following the sun. The wind on the evening in question had almost died away at sunset; the latter was at 5h. 46m. Greenwich time, and would be about 6h. 5m. here. Close upon 5h. 30m. the light-beam first appeared rising vertically from the sun, which was still visible above a violet-coloured bank of haze; its base did not extend below the sun.



The beam had the appearance of a tall column of very beautiful orange-coloured light brighter in the centre than at the edges; its top must have been quite 20° above the horizon. The sun sank into the haze about 5h. 45m.; the column remained just as bright though reddening gradually until 6h. 20m., and was still distinctly visible at 6h. 40m. It had faded away by 6h. 50m. Faint bands of cloud were visible round the sun, and these sloped from the top of the light-column obliquely downwards in a northerly direction; I also noticed a repetition of the beam on either side of it, though this may have been purely an optical illusion.

I have ascertained that the effect was seen over the whole of Cornwall and Devon, as far east as Salisbury and Taunton, and north as far as Pendine in Carmarthen Bay. Snow has not fallen here for several weeks.

W. H. GRAHAM.

Fowey, March 11.

IN reply to Mr. Knight's inquiry in last week's NATURE (p. 439), he may be referred to many old books, as, for instance, to Moigno's "Répertoire d'Optique Moderne," published in 1847, in the first volume of which he will find a whole section devoted to meteorological optics. The explanation of most of

the phenomena of meteorological optics had, I believe, been worked out by Babinet about ten years earlier.

As to the vertical pillar of light frequently observed in high latitudes after sunset and before sunrise, and occasionally seen in latitudes as low as ours, it may be attributed to spiculæ of ice which, whether isolated or radiating from a centre as in crystals of snow, will assume a horizontal position if they subside through a portion of the atmosphere which is quite free from convection currents. Those of the horizontal spiculæ which are vertically over the cone connecting the spectator's eye and the sun will include some that can directly reflect solar light to his eye, and it is these that produce the phenomenon which was seen by Mr. Knight. The pillar may be expected to be white till the sun gets some distance below the horizon, when it will in succession assume the colours due to the absorption and dispersion of light by the atmosphere.

It can easily be shown experimentally that if the air be free from the minute convection currents which so trouble astronomers (which it seldom is), then subsiding spiculæ of ice will be horizontal. To show this, cut from a sheet of stiff paper a straight, long and narrow strip, and let it fall through the air. The experiment is a pretty one when the strip of paper is thrown out of an upper window on a calm day. The strip falls not lengthwise, but sideways, and spins round its long horizontal axis. The dynamics of this phenomenon have not, I think, as yet been worked out. The explanation would require an investigation of the stream lines surrounding a body rotating as well as progressing through a fluid. It seems to be a problem which might with advantage be proposed to the mathematical research scholars of our Universities.

30 Ledbury Road, W., March 16. G. JOHNSTONE STONEY.

Proofs of Euclid I. 5.

BESIDES the proofs cited by Prof. Bryan (p. 438), another is equally worthy of notice, and requires no construction. The sides of the triangle ABC may be regarded as taken in two orders—

$$\begin{aligned} &\text{AB, AC and } \angle A \\ = &\text{AC, AB and } \angle A \\ \therefore &\angle \text{ opp. AB} = \angle \text{ opp. AC.} \end{aligned}$$

This is a variation of the proof by duplication, but avoids this process. As in the case of the proof cited by Prof. Bryan and involving limiting values, the proof given above is not altogether satisfactory for the use of beginners, and is, of course, of no value to the advancing student except as an interesting illustration of method. H. W. CROOME SMITH.

Bristol, March 15.

As Prof. Bryan is discussing proofs of Euclid's I. 5, may I call attention to the way I proved it in my "Foundations of Geometry," namely as a corollary to the equivalent of I. 4? Thus—

"For if AB in the above proof had been equal to AC, the triangle ABC might also have been moved so that AB fell on DF, and AC on DE, and the triangles would have been congruent so. Hence both the angles ABC and ACB would be shown to be equal to DEF, and therefore to each other."

This seems to me far and away simpler than any other proof I know of, and it has the advantage of directing attention to the fact that the proof of I. 4 as often as not involves turning the triangle over in the air, while moving it; so that, for example, the proof would not apply as it stands to spherical triangles. EDWARD T. DIXON.

Racketts, Hythe, Hants, March 16.

THE NATIONAL PHYSICAL LABORATORY.

SOME further account of the National Physical Laboratory, which is being opened by H.R.H. the Prince of Wales, accompanied by H.R.H. the Princess, as these lines go to press, may be of interest to readers of NATURE. A description of Bushy House, with plans, has already appeared; the alterations required to fit it or a laboratory are now complete, and the new buildings erected for the engineering department are ready or use. The following extracts from the report of the executive committee will indicate what has been done:—

The basement and ground floor of Bushy House have been transformed into a physical laboratory, while the upper floors form offices and a residence for the director. The basement is covered with a brick groining, on which the main building rests, but the more important laboratories are in four large wings, one at each corner, and these have no basement below, thus steady supports are everywhere possible.

One wing, containing the original dining-room and library, has been fitted as an electrical and magnetic laboratory. All iron has been, as far as possible, removed from the structure, and, with a view of preventing a stray magnetic field from any currents which may be used, concentric wiring has been employed for all large currents, while the wires for smaller currents have been twisted.

In this room will be placed the Lorenz apparatus which the Drapers' Company has recently with great generosity given to the Laboratory in memory of the distinguished services to science and to education of the late Principal J. V. Jones, F.R.S., of Cardiff. Along with this there will be other apparatus for the absolute measurement of current and of electromotive force.

Another wing has been fitted for thermometric work. A special study will be made of high-temperature thermometers, and the laboratory owes to the generosity of Sir A. Noble the means for installing a number of electric ovens for testing thermopiles and other instruments for the measurement of temperature up to 1000° or 1200° Centigrade.

In a third wing a metallurgical laboratory has been fitted in which to continue the work begun at the Mint by Sir William Roberts-Austen and the Alloys Research Committee. For this purpose apparatus for cutting and polishing sections and further photomicrographical examination has been obtained. The committee has to thank Mr. Stead for his assistance in arranging this. The fourth wing is fitted as a chemical laboratory. In the basement are a number of constant temperature rooms.

Sir Andrew Noble's fund, referred to in the last report, has provided a measuring machine, a dividing engine and a comparator, which will be placed in some of the basement rooms. In an adjoining room the resistance measurements of the British Association Committee will be continued, while in another, apparatus for the production of liquid air is being set up. The testing of pressure gauges will form an important branch of the work, and for this a mercury column some fifty feet in height has been erected in one corner of the house.

Gas and water have been laid on freely throughout the building—also electricity. A 100-volt circuit is connected to the main dynamo and battery in the power-house, and supplies light. Numerous plug points enable a supply to be taken off for lights for experimental purposes or for small motors. For experimental work a special battery of fifty-five cells has been installed. This is divided into groups of five. Wires run from the switchboard to the various rooms in such a way that one or more of these groups can be switched on to any circuit. Thus voltages between 2 and 110 volts can be obtained as required.

The house is heated on the Webster low-pressure system by steam from a Lancashire boiler in the boiler-house at a distance of about 100 yards. The boiler also supplies steam to one of Parson's 60-kilowatt turbo-generators, which is the main source of power. The power-house also contains an 18-h.p. Crossley gas-engine, driving a 12-kilowatt dynamo by T. Parker and Co. This serves as a stand-by and for charging the main battery of fifty-eight chloride cells.

The engineering laboratory, a building eighty feet by fifty feet, adjoins the power-house. This is divided into two bays; a shaft, driven by a motor supplied by Mather

and Platt, runs along one, and in it will be placed the lathes, drilling machine, planing machine and other tools. The other bay is for experimental work. It is traversed by a 2-ton crane, and will contain a testing machine and machinery for testing steam-pressure gauges, indicators and such instruments.

With regard to gifts to the Laboratory, it has already been mentioned that the Drapers' Company has undertaken to provide the sum of 700*l.* to meet the cost of a Lorenz apparatus, in memory of the late Principal Viriamu Jones. Messrs. Willans and Robinson are providing apparatus for testing steam-pressure gauges and indicators, while in a number of cases very advantageous terms have been granted to the committee by manufacturers of tools and machinery. Lord Rayleigh, Lord Kelvin, Mrs. Hopkinson, and the Syndics of the Cambridge University Press have presented valuable books. Lady Galton has given a valuable astronomical clock with electric contacts, in memory of the late Sir Douglas Galton.

But though much has been done, the Laboratory is far from complete. Rather more than 3000*l.* has been spent on apparatus, but visitors will notice many gaps before the important problems which lie to hand can be fully grasped. Still, it is now possible to make a start, and to show, by the work done with the means at the disposal of the staff, that the Laboratory is fulfilling a need and that it deserves the support of those who are concerned in facilitating the application of science to industry. The pious benefactor, however, who will put it as regards equipment on a footing comparable with the Reichsanstalt is still to seek.

In research work it is hoped that the investigations of the Alloys Research Committee may be continued. Much, though not all, of the apparatus required for this has been purchased; a recording pyrometer, however, must be added to the outfit before it is complete. Prof. Barrett's paper read at the Institution of Electrical Engineers recently showed the importance of the aluminium steels for dynamo and transformer manufactures, and with the kind assistance he then offered it is hoped that a start may soon be made on their investigation.

The measurement of wind pressure is of great importance to engineers; with the help of Sir Benjamin Baker, an investigation will be made into this subject.

In thermometry, the object will be to arrange for the more systematic and ready measurement of the high temperatures met with in industrial undertakings.

As to the commercial testing work which is to be undertaken, the following list will indicate its scope, though until the Laboratory standards have been more thoroughly studied it is hardly possible to do much on a large scale:—

Tests of pressure gauges and steam indicators.

Tests of measuring appliances and gauges for use in engineering shops, &c.

Test of screw gauges.

Tests of thermometers for the measurement of high or low temperature, the platinum thermometer, thermopiles, &c.

Photomicrographic tests on metals, steel rails, &c.

Measurement of the insulation resistance and dielectric capacity of insulators.

Measurement of the electrical resistance of conductors.

Tests of capacity and induction and of various forms of electrical measuring apparatus.

Tests on the magnetic properties of iron, &c.

Standardisation of glass vessels, flasks, burettes, &c., used in chemical laboratories and in various industries—*e.g.* the dairy trade.

Standardisation of weights and scales for laboratory purposes.

Testing of photographic and other lenses.

The director hopes before long to issue a pamphlet giving some account of these various tests, together with a statement of fees charged.

Thus an ample programme has been prepared, and it is interesting to learn on the authority of the director that some slight demand has already shown itself for nearly all the tests enumerated in the list.

PROPOSED ORGANISED RESEARCH ON CANCER.

WE are pleased to learn that a scheme has recently been elaborated in this country for the purpose of systematising and procuring endowment for research upon cancer. In this respect our country is already somewhat behindhand, since a similar organisation has been for some time in full activity in Germany. A large sum of money has been placed at the disposal of Prof. Ehrlich, and a German cancer committee, with Prof. von Leyden as president, is now at work. To this purpose the German Government has already made grants of upwards of 50,000 marks. In America there is a State-subsidised cancer laboratory at the present time, under the direction of Prof. Roswell Park, concerning the work of which some account was given in the *Medical Record* last May. In France, cooperative work upon cancer is also already in progress, a special journal being devoted to the publication of the results.
